

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S. Eng., M.S. Lond
Surgeon to the London Hospital.

PART II.—*Reported Cases of Recovery—Treatment—Conclusion.*

(Continued from page 523, last vol.)

MAX BARTEL'S patient was a man, 50 years of age. His horse fell on him, causing a fracture of the os pubis. Great pain was felt in the right half of the pelvis, with tormenting pain and a feeling of numbness in the stomach, penis, and scrotum. There was great desire, but inability, to pass water. The catheter drew off much bloody urine, and a few drops of urine passed voluntarily. The catheter was used several times daily. At the end of thirty-six hours there was a rigor, and in ten days a swelling appeared above and on the inner side of the thigh. An incision gave exit to urine and decomposing fluid. At this spot a urinary fistula remained. At the end of three quarters of a year the patient went about on crutches; six months later he walked with a stick, and a cure resulted.

Berner's patient was a carter. A wheel passed over his belly. Extensive infiltration of urine resulted, with gangrene and sloughing of the soft parts. The patient was submitted to the *boutonnaire*, and ultimately recovered.

Jeanmaire's patient was a man 50 years of age, who was bruised by the falling of a brick arch. He felt something crack in his belly. An extensive tumour appeared in the right thigh. Ineffectual efforts to make water were always attended by pain in the tumour, which soon reached as far as the knee. The bladder seemed to be greatly distended. A catheter was retained, and drew off bloody urine. At the end of three days urine passed voluntarily, and after thirteen incisions into the fluctuating tumour gave exit to a quantity of urinous fluid mixed with blood and pus. All the urine now came from the wound; none from the catheter. When

the patient lay upon his left side the rent was placed higher than the point of the catheter, and, therefore, all the urine flowed through the instrument, showing that the rent was on the right side of the bladder, beneath the peritoneum. The patient suffered from an attack of rheumatism in all his joints.

Dr. Walker's (a) patient was a temperate man, 23 years of age, caught between an engine and a car. His bladder is said to have been distended. He suffered from collapse, vomiting, and tenderness, and had neither desire nor power to micturate. A tumour appeared in the right iliac region, above Poupart's ligament, reaching nearly to the umbilicus. Fracture of the pelvic bones was detected. The catheter removed six ounces of bloody urine, *with relief, and with disappearance of the tumour.* A rupture of the anterior wall of the bladder was diagnosed, and lateral cystotomy was performed, with *subsidence of the tumour and tenderness.* Improvement and rapid convalescence followed, and in fifty-five days the patient resumed his occupation.

It is obvious that if the patient's bladder was full at the time of the accident, it could scarcely escape rupture during so severe a crush, and satisfactory evidence on this point would do much to establish the correctness of the diagnosis formed by Dr. Walker. Not having seen the original report, I cannot estimate the value of the evidence afforded, and there are several points of interest omitted in the brief second-hand accounts to which I have alone had access. Under these circumstances, I reserve a final judgment. As the case stands, however, I do not comprehend the immunity from the inflammation and suppuration which might have been expected from extravasation of urine through a rent in the anterior wall of the bladder; nor do I see how lateral cystotomy would at once be followed by the outflow of urine already extravasated in front of the bladder, and into the iliac fossa. If the bladder held only a small quantity of urine at the time of the accident, the case would stand thus: Crush between two railway cars; the

(a) "Med. Com. of Massachusetts's Med. Soc." Art. IV., Case 6, Vol. VIII., 1845. Quoted in Erskine Mason's paper. The original is not accessible.

bladder containing only an ounce or two of urine; fracture of the pelvis; six ounces of urine drawn off with the catheter with relief and subsidence of swelling; subsequent retention; distended bladder and effusion of blood mistaken for extravasated urine; lateral cystotomy; emptying of bladder with relief; repair of fracture; recovery. Admission of the case into the list of real recoveries without the most critical examination would be injurious on account of the influence that it would exercise on the selection of a method of treatment in other cases. A strong argument in favour of the tumour having been really caused by the bladder itself, most probably with extravasated blood in front of it and in the iliac fossa, is derived from the disappearance of the tumour on the removal with the catheter of only six ounces of bloody urine. Mr. John Brown, of Burnley, has communicated to me the particulars of a case of an extra-peritoneal rupture, which came under his care a few months ago. The case was an example of the idiopathic variety, and seems to have resulted simply from over-distension of the bladder, occurring without any obvious cause. Not only was there an absence of any history of injury, but the patient was free from stricture, and had not suffered from gonorrhoea. The patient, a lad of eighteen, came from Colne on February 23rd, 1882, and saw Mr. Brown's partner, Dr. Henry Briggs. He complained of wetting his bed at night. Dr. Briggs found his bladder distended after he had made water, and drew off about a pint of urine; he gave him a soft india-rubber catheter, which passed readily, and told him to use it night and morning. On March 3rd the patient returned, greatly pleased, to tell Dr. Briggs that he had not wetted the bed once since he saw him. On March 13th the lad noticed on drawing off his water at night that about a tablespoonful of white matter came. Next day he had considerable pain in the hypogastric region, and passed water frequently. The pain became very severe, and lasted for about a fortnight. Hot fomentations to the lower part of the belly gave him some ease. On the 29th, Dr. Briggs found some swelling of the abdomen, above the pubes, on the outside of the right rectus muscle, and made out fluctuation and dullness. On the 31st, the swelling was more central, and the fluctuation more distinct. The temperature was high, and the pulse 150. Mr. Brown made an incision in the middle line below the umbilicus through the skin and subcutaneous tissue, not reaching the linea alba. A considerable quantity of fluid, which proved to be urine, was evacuated. The fluctuation disappeared and the symptoms improved. On April 5th the opening was unclosed and urine was oozing out abundantly, saturating the towels applied. The oozing ceased for some little time after the patient made water. An india-rubber catheter was passed and retained continuously. The patient made a good recovery. In this case probably frequent over-distension of the bladder led to the formation of a tunicary hernia near the urachus, followed by ulceration of the mucous membrane and effusion of urine between the peritoneum and the abdominal muscles. After mounting upwards to the umbilicus, the urine found a passage by which it came forward into the subcutaneous fascia. Another explanation is the prior formation of an abscess communicating with the bladder; but the fact of extravasation of urine is opposed to this view, for, if a circumscribed abscess opened a communication with the bladder, the urine would be prevented from becoming diffused by the wall of the abscess cavity.

The history of the case, which came under my own observation, though defective in regard to the mode of causation of the communication with the bladder, is as follows:—

Rebecca G., 23, was admitted into the London Hospital on April 6th, 1874, for supposed hip disease. Eighteen months before admission she had fallen down whilst pregnant, and three weeks afterwards she was confined, gave birth to a dead foetus, seven and a-half months

old. Parturition was favourable, but she was ill directly afterwards, and suffered from a constant pain in her side, which continued for nine months. Suddenly the pain removed to the groin, and immediately afterwards the right thigh swelled, and an abscess pointed and broke about two inches below Poupard's ligament on the inner side. Three other abscesses in the same region broke in like manner, and left discharging sinuses. Prior to her admission under my care she had been under various medical practitioners, including Dr. Head, Dr. Palfrey, Mr. Sequeira, Mr. Sawyer, and Mr. Richards, and she had been an inmate of the London, Tottenham, and King's College Hospitals. When she came under me there was a profuse discharge from four open sinuses at the upper part of the right thigh, which was drawn up towards the abdomen, and could not be extended. A week afterwards I placed her under the influence of an anæsthetic, straightened the leg, and explored the sinuses, laying one of them open and inserting drainage tubes in other. I could not detect any diseased bone or hip-joint disease. The leg was put up on a MacIntyre's splint, and a 6 lb. weight was applied. The patient progressed slowly, and on the 8th of June further incisions were made. On the 16th of July a new light was thrown upon the case, as urine was discovered by Mr. Needham, the dresser, issuing from the wound on the inner side of the thigh during distension of the bladder. The patient was averse to submitting to any special treatment for the prevention of the outflow of urine through the sinuses. When she left the hospital she came under the care of Dr. Godfrey and Dr. Todd, and was seen once by Mr. Hilton, who wished to have a catheter retained in the bladder, but this the patient could not bear. After the lapse of some months the communication with the bladder closed spontaneously, the sinuses healed, and the patient gradually regained power over the right leg. She has since borne several children, and at the present time is in perfect health. It is useless to speculate upon the manner in which the aperture in the wall of the bladder was formed, for there is not enough evidence to show whether it was a primary or secondary affection. If primary, the escape of urine through it into the areolar tissue was the cause of the formation of the abscesses; if secondary, there must have been pelvic cellulitis leading to the formation of an abscess, which established an opening into the bladder. Before the abscesses broke externally pus had been observed to pass from the bladder, but this occurrence is compatible with either view.

Since writing the foregoing account of the recoveries after extra-peritoneal rupture of the bladder, I have become acquainted with a successful case reported by Dr. A. V. Williams. (a) The case was one of spontaneous rupture caused by stricture, and strikingly exemplifies the advantage of early surgical interference. Wm. M., 32, of spare habit, but of great endurance, had for several years laboured under stricture of the urethra, with frequent desire to urinate from irritability of the bladder. He stated that on several occasions he had been unable to pass any water for several hours. On the 9th June, 1854, Dr. Williams was called to see him, and learned that the patient had not passed water for two days; that on the morning of the 9th, when making a violent effort to relieve his bladder, he "felt a snap," as if something had given way in his belly, from which time he had no desire to urinate, but was troubled with very great pain over the belly. The doctor tried to pass a catheter, but failed. Rupture of the bladder was diagnosed.

Dr. Willard Parker was summoned in consultation, and it was agreed to make an incision above the pubes, to cut into the bladder and pass a catheter, if possible from within outward through the penis, and re-establish a passage in

(a) Dr. A. V. Williams reported the case in the *New York Medical Times* for January, 1855. The abstract in the text is taken, however from a paper on "Rupture of the Bladder from Stricture," by Dr. J. W. S. Gouley, Surgeon to the Bellevue Hospital, in the *New York Medical Record*, 1872, p. 457. In the abstract no mention is made of the discovery of the aperture in the bladder from which the urine had escaped into the perivesical connective tissue.

that way. It was decided not to cut through the perinaeum, as the extravasation was above the pelvic fascia. The urine flowed out abundantly from the wound; there was but little hæmorrhage. The bladder was deep, and firmly contracted behind the pubes, and so altered in appearance that it could not be recognised as that organ. The doctor pushed up the peritoneum with one finger, and with a bistoury punctured the bladder which Dr. Parker had drawn up with a hook. On dilating this opening with the finger, the internal surface was found corrugated and thickened. The urethro-vesical orifice could not be felt, so that the original design of forcing a passage from within outwards could not be carried out. Whilst the finger was retained in the bladder Dr. Parker passed a grooved sound into the urethra, down to the strictured part, and forced it outward until the point was felt by the finger through the thickened coats of the bladder. A cut was then made through the bladder upon the end of the sound with a probe-pointed bistoury passed along the finger. The lips of the wound made in the abdomen were brought together by a single suture, a catheter introduced through the false passage made into the bladder, an anodyne given, and the patient sent to bed. Urine flowed freely through the wound and through the catheter. With the exception of some local peritonitis, which was readily controlled, the case progressed to a favourable termination without any serious complications. On the 27th day the wound had entirely closed, and the urine was passed through the urethra in a fuller stream than it had done for years.

A HISTORICAL SKETCH OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND. (a)

By ARCHIBALD H. JACOB, M.D., F.R.C.S.,

Professor of Ophthalmology, and Councillor in the College; Ophthalmic and Aural Surgeon to the Richmond, Whitworth, and Hardwicke Government Hospitals.

THE phase of its history which the Royal College of Surgeons in Ireland has entered upon with the year 1883 is one which makes appropriate a historical sketch of its past life, and the very special circumstances under which it is at present placed with regard to medical education in Ireland makes the present epoch peculiarly worthy of note.

With the year 1883 the Royal College of Surgeons enters upon the hundredth session of its most honourable and useful career, and its School of Surgery, being almost coeval with the College, enters, let us hope, with hundredfold energy and zeal upon the performance of the important duty for the discharge of which it is maintained by the College.

On the 16th of February, 1884—before another session of our School has been completed—the Royal College of Surgeons will have completed its century of existence, and will have taken its first step forward into a future pregnant of unknown results to the future of surgery in Ireland. On that day it will possess a School which, I confidently believe, is destined to be the chief instrument for making the Irish surgeon of the future distinguished and respected as he has been in the past, and on that day we shall have in full operation the reformed system of surgical education and examination which has been elaborated by the Council of the College within the past two years, and which has had its first trial within the past few days.

The present moment is, therefore, one in which we may well halt and look back upon the work of those who have gone before, and, having built up Irish surgery, raised this College as a noble monument to their talents, energy, perseverance, and singleness of purpose; they have passed away from us, leaving to us the less difficult but more responsible task of perpetuating the prestige of the College and its School, and carrying on the important work, scientific and

educational, which has been bequeathed to us. While, therefore, we adopt as our motto for the future *Nulla Vestigia Retrorsum*, I think we may acquire courage, hope, and enthusiasm by looking back on the history of this College and of the development of surgery which led up to its establishment, and I therefore propose to devote my lecture to-day chiefly to such a retrospection.

The earliest note which exists of any recognition of surgery in Ireland as an art, science, or profession, was in the year 1446 when a charter of incorporation was granted by Henry VI. to the barbers of Dublin "for the promotion and exercise of the art of surgery." It would seem that even at that remote period Ireland displayed the readiness which has since distinguished her to take a lead in surgical affairs, for I find that it was not until 1461 that English surgeons followed the Irish example and obtained a similar corporate recognition, and that Scotland did not receive the same incorporation until after the lapse of nearly half-a-century, in the year 1505.

In this guild of barber-surgeons women were included, and for one hundred and thirty years, during the reigns of Henry VII., Henry VIII., Edward VI., and Queen Mary, Ireland possessed no better surgical skill than that which could be exercised by the barbers and phlebotomists of the day. In 1576 Queen Elizabeth granted to the Barbers' Company a charter as a "Companie of Chirurgions" under the title of the "Guild of St. Mary Magdalene," which body held possession of surgery in Ireland for nearly two hundred years. It may be conceived, however, that its claim to be considered a centre of surgical culture was but slight, considering that, in the eighteenth century, the said guild consisted of a very limited number of aristocratic exclusionists, most of whom were no more surgeons than a member of the Fishmongers' Company is now a fishmonger. The guild was then, in fact, a club to which few were admitted, and which fulfilled no scientific function whatsoever.

Towards the close of the last century, the State for the first time began to take thought for the surgical care of its Irish subjects. I need hardly remind you that, in those times, no poor relief system existed, and saving the accommodation afforded by Mercer's, Jervis Street, Stevens's, the Meath, and Sir Patrick Dun's Hospitals, there was absolutely no refuge throughout the country for the sick or wounded poor. In 1766 an Act was passed establishing County Infirmarys, which still continue as the centres of surgical practice throughout the provinces; but for ascertaining the capacity of the surgeons who were to take charge of these institutions no means existed, and it became necessary for the Government to form an examining board, for the purpose of testing the fitness of candidates. This board was the first step towards the examining and licensing of surgeons in Ireland, and it consisted of the Surgeon-General of the Army for the time being, the two visiting surgeons, two assistant surgeons, and resident surgeon of Dr. Stevens's Hospital, and the four senior surgeons of Mercer's Hospital, and this board discharged its examining functions until 1786, when its duties were transferred to this College.

On the 29th of March, 1780, the first step towards establishing this College was taken, by the formation of the Dublin Society of Surgeons, by whom the agitation for a Chartered Surgical College was vigorously carried on. The Society had no more pretentious place of assembly than the "Elephant Tavern," in Essex Street, so-called because on the site of the house an elephant had been accidentally burned to death in the year 1681. The first president was Henry Morris, and its first secretary was James Henthorn, whose portrait at full length, believed to be by O'Regan, adorns our board-room. For fifty-two years from the establishment of this Society, until after the grant of the second charter of our College, Henthorn acted as its secretary, and stood forth as a central figure in the history of Irish surgery, and in the movement which led to the foundation of our College. The Dublin Society of Surgeons would seem to have been rather a social

(a) Being an abstract of an Address delivered at the opening of the session of the School of the College, 1882-3.

club than a scientific organisation, for I do not find in its minute book any record of scientific work done. It seems to have been devoted chiefly to emancipating the surgeons proper from their ignominious association with the barbers, for one of its first acts was to fulminate a resolution "That a Royal Charter, dissolving the preposterous and disgraceful union of the surgeons of Dublin with the barbers, and incorporating them separately and distinctly, would highly contribute not only to their own emolument and the advancement of the profession in Ireland, but to the good of society in general, by cultivating and diffusing surgical knowledge."

In order that the College, and school of anatomy and surgery which they hoped to establish, should be constructed upon the best models, some of the members of the Society visited the Continent, and noted the methods of teaching pursued there.

At length the agitation pursued by the Society resulted in the grant, by George the Third, of the first charter of our College, on the 11th of February, 1784—just a century ago. Its first President was Samuel Croker King, grandfather of Dr. Charles Croker King, the present Medical Commissioner of the Local Government Board for Ireland. The preamble relates that—

"We are informed by the humble petition, Henry Morris, William Ruxton, George Daunt, John White-way, Henry Lyster, Robert Bowes, Samuel Croker King, Gustavus Hume, John Neale, Philip Woodroffe, Francis Foreside, William Dease, and James Henthorne, on behalf of themselves and others, principal surgeons of the City of Dublin, that the regulation of the profession of surgery is of the utmost importance to the public and highly necessary for the welfare of mankind, and that the public sustains great injury from the defects in the present system of surgical education in our Kingdom of Ireland, and that the regularly educated surgeons of the City of Dublin, in our Kingdom of Ireland (who are become a numerous and considerable body), find themselves incompetent (from the want of a charter) to establish a liberal and extensive system of surgical education in our said kingdom." The College was empowered (by the agency of its Court of Censors and its Appeal Court of Assistants) to examine "every person who shall have served an apprenticeship of five years to any regularly educated surgeon, and who shall intend to become a member of said College; and if they shall be of opinion that such person so examined is duly qualified to practise surgery, then they shall give such person so examined and qualified as aforesaid the certificate or Letters Testimonial of his qualification to practise, under the common seal of the said College."

The first L.R.C.S.I. was one J. Birch, who obtained the Letters Testimonial on the 17th of August, 1784, and the second was Solomon Richard, afterwards a well-known Dublin surgeon. These gentlemen were examined during two separate days in anatomy, physiology, "practical and operative surgery, and surgical pharmacy."

(To be continued.)

TRANSFUSION—FOR THE HÆMORRHAGES OF PARTURITION.

By CHAS. EGERTON JENNINGS, L.R.C.P. Lond.,
Formerly Resident Accoucheur and House-Physician at the London Hospital.

THE earliest attempts at, and experiments on transfusion—which, from time to time, have been corroborated by actual practice as well as by repetitions of them—conclusively showed that if an animal lose a large quantity of blood the loss *per se* can be successfully supplemented by transfusion from an animal of the same species. Out of a large series of cases (a) it is found that the operation was performed in nearly one-half of them for the acute anemia caused by ante-partum and post-partum hæmorrhage. A positive result was obtained

in two-thirds of this section of these cases, and more than half of them terminated in complete recovery. The accoucheur must, therefore, consider the operation imperative whenever life is jeopardised by severe ante-partum or post-partum hæmorrhage, the hæmorrhage itself having been arrested.

Of all the methods of transfusion, that one which is theoretically the most perfect—immediate transfusion—is practically of the least value, for no means have yet been found to securely provide against the formation of coagula in the apparatus. All the varieties of this method involve an appreciable risk to the donor of the blood, and owing to the complexity and gravity of the double operation, it, as a rule, should only be attempted by a skilled surgeon, with skilled assistance and hospital appliances at his disposal; hence it is only feasible in the minority of the cases of the class under consideration in which transfusion is demanded.

Can transfusion from any of the lower animals be recommended as sound practice? I venture to answer, decidedly not. Many of the heterogeneous transfusions recorded by Hasse and others proved fatal, and it was noticed that those patients who recovered from them only did so after weathering an attack of acute nephritis. Again, the laborious experiments instituted by Ponfick—a series of experiments of too large a number and of too great variety to leave any question for doubt—have shown that to transfuse alien blood in small quantities (whether defibrinated or not) is dangerous, and in large quantities always mortal. These experiments demonstrated the alien to be so acted on by the autochthonous corpuscles that the former were disintegrated, their hæmoglobin becoming dissolved in the plasma. Hæmoglobin in-plasma exerts a peculiar and highly phlogogenic action on the kidney, and the animals transfused by Ponfick from an alien source rapidly presented symptoms of nephritis and hæmoglobin in the urine, with diminution, and afterwards suppression, of that excretion, followed by coma and death. Post-mortem examinations of the animals subjected to experiment disclosed that the kidneys were much swollen, and their tubules, choked with casts, these and other morbid changes, taken with the symptoms observed during life, being not merely amply sufficient to account for death, but also to explain the results obtained by Hasse and his followers.

Moreover, Ponfick ascertained that whilst the transfusion of defibrinated blood to an animal from another of the same species was ordinarily quite innocuous, yet if the blood were frozen and thawed (by which process it would become "laky," and the hæmoglobin liberated from the corpuscles) prior to its defibrination, the intravenous injection of a small quantity of the fluid thus prepared produced hæmoglobinuria with the concomitant train of symptoms, and if the quantity of the fluid injected was large the result was mortal. Here, now, is an explanation why some physicians advocate the transfusion of small rather than large quantities of blood. Is there not reason for suspecting that oftentimes where defibrinated blood has been transfused the corpuscles have become disintegrated during the process, and hæmoglobin-in-plasma injected into the vascular system in a lethal dose?

It must be conceded that indirect transfusion is often applicable where the direct method would be impracticable. On the other hand, the nutritive value of the blood is necessarily depreciated by defibrination. Dr. Braxton Hicks' method meets the difficulty by adding a strong solution of phosphate of soda to freshly-drawn blood; the coagulative property of the blood is minimised, the advantages of the indirect method are secured, and the objection to it is obviated. However, on examining microscopically, on a warm stage, a few drops of blood mixed with a little of Dr. Hicks' solution, it is found that the corpuscles do most rapidly swell out and discharge their hæmoglobin. Must not changes similar to those observed under the microscope

(a) Cf. Ziemssen, "Cyclopaedia of Medicine," xvi, 477.

also occur in a Hicks' transfusion syringe? Is it not open to grave question that an operator, if he adopt this method, may very possibly transfuse a dangerous or deadly quantity of hæmoglobin-in-plasma? At all events, evidence is lacking to show that it is sound practice to introduce abruptly into the vascular system phosphate of soda in proportion far exceeding that which normally obtains in the blood, and I am confirmed in the unfavourable opinion I entertain of this plan of transfusion by the record of four fatal cases treated by the originator of it. (a)

It is of importance to remember that it is the *dynamic* rather than the nutritive value of transfusion which is serviceable in combating acute anæmia. This is well exemplified by the success which usually attends saline intravenous injections (employed as substitutes for blood transfusion). From a perusal of the literature on the subject, from the experience of Dr. Little, when cholera was rife, that saline alcoholic intravenous injections were well-tolerated and beneficial, and from my personal knowledge of this plan of procedure, I am convinced that for combating the effects of alarming hæmorrhage it is an almost perfect substitute for blood transfusion, and, indeed, is, in many respects, superior to that method, for it is always readily applicable, whilst the latter is not; the saline fluid can be procured *ad libitum*, whilst the supply of blood is always very limited, and the risks special to blood transfusion clearly do not exist.

I have published the notes of a case (b) which, in with the best result, sixteen ounces of a saline alcoholic fluid were injected into the median basilic vein of a patient the subject of profuse ante-partum hæmorrhage, the method being adopted not by election, but by compulsion, for although in London, and on a Sunday afternoon, a blood-giver could not be obtained *at a moment's notice*.

To provide a simple and safe and convenient and inexpensive means for intravenous injection, Messrs. Maw, Son, & Thompson have made for me the instrument which is illustrated in the engraving. It consists

the wall of a small glass tube which interrupts the continuity of the rubber near the cannula, and which is necessary for the purposes of observation. The cannula is serpentine in form, and compressed laterally and engraved where it should be grasped by the operator's fingers, that it shall not slip. It tapers gradually to a point, to afford ease of introduction into the opened vein; a point, however, not sharp enough to perforate the walls of the vein whilst lying therein. The aperture for the egress of the fluid is half-an-inch distant from the point of the cannula, that it may be closed by the pulp of the accoucheur's index finger to prevent the escape of the fluid whilst the point of the instrument enters the vein.

A great advantage will be gained by isolating and ligaturing the vein directly it has been fully exposed. The wall of the vein should be grasped with a forceps (to the proximal side of the ligature), and then punctured with the scalpel. By these means any flow of blood from the distal direction will be prevented, and the canula can be inserted into the opened vein as directed. To open the vein with a scissors, as recommended on high authority, instead of with the scalpel, is a needless complication, tending to waste valuable time which the use of an additional instrument must necessarily absorb. I would most strongly urge that the precaution of securing the cannula within the vein by means of a (second) ligature should never be omitted. This ligature will most effectually exclude air from, and prevent the cannula from slipping out of the vein, an accident which has frequently happened, even when assistants have been delegated to maintain the cannula *in situ*. (a)

The instrument is contained in a case which also includes a scalpel, aneurism needle, and dissecting forceps with fine points, a bottle for absolute alcohol, some saline powders, and needles and ligatures. If two drachms of alcohol be added to a pint of water at 100° F., into which a powder of the following composition has been stirred, the obstetrician is at once provided with a means, similar to that adopted in the case quoted, of combating acute anæmia:—

Chloride of sodium ...	50 grains.
Chloride of potassium ...	3 "
Sulphate of soda ...	2·5 "
Carbonate of soda ...	2·5 "
Phosphate of soda (Na ₂ PO ₄) ...	2 "

Since this syphon has been adopted at the London Hospital it has there been successfully employed, and the advantages I have claimed for it have been practically demonstrated. It is applicable not only for the intravenous injection of salines, but also of defibrinated blood, if obtainable. By a simple modification of this instrument (which will shortly be published in a monograph now in the press) it may also be used for immediate blood transfusion combined with saline intravenous injection—the favourable conditions essential for the due performance of the double operation being present—which, inasmuch as it embraces in the highest degree both the *nutritive* and *dynamic* advantages of transfusion, must be regarded as the most perfect of all the methods with which we are familiar. The chief objection to immediate transfusion as now practised—the danger of fibrination in the apparatus—will, by the modification of the instrument I have devised, be abolished, and the risk accruing to the blood-giver will be minimised.

THE Army Medical and Transport Inquiry Committee have recommended their sittings at the War Office. Several men of the Army Hospital Corps and Bearer Companies were examined by the Committee as to the medical arrangements in the recent Egyptian campaign.

essentially of five feet of rubber tubing, to be used after the principle of the syphon or nasal douche, with a bulb for exhausting the air contained in it prior to use; the tubing terminates at one extremity in a bell-shaped aperture, guarded by a metallic grating; at the other in a stopcock, to which a cannula can be "plugged on." Where the syphon passes over the edge of the receptacle the rubber is protected from pressure by a semi-circular canal of vulcanite through which it passes. It has been objected that the fluid, in passing through five feet of tubing, will lose much heat. I find, however, owing to the fact that india-rubber is a bad conductor, only a fractional part of a degree of heat is thus lost. The temperature of the fluid can be estimated sufficiently well for practical purposes by inserting a thermometer in the receptacle, or with unerring exactitude by means of a spirit thermometer constructed in

Clinical Records.

TOTTENHAM TRAINING HOSPITAL.

Two Cases of Empyema.

Under the care of Dr. LICHTENBERG.

Communicated by Mr. SIDNEY DAVIES, B.A., M.R.C.S.,
L.S.A., House Surgeon.

CASE I.—*Empyema—Pneumothorax—Recovery.*—Albert H., labourer, æt. 16, a big, square-chested youth, applied at the Training Hospital as an out-patient, suffering from short breath and general indisposition of two weeks' duration. He was admitted into the hospital on March 20th. On admission the right side of the chest was found to be absolutely dull below the spine of the scapula behind and the third rib in front. On the same side there was loss of respiratory movement and of vocal resonance and vocal vibration, and the breathing was very distant and bronchial. These signs plainly pointed to a liquid effusion, and the diagnosis was confirmed by puncturing with the hypodermic syringe, when pus was drawn off. The patient was treated tentatively for four days, during which time he had a hectic temperature, rising to 101° or 102° in the evening, and falling to normal or thereabouts in the morning. On the 24th the chest was tapped in the seventh costal space in the axilla with an exhausting syringe, and sixteen ounces of pus were drawn off. No marked change in the patient's condition followed the tapping, either as regards the physical signs or the general symptoms; but a few days after the paracentesis had been performed it was observed that the sputa became much increased in quantity and altered in quality. On admission there was a little muco-frothy expectoration. Now the patient filled his half-pint spittoon three or four times in the twenty-four hours with a mucopurulent frothy discharge. At the same time the evening rises of temperature became less marked. The evening temperature on the 30th was only 100°. On the 31st, the chest being examined, the right side was found to be resonant in front down to the sixth rib, and behind to the angle of the scapula. Percussion in the fifth costal interspace gave a cracked-pot sound, and cavernous metallic breathing was heard with the stethoscope. From this time, with the exception of one or two febrile relapses, the patient made a uniform recovery. After the 4th of April the temperature seldom rose above normal. The amount of the sputa gradually diminished, and the patient rapidly regained flesh. He was discharged cured on May 13. There was then fair resonance of the right side down to the sixth rib in front and the eighth behind. Breathing was still distant at the base of the right chest, and the dullness was almost absolute below the eighth rib behind. The only medicinal treatment of importance was the administration of large doses of quinine, which had the effect of slightly reducing the temperature.

Remarks.—There can be little doubt that in this case tapping with the exhausting syringe was the indirect cause of a localised pneumothorax, and that the empyema discharged itself by an opening through the visceral pleura and lung into a bronchial tube. The comparatively small amount of the pus removed by tapping, and the limited extent of the pneumothorax, indicate plainly that extensive adhesions had formed. Probably these adhesions prevented the expansion of the lung to make up for the vacuum produced by the pus removed; the visceral pleura consequently ruptured under the unopposed tension on its inner surface. It is certainly a subject for congratulation that the event proved so favourable, the whole empyema apparently discharging itself through the lungs, leaving only a much thickened pleura behind. The case points to the need of caution in the use of an exhausting syringe. A free incision would probably have been a safer mode of treatment. It is noteworthy that the usual indication of the immediate occurrence of the pneumothorax—viz., sudden severe pain—was in this case absent.

CASE II.—*Empyema—Paracentesis and Drainage—Recovery.*—Samuel B., æt. 6, was admitted into the hospital on August 8th. His history was as follows:—With the exception of measles, he had had no previous illness. His health had been good up till a month ago. About that time he went to a Sunday school treat and caught cold, and next day was seized with a fit. The illness which followed was said to be inflammation of the lungs. He never com-

plained of pain in the side. On admission the child had a wasted, listless appearance, pale face, furred tongue, and very feeble pulse. A physical examination of the chest discovered loss of respiratory movement of the left side, with increased resistance and dullness below the spine of the scapula behind and the fourth rib laterally. The respiratory sounds all over the chest were disguised by loud mucous râles. The patient had a frequent loose cough. Pulse 98; respirations 38; and temp. 101°. On the 14th the mucous râles had diminished, but the signs of effusion on the left side remained the same. The limit of dullness varied when the patient was moved about, but there was no bulging of the intercostal spaces. The chest was accordingly punctured with a hypodermic syringe, and pus was drawn off. The temperature chart now showed an irregular remittent type. On the 13th the evening temperature was 104°, the respirations 52, and the pulse 132. Having decided to perform paracentesis, on the 18th, with the assistance of Dr. Löwe, of Berlin, I made a free incision through the chest wall in the sixth intercostal space, near the angle of the scapula, about two inches in length, and evacuated six ounces of laudable pus. The operation was performed with Listerian precautions, but without chloroform. Considerable difficulty was found in inserting the drainage-tube between the ribs on account of the movement of the latter produced by the child's cries, but finally a tube, $\frac{1}{2}$ in. diameter, was passed into the cavity and carefully secured outside. After the operation the left chest was resonant almost to the base, and the respiration was distinctly heard over the same area. The evening rises of temperature were increased for the first few days after the operation, but after the first week the fever disappeared. On September 11th the drainage-tube was discontinued. Both sides of the chest now moved equally well, but there was still impairment of resonance and distant respiratory sounds on the left side, and a few friction sounds were audible. The boy rapidly gained flesh, and was discharged cured on the 22nd September. Besides the general impaired resonance of the left side, a little patch of dullness persisted round the scar of the incision.

Remarks.—I performed the paracentesis in this case without chloroform, because an empyema greatly increases the danger of apnœa. The only death under chloroform with which I have been concerned was a case of empyema. Certainly the absence of anæsthesia increased the difficulty of the operation, and was, perhaps, one cause why the temperature did not fall sooner. Removal of a portion of one rib would have much facilitated drainage, but such an operation is much more formidable, and could not be done without anæsthesia. Ice was applied to the side of the chest previous to incision, but apparently did not diminish sensation.

Special.

"KRAO," THE SO-CALLED MISSING LINK.

WHEN the showman poses as the apostle of Science, it behoves Science to see that her name is not taken in vain, and that she is not brought into contempt by being made an advertising agent; and as a large number of medical men have been invited by Mr. Farini to a private view of his new exhibition at the Aquarium, it becomes the duty of the organs of medical opinion and science to set forth plainly the nature of that exhibition so that the medical patronage bestowed on it may not be misconstrued into assent to the statements with which it is introduced. Krao is simply an exceedingly hairy Siamese child, and it is unpardonable hyperbole to speak of her as a human monkey or the missing link. Except her extreme hairiness she exhibits no signs of physical degradation below the type of her race, and there is not an idiot school in this or any other country in which children might not be found presenting much more striking simian characteristics or resemblances than any that she displays. She is well formed and intelligent for her age, which is seven years, and it was announced as illustrating her quick-wittedness that she had acquired

the English alphabet in two days. Something was said about her wanting a muscle, which is essentially human, and as to her having two rows of teeth in the upper jaw, but any minute examination of her was out of the question in a crowded assembly containing a number of ladies; and this, at any rate, may be averred, that her movements were perfect, and that the possession of two rows of teeth would constitute her a missing link, not between man and the monkey, which enjoys no such dental superfluity, but between man and the elasmobranch fishes. It is understood that Krao has been privately examined by Professor Flower of the Royal College of Surgeons; and we may therefore look for a clear and trustworthy description of her anatomical development and morphological relations.

We cannot suppose that the puerile story of adventure and of "hair-breadth 'scapes by sea and land" of Mr. Farini's emissaries in their search for the missing link, which is distributed to Krao's visitors, is seriously intended. We take it that it is designed to heighten the dramatic effect of the exhibition, and we need not, therefore, critically examine its traveller's tales about the hairy family of Ava, the Jacoons of the Malacca forests, who live in nests in trees, the tailed men of the Passir mountains, who thoughtfully before sitting down always scoop holes in the ground to accommodate their caudal appendages, or the grand orang-outang old man of Lampun. Without even speculating how Krao has come into Mr. Farini's possession, we may express our belief that she is a member of the hairy family of Siam, photographs of several members of which were exhibited in this country many years ago. It is well-known that the King of Siam bribed a man to marry the first hairy woman in the family, who transmitted the characteristic hairiness to her offspring of both sexes. But whether or not this supposition is correct, we are confident that Krao is simply an instance of that hypertrophy of the hair—*hirsuties universalis*, or *homines pilosi*—which has been noticed by innumerable observers to occur occasionally as a spontaneous variation in a great number of races of the human family. This luxuriant growth of hair is not without its interest in connection with evolutionary theories, but no one has hitherto thought of representing those exhibiting it as survivors of a race of beings intermediate between men and monkeys. The truth is that a copious growth of body hair is characteristic of the higher rather than of the lower races of mankind, and is a distinctive mark of the Semitic and Indo-European families; whereas, amongst the Northern Asiatic Mongols, Hotentots, and Bushmen there is but a scanty or scarcely perceptible crop of hair on the trunk and limbs. It used to be believed that extreme body hairiness was, at least in one instance, a national or tribal trait, and that the Ainos, the inhabitants of Jeyo, Saghalien, and the Kuriles exceeded all nations in the world in this respect, possessing an almost animal-like covering of fur on the upper part of the body. But recent observers have greatly modified this exaggeration, and shown that, as regards hairiness, the Ainos could not even be compared with European sailors. No doubt one of the most permanent physical characteristics of man is his covering of hair; and variations in its colour, length, and distribution, as well as in the form of the hairs, as seen on horizontal section, afford valuable assistance in classifying and determining the affinities of the races of mankind; but instances of extreme hairiness like that seen in Krao must be put in a category by themselves. They are instances of a sport or variation arising we do not very well know how, and capable of transmission to offspring,

and are indeed analogous to those cases of alteration of the cutis, or ichthyosis, which have been noticed from time to time in groups in the same family, as, for instance, in Edward Lambert and his sons—the celebrated porcupine family—who were publicly exhibited in England, France, and Germany in the middle of the last century, and who were doubtless provocative of much learned and ingenious speculation in their day and generation. To quote or adduce such cases, however, in proof of man's descent from the apes is either reckless audacity or profound ignorance. As well might we adduce cases in which children are born *minus* two fingers in evidence of his descent from the three-toed sloth, or cases in which there is a growth of a horny excrescence on the scalp as indicative of his close alliance to the unicorn.

We have said that we are not yet able to explain cases of hypertrophy of the hair, and can only speak of them as sports. But explanations more or less fanciful have been frequently advanced. They have been ascribed to tuberculous and cancerous tendencies, and, of course, to maternal impressions. Thus Elle mentions, although with reserve, that Thomas Ficinus had seen a young woman who was born all covered over with hair and bristles because her mother had regarded too earnestly a picture of John the Baptist clothed in his garment of camel's hair; and the aunt of Pope Nicholas III., it is reported, gave birth to a similar child, because she was in the habit of looking at a boar in the family coat-of-arms. But of all unfounded hypotheses to explain inordinate hairiness, none could be more mischievous than that advanced in the case of Krao. Thousands who look at her—and she certainly presents a very curious and unique appearance—will go away with a crude notion that the problem of the descent of man is solved, and that a showman has struck a fatal blow at orthodoxy. Thousands will think that she is a missing link in the chain of being; whereas she is only a long well-recognised link in the chain of monstrosity.

It is intolerable that the honoured name of Darwin should be connected with the nonsense that is talked about this hairy child. Darwin again and again expressed his belief that the progenitors of mankind became divested of hair at an extremely remote period before the several races diverged from a common stock, and before that common stock became erect. The discovery of a hairy race living in a tropical climate at the present day would therefore be almost more opposed to his theory than in favour of it.

It is impossible to conclude without protesting against the ambiguity, to use the mildest possible term, of the description given of Krao by those who exhibit her. "Although she does not possess an actual tail," we are informed, "she has the rudiments of one." But what human being, we might ask, is without exactly the same rudiment? The allegation that the formation of the lower part of her body is more like that of a monkey than that of a human child is simply incorrect, and the picture drawn of her habits has every appearance of being very highly coloured. As far as could be judged at a brief interview, she is well up to the human standard, and has nothing of the monkey about her. It seems to us that she has good grounds for an action for libel in the manner in which she is described in innumerable posters and advertisements, and we almost wish that she would commence such an action against those who have so ruthlessly "invested her with artistic merit." Scientific evidence, however, does not count for much in our courts of law, and it might, perhaps, be decided, in spite of the unanimous verdict of the Royal Society and Royal College of Physicians and Surgeons, that she is the missing link after all, and is properly designated the human monkey.

THE MEDICAL STAFF IN INDIA.

It is announced that the question of the supply of medical officers of the British service to meet the requirements of the station hospital system in India has recently been under the consideration of the Government, who have decided upon maintaining an establishment of five officers per 1,000 of British troops. From this, therefore, it appears that, instead of a decrease in the number of medical officers, which was held up as one, and indeed a chief, of the grounds for the re-institution of station *versus* regimental hospitals in India, the "new" measure has already rendered a numerical increase necessary. In order to render this the more apparent, it is to be observed that for many years prior to 1841 each regiment of British infantry in India bore on its strength one surgeon and two assistant surgeons. Experience, however, had shown that these numbers were insufficient to meet all contingencies and provide for casualties among medical officers themselves arising from sickness, death, necessary leave of absence, and so on. Accordingly, in that year, a third assistant surgeon was added to each regiment, the strength of such regiment averaging upwards of 1,100 men, so that, in reality, the proportion of medical officers was not quite 4 per 1,000 troops. Here, then, even already, one of the fallacies upon which the scheme of "station" hospitals was based has already exploded. One by one those that remain will each in its turn similarly give way.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

MEDICAL SECTION.

The first meeting of the Medical Section was held, in the College of Physicians, on Friday evening, the 15th December.

Dr. WILLIAM MOORE, President of the King and Queen's College of Physicians, Ireland, occupied the chair as President of the Section.

Dr. A. N. MONTGOMERY, Sectional Secretary, and Mr. WILLIAM THOMSON, General Secretary, were present.

THE PRESIDENT'S ADDRESS.

The PRESIDENT delivered an inaugural address. Having alluded to the absorption of the Medical Society of the King and Queen's College of Physicians into the Academy of Medicine of Ireland as its Medical Section, he reviewed at considerable length the advances made in the diagnosis of disease, particularly within the last twenty-five years. He referred first to affections of the chest, the differential diagnosis of which was now well-nigh perfect. In certain cases clinical observations of the temperature had proved of great use, and the most recent advance was the demonstration by Professor Robertson of the germ origin of pulmonary tuberculosis. To Laennec was due the elucidation of cardiac disease, and to Traube, in great measure, the knowledge of the relations which may exist between these and renal affections. The diagnosis of valvular diseases had become very exact, but the precise value of murmurs as regards diagnosis and prognosis was apt to be over-estimated. Nor was the diagnosis of abdominal aneurism always an easy matter. Great advances had also been made in the study of specific fevers, especially of the endemic fever of this country—enteric or typhoid fevers. Again, much had been done in the localisation of cerebral and spinal diseases, among the more interesting of this class of maladies being hysteria, hystero-epilepsy, and hemianæsthesia. As regards the treatment of some of these affections, he mentioned some remarkable instances in which good results had followed the practice of metallo-therapeut.

LIVING SPECIMENS.

Mr. ARTHUR BENSON exhibited a case of well-marked retinitis albuminuria in a boy, aged 16, without constitutional disturbance; Dr. CHARLES F. MOORE, a case presenting neuralgic symptoms in a man having remarkable patches of

white hair, some of which were congenital; and Mr. STORY, a case of double zonular cataract.

MORBID SPECIMENS.

Dr. J. W. MOORE exhibited by card specimens of diphtheritic inflammation of throat; and Mr. P. S. ABRAHAM, microscopic sections, showing (1) diphtheritic deposit of muscular tissue of the pharynx, (2) mycelium of fungus, and (3) degeneration of muscular fibre in diphtheria.

Dr. WALLACE BEATTY read a paper

ON THE CAUSATION OF LEFT-SIDE PAIN,

drawing special attention to a form not sufficiently recognised, which was due to fecal accumulation, and removed by getting rid of the accumulation. The pain was felt over the lower few ribs on the left side, was associated with extreme tenderness on pressure upwards of the tenth or eleventh rib, scarcely any pain being felt on pressure of these ribs downwards, and was relieved when the side was pressed inwards with flat of hand. He explained its occurrence by the drag of a loaded colon on the pleuro-colic ligament, this constant drag setting up a state of extreme irritability in the nerves of that ligament, so that a painful impression was carried upwards along the left lesser splanchnic nerve to spinal cord, and was transferred by the law of irradiation of sensations to the tenth and eleventh left intercostal nerves.

Dr. WALTER SMITH said the pleuro-colic fold had not received the attention it deserved. It certainly was of considerable importance in the investigation of abdominal disease. Dr. Beatty's arguments were valid as explaining certain kinds of left-side pain, but did not explain all kinds.

Dr. WALLACE BEATTY did not wish it to be understood that he considered left-side pain was caused in every instance by fecal accumulation, but only in cases presenting the symptoms he had mentioned.

UNILATERAL PARALYSIS OF THE SOFT PALATE.

Dr. WALTER SMITH related two cases of paralysis of the left half of the velum palati, and raised the question whether palatine paralysis was invariably to be regarded as a characteristic sequela of diphtheria, or whether it may not occasionally supervene upon non-diphtheritic forms of angina. Case 1 occurred in a young lady, aged 24, and the paralysis developed six weeks after an apparently simple ulcerated sore-throat, for which she had been treated by Dr. Smith. Case 2, a young lady, aged 26, was affected with what was considered to be a simple relaxed sore-throat unattended with ulceration. She remained in a weak and nervous condition, and shortly afterwards the left half of the palate was found to be paralysed. In each case the symptoms were similar—viz., difficulty of swallowing, nasal twang in the voice, and regurgitation of fluids through the nose. Both cases recovered completely. Dr. Smith submitted that it was not unreasonable to hold that catarrhal sore-throat may, now and then, give rise to slight motor paralysis through partial implication of the nervous system, or otherwise.

Dr. HENRY KENNEDY said that diphtheria might exist without exudation. He had seen such cases in which paralysis followed.

Dr. HENRY related a case which he had observed corroborating Dr. Smith's views.

Mr. H. G. CROLY said that the large majority of cases described as diphtheria were really croup.

Mr. WILLIAM THOMSON asked, if paralysis occurred in the palate as the result of specific inflammation, why similar effects did not follow in other parts of the body where nerve filaments were concerned?

Dr. J. W. MOORE alluded to the specimen which he exhibited, describing it as one of phlegmonous erysipelas of the throat in which diphtheritic conditions had supervened. He believed that paralytic symptoms occurred only in true diphtheria.

Dr. FINNEY considered the fact that other diseases were associated with paralytic symptoms confirmed Dr. Smith's view.

Mr. W. STOKES doubted that paralytic symptoms followed inflammation other than those of a diphtheritic nature.

The PRESIDENT regretted that no information had been given as to the presence of albumen in the urine in Dr. Smith's cases.

Dr. R. A. HAYES mentioned, in support of Dr. Smith's view, a case in which chronic inflammation of the palate, resulting from excessive tobacco-smoking, gave rise to paralysis of the palate.

Dr. WALTER SMITH, in reply, said that the paralysis in these cases might be the result of myelitis or of muscular degeneration. He answered Mr. Thomson's question by pointing out the rich nervous supply of the palate, and the muscles being open to attack from both sides. The Section then adjourned.

MEDICAL SOCIETY OF LONDON.

DECEMBER 11TH, 1882.

INVALID CARRIAGE.

Mr. RICHARD DAVY, F.R.C.S., exhibited to the Society an invalid carriage that had been built under his own supervision, capable of carrying one, or, at an emergency, six injured persons, in addition to the surgeon in charge and the driver. Mr. Davy having drawn attention to the imperative necessity of conveying invalids with safety and comfort, stated that his system of carriage accorded to human beings the conditions that had been recognised as of value to furniture, viz.—the careful placing of the patient at his own door on a bed in the carriage, and not interfering with him until his door of destination be reached at the other end. He divided his essential conditions into two—1st, those required by the patient; 2nd, those required by the surgeon in charge. 1st. The carriage must be of one horse-power, able to be shunted on to a steamer or railway track; of large cubical capacity; of a level low enough to clear bridges on the line; of quiet appearance; admitting plenty of fresh air, light, &c.; having a door forming a platform for easy ingress or exit; in short, a carriage which will allow the details of a sick room to be nicely carried on within it. The stretchers must be comfortable, strong, and easy, to be slung to the roof—Mr. Davy prefers a hammock stretcher. His assistants are trained in the necessary drill. Journeys not exceeding twenty miles one way might generally be undertaken by road; beyond that distance steam should be utilised, and the quicker the speed the better. 2nd. The surgeon requires ample space, a floor easily cleaned, and ready communication between the driver and himself. A large cupboard underneath the driving-box carries lint, bandages, splints, brandy, and general provisions. Curtains must be simple and easily worked; door strong and of wide dimensions. Light inside must be given by a fixed or hand lamp. Mr. Davy drew particular attention to the exorbitant rates charged by the railway companies, and stated that he believed that the G. W. R. Co. had in their possession the most miserable invalid coach that he had ever seen. The multiplicity of varying railway companies in Great Britain caused great inconvenience,

met with any mishaps. On all grounds, relief has been gained by uplifting patients from the machines vested in cabmen, carriage proprietors, and railway companies, and substituting a system requiring no change of the invalid in place of one necessitating many; and he pointed out the great comfort to the patient in adopting the arrangement of travelling from his own door in town to his own door in the country (on his own bed or sofa) with the minimum amount of risk and maximum amount of comfort. Mr. John Burt, of Swinton Street, King's Cross, has carefully executed the whole of the carriage work; and those Fellows who made trial of the run of the carriage expressed approval of its lightness, ease, and working capacity. The diagrams illustrate an outside and inside view of the van; also (A) a suspended hammock, and (B) the line of two canvas litters.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.
MONTHLY MEETING.—DECEMBER.

Mr. S. LEE RYMER, L.D.S., in the Chair.

The greater part of the evening was occupied with the discussion of the paper read at the previous meeting by Dr. A. CARPENTER, of Croydon, on

THE CAUSES OF DENTAL DECAY.

It was begun by Mr. OAKLEY COLES, who said that Dr. Carpenter's statement that so-called "dead teeth" were more liable to decay than others did not agree with the ordinary experience of the dental profession; nor would his assertion that the subjects of inherited gout were very liable to caries; such people generally had large, strong teeth, which were but little liable to caries, but which were liable to be cast off by recession of the gums, or as the result of chronic congestion of the alveolo-dental membrane. Dr. Carpenter apparently had not observed any connection between rheumatism and caries, but it was well known by members of the dental profession that acute rheumatism was liable to be followed by the worst form of decay—that known as "soft caries."

Mr. HENRY SEWILL said it seemed to be implied in the paper that the causes of dental decay were doubtful or unknown; but, as a matter of fact, there was no mystery about them. The predisposing causes were such as led to structural defects in the teeth; there was no doubt that syphilis was a cause of defective teeth, but he was strongly of opinion that gout had no predisposing influence whatever. There could be no doubt that caries itself was wholly due to the action on the teeth of the acid products of decomposition formed in the mouth, which permeated the porous enamel and acted on the dentine. It had also been lately shown that the progress of the disease was assisted by the proliferation of micro-organisms in the canals of the dentine, these organisms having themselves the power of producing an acid secretion. It was not in any sense a constitutional, but a purely local disease.

The discussion was continued by Mr. REDMAN, who suggested that Dr. Carpenter had omitted to mention one predisposing cause of caries—viz., the use of carefully-cooked and soft food, it being a well-known law in physiology that any organ not fully used would deteriorate; and by Mr. HENRY, who asked whether it really was an established fact that dental caries had become more prevalent? No doubt it came under observation more; but might not this be due to the fact that more attention was now paid to the preservation of the teeth?

Mr. COLEMAN and Dr. WALKER both gave it as their opinion that the increase of caries was an undoubted fact. The latter dissented from Dr. Carpenter's statement that gout was a cause of caries. He thought that improper food in infancy was one common cause of defective teeth, and agreed with Mr. Redman that their comparative disuse in mastication was another.

Mr. HUTCHINSON also thought that the artificial life led by mothers, and the injudicious feeding of infants, were two of the chief causes of the prevalence of bad teeth.

Dr. CARPENTER then replied at some length, saying that his statements—particularly with regard to gout—were founded on careful personal observations made in the course of forty years' experience of medical practice. He admitted that rheumatism exerted an influence on the teeth, but thought that this part of the subject required carefully working out. He quite agreed that the improper feeding of children was a very

which could only be got over by Government centralisation. Mr. Davy stated that his system of carriage had been appreciated by invalids; that much care and forethought is required in conducting any shift; and that he had never

common cause of bad teeth, but could not admit that the etiology and pathology of dental diseases were as yet quite as satisfactorily explained as Mr. Sewill claimed that they were.

Mr. CHARTERS WHITE afterwards read a paper on "The Salivary Glands of Insects."

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 3, 1883.

SHIP SURGEONS.

FOR a considerable time past attention has been occasionally called to the miserable inefficiency of the regulations observed on board passenger ships in respect to medical attendance, and particularly as regards the position and accommodation given to surgeons placed in charge of such vessels during a voyage. The Manchester Medico-Ethical Association has recently discussed the matter again, with the result that unanimous acceptance of a resolution proposed by Dr. Irwin to the following effect was given—viz., "That the medical and sanitary departments of our mercantile marine are in a highly unsatisfactory condition, by which the lives of passengers are frequently endangered." Further, the same Association decided "to press upon the Government the necessity of immediate inquiry into the position, status, and efficiency of surgeons upon passenger ships."

The need for some such action as that which is indicated by these resolutions has already been abundantly shown, and we cannot but believe that when the full facts are once laid in all their significance before the proper authorities, the pressing nature of the whole question will at once be admitted. The public, moreover, is vitally interested in the immediate institution of such reforms as shall secure for passengers on ocean-

going steamers advantages in the way of medical attendance in some sort approaching to those enjoyed on land. As it is at present, there is no possibility of this being so. Anybody with a qualification admitting to the Medical Register may be accepted for the post of ship's surgeon, and any kind of lodgment on board is considered good enough for the officer who is entrusted with the care of human life, while in the matter of arrangements for enabling him to carry out the duties of his responsible position absolutely nothing is, as a rule, done, even on the best appointed vessels, to ensure efficiency and comfort. Dr. Irwin relates how, on what it regarded as the most magnificent steamer afloat, the surgeon's cabin is a mere box, less than six feet square, unlighted, unventilated, and within a yard of a series of closets, and in this den the medical officer—in charge of, perhaps, between two and three thousand people—is expected to discharge the onerous professional duties that may fall to him to undertake during a voyage across the Atlantic!

In keeping with the miserable accommodation afforded to them is the remuneration received for their services by ship-surgeons; and naturally, also, the position and status they enjoy are correspondingly low. That a remedy for such an undesirable state of things is demanded in the interests of the profession and of the travelling public alike is abundantly clear; but it is still more strikingly apparent in the fact, dwelt on by Dr. Irwin with the insistence its ominous meaning calls for, that death-rates on board ocean-going steamers are *in excess*—often largely in excess—of the annual mortality in towns which exhibit the highest rates.

There is every intention on the part of its initiators to maintain the agitation now commenced in favour of speedy reform of the shortcomings complained of. The public, too, is being slowly but surely encouraged to investigate the conditions under which it is required to risk long sea journeys as matters are at present; and in proportion as the dangers and difficulties of the system appeal to the senses of the people, a strong and irresistible demand for improvement will be excited against which owners and agents will find it impossible to contend. We shall gladly lend assistance in bringing about the changes that are both necessary and just, and we do not doubt that the importance of the whole subject will obtain for it a due amount of consideration, even from the supreme legislative assembly of the country.

THE TYPHOID EPIDEMIC IN PARIS.

NEVER has a more favourable opportunity occurred for the study of typhoid fever relative to its cause and treatment than that which is afforded by the present epidemic in the city of Paris, and medical men at home and abroad will not fail to profit by the result of the researches that are now being prosecuted with commendable zeal and energy, which will not only throw additional light on the many questions already too obscure attached to the disease itself, but what will be far more profitable to succeeding generations, on the best prophylactic measures to be adopted against it. Already the different sections of the medical bodies in Paris have devoted whole meetings

to the discussion of the subject, and much interesting matter has been developed. But, unfortunately, the issue of their deliberations only tends to show that medical opinions are as widely different as ever on the most important points; yet no blame can be attached, nor any light criticism passed—never were medical men more conscious of their responsibility before the public, and never more anxious to arrive at the truth. Paris has never been free from typhoid fever; every year it has carried off its victims; but up to August of the present year it has only existed in the endemic form. Other zymotic diseases, such as diphtheria (which seems to be gaining ground every year: from 1869 to 1874 there were 53 deaths for 100,000 inhabitants; at present the number has doubled, being 101), small-pox, scarlatina, measles, have become more frequent, and, as M. Brouardel has proved, there is a constant periodic increase of all contagious diseases. Yet Paris cannot be regarded as an absolutely unhealthy city, though, in a sanitary point of view, it must be considered inferior to many other European cities. Medical men are not blind to that fact, as they admit it and deplore it. The causes can be easily defined, and will be found in the air, the water, overcrowding, bad drainage, and perhaps a certain reprehensible laxity in the application of sanitary regulations. The air of Paris is by no means what might be termed bracing; on the contrary, it has an enervating effect, especially on those who have not had time to become acclimatised. The stranger entering the city perceives its effect at once; and unless in certain quarters, as Auteuil, the heights of Montmartre, and Belleville, the atmosphere, which seems to be deficient in ozone, is rendered, to a certain degree, impure by the emanations from defective drainage. The fact of the climate of Paris being below the standard accounts for the relative frequency of typhoid fever amongst those who have immigrated. However, a more powerful cause of the present epidemic will be found in the overcrowded state of the dwellings of the poor, especially in the *garnis*, or lodging-houses. It need hardly be stated that the houses in Paris are let in *étages*, or flats. Seldom, even by the rich, except in the most eccentric quarters, is a whole house occupied by one family. These houses contain generally four *étages*, and often five, and it is only the well-to-do who can afford the luxury of possessing a whole *étage*. The poor hire two rooms, or even one; thus, each flat might contain ten families, which would make forty for the whole house. Allowing four persons to each family—and the number is, if anything, below the average—we have 160 persons in one house. This is not an unfrequent number, especially in the *garnis*. The evil effects of this overcrowding are obvious, and are increased by the filthy habits of the lodgers, who are not in general French, but Italians and Germans. These foreigners come to Paris in search of work, and they infest, if not infect, the working quarters, as Grenelle, Meuilmontant, and Belleville. To use the words of M. Rochard, typhoid fever is the daughter of overcrowding and dirt. In 1875 there were 9,000 lodging-houses in Paris, with a population of 142,600; in 1882 the former were increased to 11,000, and the population rose to 243,560. These people have no idea of cleanliness; they seem to revel in dirt. The

walls of their houses are in the most filthy condition, and huddled together as they are, frequently all in one room, it is not surprising that the abode becomes the hotbed of contagion. M. Marjolin called the attention of his colleagues, at a meeting of the Académie de Médecine, to this serious condition of several parts of Paris, and on the disastrous influence it exercised on the population at large, and to which he attributes the present epidemic. Another cause not less powerful in its deleterious effects is the system of drainage, which is very defective, both inside and outside. In the infected lodgings of the poorer quarters of the city, the air one breathes on entering is highly charged with the odours exhaled from the water-closets, which are, in nearly all cases, placed on the stairs of each *étage*. In the warm weather the effect is overpowering, and the streets are almost impassable. Living under such circumstances engenders those epidemics which harass a city so much. Outside the drains are insufficient, and communicating with each other; the most healthy districts are not safe, as has been recently proved. The evacuations of the typhoid patients are carried along, and by the system of inter-communication the germs or specific matter of the disease—which is the immediate cause of contagion according to the most eminent medical men—is conveyed long distances, and invades dwellings hitherto healthy. Also when in summer there is a scarcity of water the sewers are insufficiently flushed, and consequently deleterious gases escape through the openings into the streets, contaminating the air. One other cause must not be omitted from the series, as to it, according to MM. Lancereaux and Rochard, the present epidemic is to be attributed, and that is the water, which M. Gueneau de Mussy affirmed before the Académie de Médecine to be charged with animal matter in a state of putrefaction and other impurities, which render it unfit for drinking purposes. It must certainly be admitted that Paris water is far from what it should be, and from what might naturally be expected to be found in the city styled the "centre of civilisation." In summer it is not potable, and unless boiled or properly filtered, causes diarrhœa or dysentery. Two streams supply the greater part of the town, the Dhuis and the Vannes, whose waters, although not free from impurities, are yet drinkable; but when the warm weather sets in the supply of water is diminished, and to meet the wants of an ever-increasing population the contaminated waters of the canal or the Seine are substituted, so that it is not surprising that the autumn brings an increase of zymotic diseases. Sir Richard Wallace, with the generosity which has always distinguished him, conferred, by means of the drinking fountains which he caused to be erected all over the city, the greatest boon that could be bestowed on a people who otherwise were compelled, in order not to drink the warm water furnished by the town, to resort to the *cafés* to quench their thirst in sour wines. These fountains, called by the Parisians, "Fontaines Wallace," are mainly situated in the populous working quarters, and every summer evening crowds of men and women may be seen regaling themselves in its cold refreshing stream. Thus it may be said that the water furnished by the Municipal Council is not only of a very inferior quality, but highly dangerous in the summer time, and

capable of engendering an epidemic such as has just been witnessed. As to the laxity of sanitary regulations, the fault lies not with the Government, but with those who have been entrusted with the execution of the health laws.

As has been already said, typhoid fever has always been endemic in Paris. Every week from twenty-five to thirty deaths were recorded, but it was always observed that in the month of July a larger number of deaths were due to its influence, at times simulating a slight epidemic. On the 4th of August the fever began to assume an abnormal development, and in the succeeding week ninety-eight deaths were recorded, the eighteenth, nineteenth, and tenth arrondissements being the first attacked, and towards the middle of September the epidemic became general over Paris. The mortality rose to 250 a week until the 26th October, when the fall took place. Thus from the 4th August to the 26th October the number of victims was 1,358, which may be divided, as regards the sex, into 763 men and boys, and 595 women and girls; that is to say, 128 persons of the male sex succumbed against 100 of the female sex during the three months of August, September, and October. As to age, 20 boys against 31 girls died under 5 years, 68 against 139 under 15, 554 men and 360 women between 15 and 35, while 9 men and 8 women died over 60. From these numbers it will be seen that the female sex were attacked at an earlier age than the male. M. Pietra de Santa, in a communication read before the Académie de Médecine, considered the epidemic grave from the large number of deaths. For the first six months of the present year the typhoid deaths amounted to 919; for the following three months the mortality was 728; and for the month of October alone, 628 deaths were registered, which gave a total of 2,285, a number already superior to the sum total of the previous year (2,130). The characteristic symptoms of the disease as seen in the Hôpitaux Necker, which provided a large number of beds for the reception of typhoid patients, are worthy of notice for their apparently mild type. Apparently, we say, for in many instances this mildness was deceptive. The temperature rarely exceeded 104, and the fever which in the first septenary went on increasing, remained stationary during the second, and in the last two, was oscillating, or affected a remittent form. In several cases the temperature after the patient was supposed to be entering on convalescence rose suddenly and the fever continued during several days with, in fact, all the symptoms of typhoid fever, eruption included. This phenomenon M. Potain, of the Necker Hospital, would not call a relapse, but a *reiteration* resulting from the primitive intoxication. The ataxic form of the fever was exceptionally rare, but in many cases the *jours critiques*, or crisis were retarded to the 24th, 26th, and in some cases to the 40th day. The abdominal symptoms were in general of a very mild type, although two cases of peritonitis were observed which terminated fatally. The most frequent complications were to be found in the respiratory apparatus, the affections observed being laryngitis (ulcerative), bronchitis, pulmonary congestion, and pneumonia. One case terminated fatally from pleurisy, and another from gangrene of the lung. As to treatment it differed widely

in the several hospitals each man adopted his own and had success which encouraged him to consider his method as the best. In any case the mortality (14 per cent.) was not excessive considering the large number of cases treated. M. Hérard goes in for quinine in large doses, forty to sixty grains a day, but two sudden deaths having occurred under this treatment he was attacked by M. Hardy who expressed the opinion that the quinine in such heroic doses was the cause, however M. Hérard, and in this he was seconded by his other colleagues, repudiated such an assertion, citing authorities in support of this view. M. Vulpian prefers salicylic acid which he gives in five grain doses every half-hour. Under the influence of this treatment the temperature lowers in 48 hours from 3 to 4 degrees, at the same time a very notable amelioration in the general condition of the patient was observed. In some cases, especially amongst boys, he had seen cerebral salicylism with a little delirium. At the same time M. Vulpian does not pretend that the duration of the disease nor the mortality are diminished, but he considers that salicylic acid is one of the most energetic moderators of typhoid fever that we possess. The treatment of M. Lancereaux approaches very closely the treatment most generally adopted. Baths at 83 lowered easily the temperature one degree or more, with the baths he gave digitalis to control agitation or sleeplessness, opium was administered, the opium and digitalis were associated with very good results in the ataxic forms. The meteorism was treated by purgatives, cold enemas, and ice, respiratory complications by cupping and ipecacuanha. Against the fetid character of the stools phenicated enemas were given. Upon 52 cases thus treated he lost but 5. It will now be seen that in spite of the different antiseptics and antipyretics recently vaunted the tendency has been in general inclining to the old classic method of purgatives and treating symptoms.

ENTERIC FEVER IN LONDON.

TAKING the cases returned as of "enteric" fever during the last few weeks, the fact transpires that the deaths by the affection or series of affections so designated have numerically increased as compared with the weeks immediately preceding, and also that they are in excess of averages for the corresponding weeks of the last ten years. The question naturally arises—How is this increase to be accounted for in accordance with the defective sanitation theory, considering that in all that concerns sanitation so much has been achieved since 1872? The fact appears to be that the theory in question is, and always has been, insufficient of itself to explain the occurrence of this particular form of fever, and of some other so called *zymotic* diseases; and, indeed, this is now coming to be acknowledged to be the case. Carefully prepared statistics show that the number of deaths assigned to "enteric" fever presents a rise and fall in accordance with the progress of the seasons; and that the regularity of this rise and fall, like the recurrence of the seasons, is more or less constant from year to year. The mortality is above the mean from about the middle of September to the end of January; it then, after fluctuating about the

mean for a week or two, falls below it for the remainder of the season. Since the 39th week of 1882—namely, that ending September 23rd—the gradual rise in the line of mortality by “enteric” fever has been in accordance with its usual law; and from that date till the end of the 49th week—namely, that ending December 7th, 1882—the weekly and general mortality has been considerably greater than that of the preceding ten years. According to some observers, the type of the disease has also increased in severity as compared with the average of the previous years just alluded to. From these considerations, therefore, the conclusion to be drawn is that the influences and conditions upon which the occurrence, propagation, and subsequent decay of the disease in question depend are in their nature recurrent, periodical, and of a nature not to be reached by the simple observance of what is commonly included under the head of “sanitary” measures. Are we, then, to revert to “epidemic influence” for so long discarded in order to account for the phenomena of the “epidemic” now prevailing, although, fortunately, not to a great extent in the metropolis? It is true, the condition so indicated is only manifest by the presence among us of a particular form of illness; yet it may become possible hereafter, by means of carefully conducted observations, to obtain at least some insight into this and other influences which affect public health in different degrees and ways, according to season and period of the year. Whenever the normal characters of a particular season are departed from, the prevalence of epidemic disease usually incidental to that season is affected; and when, as recently has happened, unusual mildness prevailed, diseases incidental to other periods of the year than winter have manifested themselves.

Notes on Current Topics.

Quackery in America.

ACCUSTOMED as we are to consider the States as the Elysium of quacks, the records of the doings of these pretenders published from time to time arouse a feeling of increased astonishment at each revelation. Beplagued by its army of sham practitioners, and abundantly spotted with villanous institutions whose founders drive a profitable trade by selling bogus diplomas, the United States may well be considered to deserve the sympathy of all who are able to appreciate the frightful mischief annually done to the population by uncontrolled practitioners of every conceivable shade of humbug. In Missouri, which the *New York Medical Record* describes as a “quack ridden state” (what about New York itself?) there are 4,834 practitioners of one kind or another, one doctor to every 450 inhabitants. Of these, 3,453 “belong to regular medicine,” “and over 1,300 are eclectics, homœopaths, and nondescripts. But hardly more than one-half (2,456) are graduates of regular schools.” In addition to these facts, which are quoted from a paper by Dr. King, President of the Missouri State Medical Society, the author of the communication referred to declares that 269 of the practitioners are abortionists, 1,904 are deemed by com-

petent judges to be incapable of practising medicine intelligently, and 452 are persons of immoral character, 34 being women. The accounts of the damage perpetrated by this army of rogues, however, is most instructive. It includes 5,570 lives annually lost through quackery in the State, in addition to 8,000 children killed *in utero* by the 269 abortionists; the yearly sum paid for these services reaches somewhere about half a million sterling: verily a pleasing reflection for those who love their species! Some of the instances of cure performed or promised by quacks are interesting from a professional point of view. They are, many of them, curious in the extreme; occasionally they are unique, as for instance the promise of a “medical man” who undertakes to cure nasal catarrh at one sitting, and in proof of performance, “remove the catarrh and place it on a saucer.” English quackery has not yet reached the perfection of American samples. Long may it continue to hold a position of inferiority.

The Next International Medical Congress.

PROBABLY none who were privileged to attend the great representative Congress of all nations which was held in London in the summer of 1881 will ever forget it, either for its magnitude, the voluminous, and at the same time, practical character of its communications, or for the unbounded hospitality which was shown to its members by private individuals and public corporations. Before separating the question arose as to the next meeting, and as Copenhagen had put in a claim to be honoured with the next assemblage, a committee was appointed, and that city has now been definitely decided on. We are authorised to state, therefore, that the next International Medical Congress will be held in Copenhagen from the 10th to the 16th of August, 1884; early notice being thus given so that corporate bodies, societies, and private individuals may make their arrangements without clashing.

The Dangers of Keeping Anatomical Specimens in Consulting Rooms.

THE Hon. A. B., a valetudinarian of 65, went to consult a leader of science. The physician was out, but his valet announced that he would be in soon, and, on learning the position of the client, introduced him into his master's private sanctum, so that he might have the benefit of consulting him out of his turn. To pass away the time, the patient examined the room, and discovering in one corner an excellently mounted and complete skeleton; imagination immediately suggested that this was probably an old patient of the doctor's. He flew at once to the hall-door and rapidly vanished, to the astonishment of the servant and the subsequent annoyance of the physician.

The London Society of Apothecaries.

THE Society of Apothecaries of London, at a recent meeting of its Court, decided to found two scholarships to be competed for by members of the medical profession, one in clinical medicine, therapeutics, and hygiene; the other in surgery. The conditions under which these prizes are to be held and the restrictions of competition are not yet announced, but early information on all points relating to amount, terms, and all other particulars, is promised.

Tracheotomy.

DR. H. M. RICHARDSON, writing on tracheotomy in the *Boston Medical and Surgical Journal*, after reviewing the methods of performing the operation adopted by different surgeons, thus sums up his conclusions:—(1) The point of election is just below the cricoid isthmus. (2) The isthmus of the thyroid, if recognised, should be pushed down, the cervical fascia of the median line having been first incised, and the trachea exposed by carefully separating the parts with a director; or, (3) The thyroid isthmus may be entirely disregarded, and the parts freely incised, in which case all hæmorrhage should be checked before opening the trachea. (4) Deliberation, careful dissection, and a bloodless operation are better than the gain of a few seconds at the expense of hæmorrhage into the trachea. (5) Ether should be used except in extreme asphyxia.

The late Mr. Goyder.

At a meeting of the principal members of the profession in Newcastle-on-Tyne, held on Friday evening in the library of the Infirmary, it was resolved to found a clinical scholarship, to be called the Goyder Scholarship, in memory of the late C. M. Goyder, L.R.C.P., M.R.C.S., a distinguished student of the Newcastle school, and for some time resident medical officer of the infirmary. Mr. Goyder had not long been engaged in private practice when he contracted typhus fever, and died after only fourteen days' illness. His loss is very deeply regretted by all his medical brethren, who entertained a warm personal friendship for him, and a high appreciation of his professional abilities. They have therefore decided to give expression to the opinion they held of his merits in the way referred to above, believing that thus may the bright example of Mr. Goyder's life be best kept in view in future, to act as a stimulus to other students to emulate his character and achievements.

Dwarfs.

ANNA MINERVA SHEARER, a child monstrosity, an object of curiosity to thousands of visitors, died recently at her parents' home in Pennsylvania. The child was ten years of age, and weighed only fourteen pounds; was blind all her life, unable to walk or talk. A sister, aged thirteen years, weighs twenty pounds, and is in the same condition. The parents are full grown, healthy, and strong, and the father is a blacksmith. The children's only sense was that of hearing, and they had to be attended to like infants.

Birmingham Hospital Sunday.

THE total sum collected in Birmingham, the home of the movement, on "Hospital Sunday," amounted to £5,152. This is in excess of previous collections, and has been distributed among the various medical charities in proportion to their respective expenditures.]

† THE next examination in dental surgery at the Royal College of Surgeons in Ireland will be held on Monday, 12th March, and following days. Candidates must forward certificates to the Registrar, at the College, on or before Thursday, 22nd February, 1883.

The Dublin School Returns.

THE Anatomical Committee has had its usual meeting to receive the returns of students dissecting at the various Dublin schools, which are supplied to them in order that they may allocate subjects to the schools as required. The returns for the past three years are as follows:—

	1880-1.	188-2.	1882-3.
School of Physic...	192	216	225
Royal College of Surgeons	189	140	132
Ledwich School ...	230	221	230
Carmichael College	149	159	134
Catholic University	94	100	118

Certain points in connection with these returns need to be taken into account before forming any judgment thereon. In the first place, the numbers represent dissectors only, and not the entrants at any school. Secondly, the numbers are those furnished by the school registrars, and it is a well-known ruse for certain schools to make returns largely in excess of their real class, in order that they may have an abundance of subjects, and look well in the list. In such cases the names of all sorts of chronics and perpetuals are returned, while other schools only set down the names of students actually entered for the current year's dissections. Lastly, it is well known that in the School of Physic and College of Surgeons schools no student is entered until he pays the entire fee, cash down, in advance; and in the Carmichael College the greater part of the fee must be paid; while other schools accept a small payment on account, and the balance whenever the certificates are taken out, from which it results that these institutions are largely patronised by students who do not choose to bind themselves by a heavy payment to go on with the profession.

Perforation of the Ileum by Worms.

DR. T. J. CROFFORD reported at the last meeting of the Mississippi State Medical Society the case of a boy (coloured), aged eight, who complained of pain in the right iliac region, had fever for eight days, and died, having passed several round worms three days before death. At the autopsy the ileum showed two perforations, one twelve, the other twenty-four inches above the ileo-cæcal valve, and the peritoneal cavity contained half a pint of pus and two lumbricoid worms, each ten inches long. One of the worms was between the liver and diaphragm, partially decomposed. The edges of the perforations in the bowel were covered with lymph.

Death of a Centenarian.

THE death is announced, at the Protestant Retreat Drumcondra, near Dublin, of Mrs. Mary Murray, at the age of 110 years. She was a native of the county of Derry, and for many years carried books about for sale, throughout the entire province of Ulster and many portions of Leinster. She was a very tall, strong woman, and was admirably fitted for the wandering life she led previous to her admission to the Retreat. Mrs. Murray is said to have been fond of a glass of punch, and smoked a very black dhudeen up to a very few years ago.

Dr. H. Macnaughton Jones, of Cork.

A SPECIAL meeting of the General Committee of the Cork Fever Hospital was held on the 21st ult., to receive the resignation of Professor H. Macnaughton Jones, as senior physician to the hospital. For the past eleven years, Professor Jones has been attached to the institution, but found it impossible, in consequence of new professional engagements, to discharge the duties satisfactorily for the future. The following resolution was unanimously adopted: "That the resignation of Dr. Jones be accepted and his letter of resignation entered on the minutes, and the committee are unanimous in their expression of regret at losing the valuable services of Dr. Jones, who has been so long and honorably connected with the institution; and they hope that his future career will be as distinguished and successful as his past."

The Public Health.

NOTWITHSTANDING the mildness of the winter so far, there appears to be a good deal of sickness about, and the rates of mortality last week in the large cities of the United Kingdom were in most cases above the average. Of the thirty large towns, Derby has the lowest death-rate, 20·0 per 1,000—and Liverpool the highest, 40·1 per 1,000. The other towns may be thus summarised:—Leicester, Edinburgh, Portsmouth, Bristol, and Brighton, 21 per 1,000; Bolton, Birmingham, Bradford, Salford, and Blackburn, 23; Nottingham and Cardiff, 24; Wolverhampton and Birkenhead, 25; Halifax, 26; London, Norwich, and Sheffield, 27; Sunderland, 28; Hull and Oldham, 29; Leeds, 30; Manchester, 31; Preston, Plymouth, and Newcastle-on-Tyne, 32; Huddersfield, 36; Glasgow, 37; Dublin, 38. The highest annual death-rates from diseases of the zymotic class in these towns last week were—from scarlet fever, 1·6 in Sheffield and 1·9 in Brighton; from measles, 1·9 in Liverpool and 2·6 in Sunderland; from whooping-cough, 2·1 in Plymouth and 2·4 in Cardiff; and from "fever," 1·3 in Derby, 1·4 in Newcastle-on-Tyne, and 2·9 in Liverpool. The 40 deaths from diphtheria included 12 in London, 11 in Glasgow, 3 in Edinburgh, 2 in Dublin, 2 in Liverpool, and 2 in Halifax. Small-pox caused 4 deaths in London and its outer ring of suburban districts, 2 in Newcastle-on-Tyne, and 1 in Wolverhampton.

A Slighted Disinfectant.

A CONTRIBUTION to the current number of the *Gentleman's Magazine* calls attention to an old-fashioned disinfectant which has unaccountably fallen into disuse. The question of the value of sulphur as a disinfectant was revived by M. d'Abadie, who read a paper before the Paris Academy of Medicine on "Marsh Fevers." He stated that in the dangerous regions of African river mouths immunity from such fevers is often secured by sulphur fumigations on the naked body. Also that the Sicilian workers in low ground sulphur mines suffer much less than the rest of the surrounding population from intermittent fevers. M. Fouque has shown that Zephyria (on the volcanic island of Milo or Melos, the most westerly of the Cyclades), which had a population of 40,000 when it was the centre of sulphur-mining operations, became nearly depopulated by marsh fever when the sulphur-mining was moved

farther east, and the emanations prevented by a mountain from reaching the town. Other similar cases were stated. It is well understood by chemists that bleaching agents are usually good disinfectants; that which can so disturb an organic compound as to destroy its colour, is capable of either arresting or completing the decompositions that produce vile odours and nourish the organic germs of ferments which usually accompany, or, as some affirm, cause them. Sulphurous acid is, next to hypochlorous acid, one of the most effective bleaching agents within easy reach. Chlorine and hypochlorous acid (which is still more effective than chlorine itself), act in the opposite way, so do the permanganates, such as Condy's fluid, &c. They supply oxygen in the presence of water. It is curious that opposite actions should produce like results. These disinfectants are, however, objectionable on account of their odours and their corrosive action on metals; but the desired end may be attained without these annoyances. Sulphate of copper, which is not patented or "brought out" by a limited company, may be bought at its fair retail value of 6d., or less, per pound (the oil-shop name for it is "blue vitriol"), in crystals, readily soluble in water. By simply mopping the floor with a solution of these green crystals, and allowing it to soak well into the pores of the wood, they cease to become a habitat for specific poisons. The solution of sulphate should not be put into iron or zinc vessels, as it rapidly corrodes them, and deposits a non-adherent film of copper. It will even disintegrate common earthenware by penetrating the glaze, and crystallising within the pores of the ware, but this is a work of time (weeks or months). Stoneware resists this, and wooden buckets may be used safely.

Nickel Money.

MUCH has been said on the subject of putting into circulation nickel money, but the authorities are not so decided in favour of the proposition as they are thought to be. However, some pieces have been struck at the Paris Mint for specimens. To avoid their being mixed with silver, they are made of an oval shape; their value, it is said, is 5, 10, and 20 centimes. It is reported that the Minister of Finance will present these specimens for inspection at the Commission held in connection with the Budget, and if this body are favourable to the movement, steps will be taken to substitute in a given time nickel money for bronze. As New Caledonia abounds in mines of this metal this will be a good opportunity for the use of this production of the French colony.

The Royal Medical Benevolent College.

WE are asked to impress upon those of our readers who are Governors of the Royal Medical Benevolent College the fact that, owing to there not being a legal quorum present at the extraordinary general meeting of Governors convened on the 20th ult., the meeting was unfortunately obliged to be adjourned to the 10th inst., Wednesday (this day week), at four o'clock precisely. It is hoped that this will not again occur, as the proposed alterations to be made in the by-laws are of a very important nature in more ways than one, and it does appear a little hard upon the Council, who, having bestowed much time and care upon the question of

the good government of the College, find their labour in vain, consequent upon the apathy or lack of interest in its affairs on the part of the general body of Governors.

Hot Pack in Puerperal Eclampsia.

DR. BRENS expresses the opinion in the *Arch. f. Gyn.* that for the cure of puerperal eclampsia either in the puerperium or the last months of pregnancy, active diaphoresis alone, induced by a hot bath, 40 to 45°C, followed by the pack, is all sufficient. The bath must not be prolonged over one-half hour, and two to three hours suffices for the envelopment in the pack. This method properly carried out, according to Brens, will also cause œdema and albuminuria to disappear without interruption of pregnancy.

DR. WILLIAM KEARNS TANNER died on the 21st ult., at Lapp's Island, Cork, aged 71. Deceased was a graduate in medicine of the University of Glasgow, and a Fellow of the Royal College of Surgeons in Ireland.

A MADRID telegram states, on the authority of the Spanish Consul at Suez, that twenty-one pilgrims have died of cholera on the road between Mecca and Medina, and that there are daily ten deaths from the same epidemic at Medina.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 32; Bombay 26, Madras 33; Paris 27; Geneva 17; Brussels 22; Amsterdam 26; Rotterdam 29; The Hague 32; Copenhagen 20; Stockholm 32; Christiania 17; St. Petersburg 36; Berlin 23; Hamburg 24; Dresden 29, Breslau 26, Munich 27, Vienna 27, Prague 28, Buda-Pesth 24, Trieste 29; Rome 21; Turin 26, Venice 32; New York 22, Brooklyn 21, Philadelphia 21, and Baltimore 32.

WE understand that the Professors of Anatomy in the Royal College of Surgeons in Ireland (Professors Thornley Stoker and Cunningham) have taken advantage of the severe weather which we have lately had, and made a large number of sections of the frozen human body. Collecting a large quantity of snow, they subjected three bodies to the freezing process, and from these they have obtained nearly 150 sections of different regions. These will no doubt prove a very valuable addition to the teaching specimens of the school.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

GLASGOW.—ANDERSON'S COLLEGE.—The desired move westwards of Anderson's College, especially on the part of the medical teachers, received somewhat of a check at a meeting of the trustees held on the 22nd ult., when the Committee's report on the proposed removal of the Medical School to the vicinity of the University was presented. This stated that the funds at the disposal of the trustees did not admit of their purchasing a site and erecting a new school. The whole available funds of the institution

amounted to £13,000, and for the past few years the expenditure had exceeded the income by £200. Under these circumstances, the Committee were of opinion that it would be injudicious to take any steps to remove the Medical School unless £10,000 could be placed at the disposal of the trustees. The chairman, in moving the adoption of the report, remarked that the trustees were anxious to restore the School of Medicine to its former state of prosperity, but that they had not the necessary funds. An amendment was made by Dr. M'Kinlay, who characterised the report as very disappointing, urged that the present buildings should be sold, and a new college erected in the neighbourhood of the Western Infirmary. The amendment, not being seconded, fell through, and the report was almost unanimously adopted.

THE OUTBREAK OF TYPHUS FEVER IN EDINBURGH.—The prompt action taken by the medical officer of health has been effectual in checking the outbreak of typhus fever which was recently reported to have broken out in Buchanan Street, Leith Walk, and the fever has now entirely disappeared. In two tenements there were sixteen cases, two of which resulted fatally, and from the houses which were most in want of cleansing the families were, with the consent of their medical attendants, removed, and their houses cleansed at the expense of the corporation. In this way, and by the isolation of other cases, the spread of the disease was checked.

THE DEATH-RATE.—The Registrar-General's returns for the week ending with Saturday, the 23rd, show a great contrast in the respective death-rates of Edinburgh and Glasgow. The rate in the former is 21 per 1,000 per annum, and in the latter no less than 37. The average for the chief towns is 28.

GLASGOW MAGDALENE INSTITUTION.—The twenty-third annual meeting of the subscribers to the Glasgow Magdalene Institution was held on the 22nd ult. The directors' report showed that during the year the cases of 365 young women had been dealt with, and 157 were still under treatment, while 98 had been disposed of satisfactorily. The gross outlay for each inmate was £23 2s. 1d., but of that her earnings paid £15 7s. 10½., so that the actual cost per head was £7 14s. 3d. It appeared from the financial statement that the sum received for work was £3,546, that the legacies, &c., amounted to £2,241 16s. 8d., and the subscriptions to £1,031, and that there was still a burden of £2,500 resting on the institution. Dr. J. A. Campbell, M.P., remarked that, in connection with the institution, there were two subjects for thankfulness. The one was that, for any poor creature wishful to escape from a life of shame, there was a suitable asylum opened, and the other was that something like the results one would wish to see were realised. It seemed to him that the merits of the institution were very much owing to the great personal interest taken in all the arrangements by the directors and by a committee of ladies. The report was adopted, and the institution commended to public support.

THE EDINBURGH MEDICAL SCHOOL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am well aware that one of the most important duties of a medical journal is to criticise the teaching and examining qualities of the various universities and schools of medicine; but it must pain all lovers of fair criticism to read the remarks on the Edinburgh Medical School in your issue of December 27th. I have been a student in Edinburgh for five and a-half years, and have never observed the cringing attitude which you say the College of Surgeons

exhibits towards the University. As to the "boy-professors," I cannot see that the University is to be blamed for their appointment, if, indeed, as I much doubt, the appointments be blamable. As to your remark that high honours at the University may be gained by any good shorthand writer with a good memory, let me state as a first-class honours man myself that I do not know any honours graduate who is a good shorthand writer, and I do know several shorthand writers who have repeatedly failed to pass. I am quite willing to grant, what is I think unavoidable, that a man has a very much better chance of a medal if he state that which his professor believes to be true than the opposite. Your word "crotchet" is scarcely permissible as applied to the outcome of laborious work by an Edinburgh Professor. It is inevitable that in Prof. Fraser's class of Practical Materia Medica less dispensing will be done than where prescriptions for actual patients are made up, but the teaching is accurate and work carefully supervised.

Yours, &c.,

G. ARMSTRONG ATKINSON, M.B., C.M.,
Resident Physician, Edinburgh Royal Infirmary.

Dec. 30th, 1882.

contributor to the tales and tit-bits of a winter's fireside. . . . An examination of the Pharmacopœia from the geographical standpoint will enlarge a pupil's mind as well as give him knowledge valuable in pharmacy. A few pen-and-ink skeleton maps are easily and quickly drawn, on which may be written, by the student himself, in different coloured inks, the habitats of the minerals and plants yielding officially recognised drugs. These habitats he should himself search out from works on materia medica."

One golden rule Professor Atfield lays down, that these summaries, to be of any value, must be made by the student for himself, and exclusively by himself; and he enforces, what experience has shown ourselves, viz., that no student who is the friend of another student will even lend him his "notes." The improving part of note-taking and summary-making is going over and over again the notes, and the correcting, extending, and expanding of them. When the student has perfected his *catalogue raisonné*, and crowned the work by a therapeutical index, he realises that he has mastered the subject, and that he has nothing more to do than to keep abreast with modern progress.

While agreeing with every word of this admirable address, we cannot avoid expressing our surprise that the recommendation to students to study pharmacy in this particular way has not been made before; and yet an examination of the indexes of the *Pharmaceutical Journal* would appear to show that it is now made for the first time. We heartily commend this *brochure* to our readers, and wish that it were in the hands of every student.

Literature.

THE PHARMACOPŒIA AS A STUDENTS' MANUAL. (a)

ANY pronouncement upon his own department by the author of what is decidedly the best Handbook of Chemistry in the English language will command attention; and we have read this Address, which has been printed at the request of the students, with much interest. Professor Atfield truly observes that the Pharmacopœia is a book intended rather for the medical or pharmaceutical practitioner than for the student, and that to alter it into an educational manual "would involve the conversion of a single handy-book into a work of many volumes, amongst whose multitudinous pages all that relates to the practical manufacture or administration of medicines would be dwarfed if not hidden altogether. To adopt the plan partially and pithily would involve the giving of high official sanction to that too rapid and superficial acquirement of information still, alas! too common, though now everywhere deprecated."

The author, however, is of opinion that the pharmaceutical student should make the Pharmacopœia the basis of his education, by making for himself a *catalogue raisonné* of its contents, according as he progresses in chemistry, botany, and the other sciences upon which pharmacy is based. The nature of this index could not be better described than in the author's own words:—

"Sooner or later the pharmaceutical apprentice who means to be something more than a mere mechanical mixer of drugs, and not a mere hand-to-mouth vendor of drugs and sundries, will have himself prepared the following manuscripts:—First, a well-arranged list of the chemical substances mentioned in the Pharmacopœia, an improved form of his first rough catalogue of mineral preparations. Secondly, a similarly well-arranged list of the vegetable products, with, perhaps, added columns showing the botanical name of the plant, its common name, the part employed, the country whence obtained, &c. Thirdly, a complete list of the compounded drugs or mixtures, with added columns showing the names of their chief or more powerful components, and the proportions in which the active agents occur in the respective preparations, &c. The compounds might be subdivided into powders, pills, ointments, &c. . . . And if he extends his labours, as he probably will, to the generic and specific names of wayside flowers, he will go far towards fitting himself to be a charming companion for a summer ramble, a strong link in the conversational chain encircling the dinner table, and a valued

Correspondence.

PERNICIOUS ANÆMIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—An instructive case is recorded to-day in your valuable journal under the head of "Pernicious Anæmia." The patient—an inmate of the York County Hospital—had suffered for six months prior to admission from severe epigastric pain which kept him awake at night, and for a third of the time he had vomited after meals. The case was, in the first instance, diagnosed as one of malignant disease, though there was no tumour nor enlargement of any of the organs. He was, however, anæmic and emaciated. Under a course of treatment consisting of morphia, creosote, and nux vomica, supplemented subsequently by iron, quinine, and cod-liver oil, the patient recovered.

I had once a somewhat similar case under my care in India. Dr. A., a medical officer, æt. 49, was for several weeks troubled with incessant vomiting, accompanied by epigastric uneasiness—sometimes amounting to pain—after meals. He became very thin and anæmic, and certainly looked as if he were the victim of scirrhus of the pylorus, which, indeed, he himself believed. But he was a singularly irritable person, indulging to the full an Englishman's right (?) to grumble, and he availed himself of every opportunity to air his supposed grievances. His *élan* was quite startling. Listening with apparent composure to a companion, he would half-spring, in a Jack-in-the-box sort of way, from his chair, and exclaim, with an energy not at all called for by the occasion, "Exactly so!" and then subside into seeming apathy. His (constitutionally) nervous irritability was extreme; and, as I subsequently ascertained, whenever—being out of sorts—this became fully developed, it would centre in his stomach, which, after long residence in India, had become his weak point. About the time to which I refer, Dr. A. had been very much harassed, professionally and otherwise, and had intensified his troubles by his own impatience. His appetite became capricious and morbid, and he took his meals most irregularly. The vomiting, as I pointed out to him, occurred too soon after eating to justify the idea of malignant disease at the distal end of the stomach; and living in a malarious atmosphere in Lower Bengal was quite enough to account for his sallow and cachectic appearance. I felt sure that it was only necessary to soothe the nervous system generally, and that of the stomach in particular, which was accordingly done by a combination of opium and hydrocyanic acid, followed by tonics; and as about the same time he was relieved of all professional and other anxieties by retirement from the

(a) "The Pharmacopœia as a Students' Manual: being an Introductory Address delivered before the Students' Association of the School of Pharmacy of the Pharmaceutical Society of Great Britain." By Professor Atfield, Ph.D., F.R.S., &c.

service, recovery rapidly followed. When I last saw Dr. A., three years ago, he was in excellent health, with a remarkably clear complexion, and very unlike a man who had been twenty years in India.

I have thus given the particulars of this case as, in conjunction with that in the York County Hospital, it may—I say it with all diffidence—help to throw some light upon the true pathology of so-called pernicious or malignant anæmia, which, it is said in text-books, cannot be traced to any known causes, is steadily progressive, and generally fatal. Associated as it usually is with gastric derangement, and sometimes with general hæmorrhages or erratic attacks of fever—it is met with (says Roberts) chiefly in middle-aged pregnant women—may not the root of the disorder lie in some weak and irritable condition of the nervous system, by soothing and strengthening which the appetite becomes healthy, the food retained, and the anæmia disappears? The success of the treatment in the York County Hospital, and in the case under my own care, seems to justify this idea. If there be any truth in it, the prognosis might be more favourable.

Yours, &c.,

CHAS. R. FRANCIS, M.B., &c.

Clapham Common, S.W.,
December 20th, 1882.

PASS LISTS.

University of London.—The following candidates were successful at the recent B.S. examination for honours in Surgery:—

FIRST CLASS.

Walter, Fredk. Rufenacht { *Scholarship and* } St. Thomas's Hospital.
 Gold Medal }
Sutton, Samuel Walter (*Gold Medal*), St. Thomas's Hospital.

SECOND CLASS.

Scharlieb, Mary Ann Dacomb, Lond. Sch. Med. & R. Free Hosp.
Buxton, Dudley Wilmot, University College.

University of Dublin.—The following is a list of the successful candidates for degrees at the December examinations of this University:—

BACHELOR IN SURGERY.—William Hallaran Bennett, Joseph Bulfin, William Alex. Carte, Francis Richard Cassidy, Arthur Wellington Fenton, J. hn William Gowland, George Marshall Lloyd-Arj hn, Francis Albert de Thierry Monlliot, Henry William P. ard, Angus Mayberry Whitestone.

BACHELOR IN MEDICINE.—John Armstrong, Francis Richard Cassidy, Eugene Cormac, Richard Geo. Hanley, Arthur Wellington Fenton, John Fitzgerald, Dionysius William Freeman.

MASTER IN SURGERY.—Charles Gorman.

DOCTOR IN MEDICINE.—Charles Gorman, Edward Gordon Hull.

LICENTIATE IN MEDICINE.—Joseph Patrick Finegan.

LICENTIATE IN SURGERY.—Joseph Patrick Finegan.

Royal College of Surgeons in Ireland.—At the December examinations of this College the undermentioned candidates obtained the diploma in Surgery (L.R.C.S.I.):—

Arthur Cottew, Michael Cleary, Tho. B. Clune, Walter W. S. Corry, John Craig, Francis J. Cruise, Cornelius Dalr, Michael O'F. Dolphin, Percy J. Drought, James E. Fitzgibbon, John W. Gormley, Francis B. Hawes, George B. Heffernan, David W. Kennedy, Richard T. King, Thomas Lane, Edward E. Lennon, John J. Lyons, Hercules S. Miles, Hy. J. O'Brien, Denis M. O'Callaghan, John J. O'Hagan, Peter J. O'Reilly, Francis F. Peet, Francis E. Pim, Alfred E. W. Ramsbotham, George P. Ridley, James D. Ryan, George P. Turney, George A. Walpole, William H. Waterfield, Herbert Wright.

South London School of Pharmacy.—The following are the successful competitors at the examinations held last week at this school:—Senior Chemistry: no prize awarded. Junior Chemistry: Mr. Parker (medal), and Mr. Oldershaw (certificate). Botany: Messrs. Pridmore (medal) and Harvey (certificate). Materia Medica: Messrs. Armstrong (medal) and Oldershaw (certificate). Pharmacy: Messrs. Oldershaw (medal) and Johnson (certificate). Extra certificates were gained by Messrs. Burton, Horsfield, Hurcombe, Austin, Arnott, and W. Kinson.

Notices to Correspondents.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber,"

"Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 25 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clear, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

DR. WILSON.—Our correspondent in Paris writes us that the epidemic of typhoid may now be said to have fairly passed away. There are still a few fresh cases occurring daily, but these are of a milder type, and in the majority of cases do not prove fatal. You may therefore satisfy your patient that there is little fear on this point in Paris at the present time.

DR. CLIPPINGDALE'S paper, "On the Treatment of Hip-joint Disease," will be continued in our next.

MR. R. (London).—Sorry we are unable to accede to your request in our present number, but hope to do so in our next.

DR. MILLS.—The temperature is fairly equable in winter at the place mentioned; but we would advise you rather to send your patient to Bournemouth or to Hastings. If a sheltered position can be secured in the old part of the latter town, we consider it the most desirable health resort for winter in the United Kingdom.

AN INTENDING CANDIDATE FOR THE ARMY MEDICAL SERVICE will see an official notice in our advertising columns of the next examination for appointments in the Medical Department of Her Majesty's Army. The date fixed is February 19th, and following days, but applications must be made in due form at least fourteen days prior to this.

A. M. D.—There were four physicians in attendance throughout the illness, and all of them were agreed as to the pressing need for operative interference before the aid of a surgeon was called. The facts could not, for many and obvious reasons, be announced.

K.—Apply to Messrs. Burroughs and Wellcome; they will supply a sample if requested.

BICEPS.—When the Registrarship is vacant you will have the refusal of it, but, until then, you have no remedy. The Lord-Lieutenant may have a technical right to sanction such appointments, but the Registrar-General in reality selects the officer when there is any selection.

DR. CUTHBERTSON.—We cannot give you any information on the subject.

MR. JAMIESON.—The number of students who were present was not given. The result is incontestable.

DR. O. F.—There is nothing to be said in defence of such a practice. We cannot, however, take the matter up until it has been investigated by the police authorities.

A. R. L.—The writer of the article is at present away from London. On his return your note shall be submitted to him.

MASURBATION—A REMEDY WANTED.

To the Editor of the MEDICAL PRESS and CIRCULAR.

SIR,—I have a patient addicted to self-pollution. His mind is now impaired from the habit. I have tried various means to prevent it—blistering the penis, mechanical appliances, bromide of potash, &c.; but he still continues it. Could you or any of your readers suggest a remedy? Your obedient servant,

J. D.

[Potassium bromide is useless for your patient, as is shown by the recent work of Dr. Bartholow "On Spermatorrhœa" (p. 90), which we recommend you to read. Blistering is also useless; and we would recommend you to get your patient to swab the genitals with cold water at bed-time, and to wear an elastic cotton drawers (such as is used for bathing) at night. $\text{m} \times \text{v}$. doses of tinct. of ferric chloride with $\text{m} \times \text{v}$. of tinct. of nux vomica three times a day will be beneficial; also light bed-covering. If he be of sound mind, enjoin the most absolute chastity of idea; if his mind be seriously impaired you must have recourse to the apparatus contrived for preventing self-pollution in the insane.—ED.]

MR. M. M.—The lines are of good average merit, and suitable to the season, but hardly so to our columns.

ONE INTERESTED.—The Army Medical Inquiry is being carried on, though not rapidly; during the past week the Committee took evidence from a sergeant, corporal, and two privates of the Royal Artillery, each belonging to different batteries during the Egyptian war.

SECUNDUM ARTEM—Litholapaxy was introduced first by an American surgeon, Dr. Bigelow, who demonstrated his method in this country at a meeting of the British Medical Association a few years since. It has now become a well-recognized operation, Sir Henry Thompson having adopted it with the most successful results. You are quite right in your conjecture, but we do not wish to publish it any further.

ATTENDANCE ON SERVANTS.—"Senex" writes: Having recently received a "red ticket" to attend the servant (a housemaid) of a gentleman residing in my dispensary district, I would ask your opinion as to whether I cannot legally have said ticket cancelled. I should state, *in limine*, that I am not the attendant to the gentleman's family. My reasons for holding as I do that the ticket was illegally issued are: I have been informed, that, at "common law," a master stands *in loco parentis* to his household servants, placing the latter, consequently, outside the category of "poor persons." And by statute 23 and 24 Vic., c. 83, if a servant be admitted to a workhouse or infirmary "the master or mistress" is bound to contribute to his or her support during residence therein, showing also, I should say, that the

law does not look upon servants as paupers. Perhaps, Sir, the question might be worthy the attention of the Irish Medical Association, which has done so much for us heretofore, as it is somewhat annoying and unfair to be called upon to attend gratuitously a servant whose master does not consider the medical man good enough for himself.

[We have looked into the matter, and find the law stated in the following passage from Greenwood's "Laws Affecting Medical Men":—"A master is not bound to provide medical assistance for his servant, but the obligation (if any) must arise from contract; nor will such contract be implied simply because the servant is living under the master's roof; nor because the illness of the servant has arisen from an accident met with in the master's service." If, therefore, a master directs a practitioner to attend his servant, he must pay the practitioner; but if the servant calls for the doctor, or if the attendance be on dispensary ticket, no fee can be recovered.—ED.]

UNQUALIFIED PRESCRIBING CHEMISTS.—"Medicus" asks: 1. What are the means by virtue of which a man can keep open shop for sale and compounding of medicines? 2. Can a man who has no qualification be a proprietor provided he keeps a qualified apothecary or pharmaceutical chemist? 3. Is there no Council or Society to prevent and punish those men possessing no qualification whatever from keeping open shop, compounding prescriptions, even visiting, prescribing, and passing off as the "doctor"—sometimes going so far as to perform dental and surgical operations? 4. Can boards of guardians, governors of Government Institutions legally allow an unqualified man to do the duties of a qualified person? and what steps should be taken to put a stop to such a disgraceful thing, which I know is permitted?

[1. An open shop for compounding medicines may be kept by—persons qualified under (a) Apothecaries' Act, 31 Geo. III., cap. 34; (b) Pharmacy Act, 38 and 39 Vic., cap. 67; (c) Medical Act, 21 and 22 Vic., cap. 90, sec. 31. 2. Will be answered next week. 3. Under 30th sec. of Pharmacy Act, the Council of the Pharmaceutical Society can prosecute an unqualified person who keeps open shop. No person can be prosecuted for acting as a medical practitioner, but only for publicly representing himself to be a qualified practitioner. 4. Under sec. 34 of Medical Act, no unqualified person can hold any office in a workhouse or union, nor sign any certificate. If proof of such person having done so be submitted to the Local Government Board they will probably put a stop to the proceeding.—ED.]

CORONER'S QUALIFICATION.—"A Constant Reader" asks:—What are the qualifications of a coroner? Is there any property qualification?

[The Acts of Parliament regulating the office of Coroner are the 9th and 10th Vic., cap. 37, and the amending Act of 1831, 44th and 45th Vic., cap. 35, which will be found in the "Irish Medical Directory." By the Act of 1831 it is provided that no one shall hold a Coronership unless he—(a) is duly qualified to practise Medicine or Surgery, and registered as such under the Medical Act; or (b) is a Barrister-at-Law; or (c) is a Solicitor; or (d) is a J.P. of five years' standing. The property qualification is abolished.—ED.]

APPOINTMENT OF LOCAL GOVERNMENT INSPECTOR.—"Navy Surgeon" asks:—1. How the appointment of Irish Local Government Inspector is obtained? 2. If those appointed must have served a specified time as Poor-law Medical Officers? 3. If there is an examination to pass, and if such is competitive?

[1. The appointment is made by the Local Government Board, subject to the approval of the Lord Lieutenant, under sec. 3 of Medical Charities Act (14 and 15 Vic., cap. 63), and sec. 5 of Poor Relief Act, 19 and 11 Vic., cap. 90. (See *Irish Medical Directory*, page 512 and 521.) 2. Any person, with or without medical knowledge or experience, may be appointed. 3. No examination.—ED.]

WHAT ARE ZENANA MISSIONS?—As we are not unfrequently asked for information about "Zenanas" as related to medical missions abroad, the following, from the December number of the *Sunday at Home*, will be read with interest:—"We Zenana Missionaries often talk over and get hints from one another as to the best way of introducing 'The Light of Truth' into these dark homes. It is by no means always to be done in the same way in every place and in every house. Sometimes our friends wish to learn reading, then, of course, we can choose our books. Sometimes they wish to learn work, which gives us a reason for going regularly to them, and having a chat or reading a portion of Scripture. Sometimes they only wish for conversational visits. Then it is a little difficult, without abruptness, to give the tone we wish to our intercourse. As a rule, in a first visit we do not attempt more than a few kindly words and inquiries; but conversation is apt to flag, and to-day my zenana-bag helped, as it has done on other occasions, to fill up a gap. It is a conspicuous bag, with a cleverly-embroidered bird outside. Thus it often attracts the attention I wish it to receive. I am much indebted to the unknown friend who at some working party for the zenana mission added 'those crimson to the quaint macaw.' To-day he was admired and handled. Then some curiosity was evinced regarding the contents of the bag so decorated. Out came photos of the Queen and other members of the Royal Family. They were interested in hearing about the Empress-mother and her children and grandchildren. Then a book of beautifully-coloured Bible pictures attracted their attention. I pointed to one of the Prodigal Son, and asked if I should tell them about it, to which proposal they gladly assented. I had learnt the parable off by heart from the *Hindustani Testament*, and an attentive audience, increased by one or two female servants, and some schoolboys of ten or twelve years old, gathered round. Thus a part of the 'old, old story' was once more told in ears which had not before heard it. The result is with God."

A DISPENSARY TORMENT OF MINE.

THERE'S a patient for ever complaining and sick,
And he's never quite free from the dolorous tic,
Groaning on,—groaning on,—by no treatment made well,
That was not the patient whose story I tell.
But the invalid never obliged to remain
Confined to his bed, there alone to complain;
Still coming and going his doctor to worry,
And seeming as though he was ne'er in a hurry.
When middling he looked as though out of the sphere,
That Nature intended to place him in here;
And when sick, oh, my goodness! the doctor was paezed
To try all his cures but the good one of rest.
For he wanted some quinine, black draught, and blue pill,
Some tincture of ginger, and essence of dill,
Paregoric elixir, and lactate of zinc,
And syrup of phosphates in gallons he'd drink.
If calomel touched him he'd spit for a week,
And potassium iodide would quickly seek;
If taraxacum failed to relieve him of bile,
He'd seek for some comfort in pure castor-oil.
Then when coughing you'd think he'd a frog in his throat,
And he'd tear through the neck of his shirt and his coat;
For he'd take hippo wine and confection of rose
That would act on his stomach as well as his nose.
If his skin should feel rough he'd have sarasaparilla;
If his sleep went astray he'd put hops in his pillow;
If his appetite failed he'd try gentian and salts,
Or a mixture of Evans' and Jamieson's malts.
But what was his illness no mortal could say,
And I'm sure they'll not know till its nearly domesday.
Should Providence take him from this world of care,
I'd say "Deo gratias" in most earnest prayer. J. P. E.

MEETINGS OF THE SOCIETIES.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—Wednesday, Jan. 3rd, at 7.15 p.m., Council Meeting.—8 p.m. Mr. Percival Gordon Smith, "On the Planning and Arrangement of Hospitals for Infectious Disease."
HARVEIAN SOCIETY OF LONDON.—Thursday, Jan. 4th, at 8.30 p.m., Dr. Morton, "On a Successful Case of Ruptured Perineum."—Mr. Noble Smith, "On Lateral Curvature of the Spine" (with specimens).
ROYAL INSTITUTION.—Saturday, January 6th, at 3 p.m., Professor Tyndall, "On Light and the Eye."
ROYAL INSTITUTION.—Tuesday, Jan. 9th, at 3 p.m., Professor Tyndall, "On Light and the Eye."

Bacancies.

Chorlton Union.—Assistant to the Resident Medical Officer. Salary, £120, with furnished apartments, &c. Applications to be sent to the Clerk to the Guardians not later than Jan. 24th.
General Infirmary, Northampton.—House Surgeon. Salary, £125, with furnished apartments, &c. Applications to be sent to the Secretary on or before Jan. 8th.
Gorey Union.—Medical Officer. Salary, £100, and £20 as Consulting Sanitary Officer. Election, Jan. 6th.
Kilkeel Union.—Medical Officer for Workhouse and Fever Hospital. Salary, £50. Election, Jan. 8th.
Kilkeel Union, Kilkeel Dispensary.—Medical Officer. Salary, £100, and Vaccination Fees. Election, Jan. 6th.

Births.

ANDERSON.—Dec. 21st, at Newtownhamilton, the wife of W. W. Anderson M.D., of a son.
M'DONAGH.—Dec. 29th, at Mornington Villa, Hampstead Road, London, the wife of James S. M'Donagh, M.R.C.S., of a son.

Marriages.

ROBIN—POLLOCK.—Dec. 25th, the Rev. Percival Carteret Robin, to Fanny Margaret, second daughter of James E. Pollock, M.D., of 62 Upper Brook Street, Grosvenor Square, London.

Deaths.

FAWSETT.—Dec. 18th, at Wisbech, Frederick Fawsett, F.R.C.S., aged 76.
HART.—Dec. 27th, at 32 Great Coram Street, London, W.C., Adolphus Daniel Hart, M.R.C.S., aged 49.
HEWSON.—Dec. 21st, at Park Villas, Haipurhey, Manchester, Sydney Hewson, M.R.C.S., aged 55.
IRWIN.—Dec. 19th, of typhus fever, at Ivy Lodge, Kilkeel, Fitzjohn Robert Irwin, M.B.
LOYD.—Dec. 11th, at Tyn Rhyll, Rhyl, Edward Lloyd, M.D., L.R.C.P., formerly of Castella, Glamorgan, aged 62.
MACLEAN.—Dec. 19th, at the Royal Victoria Hospital, Netley, Surgeon-Major J. McK. MacLean, Army Medical Department.
PATERSON.—Dec. 9th, suddenly, at Bahia, Brazil, John Lijertwood Paterson, M.A., M.D., of Edinburgh, aged 62.
RUGG.—Dec. 26th, at Chichester, Richard Rugg, F.R.C.S.E., formerly of Brighton, aged 75.
SHEPHERD.—Dec. 12th, at Beach Cottage, Teignmouth, Fleet-Surgeon Charles Douglas Shepherd, R.N., aged 61.
TANNER.—Dec. 21st, at his residence, Lapps Island, Cork, William Kearns Tanner, M.D., F.R.C.S.I., aged 71.
WEST.—Dec. 17th, at Cairo, Edward de Lancy West, M.B., C.M. Edin., of Epsom, aged 28.

QUINQUININE (MACKEY'S) Registered.

Takes the place of Quinine at considerably less price. Every genuine bottle has the name Mackey, Mackey, & Co. Therapeutically Mackey's Quinquinine equals Sulphate of Quinine.—THOS. HORSER, L.R.C.P., Sandwich. Price, in 1 oz. vials, 6s.

MISTURA CERII COMP. (MACKEY'S). By Royal Letters Patent.

Specific for Obstinate Vomiting of any Kind.

A SPECIFIC FOR VOMITING IN PREGNANCY, Sick Stomach, in alleviating the pain and vomiting in Carcinoma and general Chronic Vomiting and reliable remedy for the cure of Indigestion, &c. Dose 15 to 60 minims IN BOTTLES 5s. and 9s.
"The MISTURA CERII Co. is particularly successful in all cases of irritable stomach, dyspepsia, &c., and I HAVE FOUND IT ALLAY VOMITING (no matter the cause) WHEN ALL OTHER REMEDIES HAVE FAILED.—R. T. W. SMITH, F.R.C.S., &c.

MACKEY'S MIST. BISMUTHI COMP. Dr. Browning's. Registered. Tonic Digestive.

Dose 15 to 20 minims. The only reliable preparation of Bismuth. The *Lancet* says:—"Bismuth could hardly be given in a better form. I have used the Mistura Bismuthi Comp. prepared by Messrs. Mackey, Mackey, & Co., and have found it most EFFICACIOUS AND FAR SUPERIOR TO ANY OTHER PREPARATION OF BISMUTH THAT HAS COME UNDER MY NOTICE."—C. KATON BAKER, M.R.C.S., &c.

CAUTION.—The large demand for our specialities has caused systematic imitations. The Profession is earnestly requested, if not ordering direct, to give special prominence to the word **MACKEY'S** e.g. Mackey's Quinquinine; Mackey's Mist. Bismuthi Co.; Mackey's Chlorodyne, all soluble Compounds of Cerium, and improved preparations of the Hypophosphites.

MACKEY, MACKEY & CO. (Wholesale and Export Druggists and Manufacturing Chemists), 1 & 2 BOUVERIE ST., LONDON, E.C.

FRY'S  **MALTED** **COCOA** AND **CHOCOLATE**

Are COMBINATIONS OF FRY'S PURE COCOA EXTRACT and CHOCOLATE PASTE with ALLEN and HANBURY'S CONCENTRATED EXTRACT OF MALT, affording delicious beverages. The Extract may be most agreeably taken in either of these forms. Sold in tins at 1s. and 2s. each, 9s. and 18s. per dozen. The Cocoa is in the form of Powder, the CHOCOLATE of PASTE, and Sweetened.

THE LANCET, Dec. 18th, 1880:—"This is an excellent preparation of Cocoa and Malt Extract. It is dried at a gentle heat to avoid injury to the diastase; its dietetic and digestive value is beyond all dispute, and it is very agreeable in flavour."—See also *British Medical Jour.*, Nov. 13, 1880; *Med. Times and Gaz.*, Jan. 1, 1881; *Medical Press*, Jan. 26, 1881.

To be had of the Manufacturers, all Chemists and Wholesale Houses, or from

ALLEN & HANBURY'S, Plough Court, Lombard Street, London, E.C.

CONROY'S MALT COFFEE.

"As a breakfast beverage it is unsurpassed."—Dr. SANDERSON, M.R.C.S.

"A nourishing and health producing article of diet."—E. DAVIES, F.C.S., &c.

"Most beneficial in cases of atonic indigestion."—Dr. ADAM, M.R.C.S. Eng.

"I have frequently recommended CONROY'S MALT COFFEE in cases of weak digestion, invariably with satisfactory results."—W. BELL, M.R.C.S.

"I consider CONROY'S MALT COFFEE a most excellent combination, rendering it a luxury which should be found in every home."—A. W. POSTANS, F.C.S.

"CONROY'S MALT COFFEE is a wholesome and nutritive preparation, and one calculated to be of great use in cases of impaired digestion. In my own case I have found it palatable, and certainly an assistant to a weak digestion."—WM. DOROVAN, L.R.C.P., &c, Medical Officer of Health.

Contains about 75 per cent. PURE COFFEE. Malted by a patent process.

Consists solely of Coffee and Malt. Flavour equal to finest coffee.

Doctors recommend it. Contains all the valuable principles of Malt.

More nutritious than beer or porter. Causes no unpleasant eructations.

Promotes sound and healthy digestion.

Breakfast beverage par excellence.

It is made in the same way as ordinary Coffee.

Pamphlets containing testimonials from eminent scientific, medical, and other gentlemen of the highest positions, may be had free for gratuitous distribution.

Quotations in quantity on application. In cases of 56 lbs each, put up only in 1 lb. and ½ lb. tins. Each tin is protected by an Excise stamp under the regulations of the new Inland Revenue Bill of August 3, 1882.

Prepared only at the **MALT COFFEE WORKS, 34 FLEET STREET, LIVERPOOL.**

To be obtained from all Druggists and Grocers, and wholesale from the

Sole Proprietors **EVANS, SONS, & CO., 56 Hanover Street, Liverpool.** London: **EVANS, LESCHER, & WEBB, 60 Bartholomew Close, EC.**

Brand & Company TO **H.R.H. the Prince of Wales.**
(Established 1835.)

GENERAL PARALYSIS FROM CRANIAL INJURY.

By WILLIAM JULIUS MICKLE, M.D., M.R.C.P. Lond.

In the cases that have come under my own observation, where cranial injury has conducted to general paralysis, it has, in the majority, seemed to play the part of a predisposing, rather than of an exciting, cause. And yet, in some examples, this may be so in appearance only, and may not represent the actual course of events; for the injury may have left behind it not only a permanently damaged condition of encephalon, but also some obscure, insidious, and undetected inflammatory process about the brain surface and meninges, which, either with, or without, any augmentation of its activity and extent from the operation of some other exciting cause of the disease occurring later in time, and perhaps acting more directly, may have culminated in general paralysis.

From cranial injury may arise molecular perturbation of the cerebral tissue, or bruising, crushings, hæmorrhages, and even ruptures in the same, or in the meninges.

In speaking of cranial injury as a predisposing cause of general paralysis, we may suppose that, in consequence of latent residual results of the above-named hurtful immediate effects of trauma, either the cerebral tissues are simply less resistant to the influences of ordinary causes of the pathological process which underlies general paralysis, or that this process springs more fully into being by assisting in, and in its own turn being assisted by, the intensification and extension of slight local inflammation or hyperplasia sequential to the brain injury; or, again, assisted by morbid vaso-motor effects of that injury.

On the other hand, where cranial injury acts as an immediate exciting cause of the disease, it will do so by the direct development into the lesion of general paralysis, of secondary results of the molecular, or fine, or of

the gross, local damages already named, to which vaso-motor effects of the traumatism may or may not be contributory. For injury to produce this result the brain tissue must, perhaps, be ready to move, as it were, in the direction of general paralysis.

Usually, no doubt, several influences conduce to the occurrence of this and other mental diseases.

Cranial injury has appeared to be a factor in the production of general paralysis less frequently, in my experience, than in that of some observers. Sometimes it is doubtful whether the cranial injuries are in any way causal or not. Without entering into statistics, therefore, I will give a few brief extracts from notes on several hitherto unpublished cases, to which others might be added.

The following is an example of the sort of case, of which mention has been made, where injury was presumptively a predisponent:—

A. T., a sergeant, 77th Regiment, admitted March 10th, 1880, at the stated age of 29, but looking older; service in army, 57-12ths years. General paralysis had come on in an insidious manner more than a year before admission.

The patient, a fairly educated French Canadian, had for some time been a mercantile clerk at Paris. Serving in the cause of civilisation against the desperadoes of the Paris Commune, in 1871, he was struck by a partially spent rifle-ball on the head, close to the left parietal eminence, and lay insensible for several days. Subsequently entering the British army, his good conduct, temperate habits, fair education, general intelligence, and docility gained for him promotion as sergeant. Unfortunately, his promotion brought with it numerous worries and anxieties, and overwork in the orderly-room at Dublin. He became depressed, melancholy, and strange for several months—slovenly, forgetful of orders, and careless as to duties. Then, on June 20th, 1879, he was placed in hospital, under observation, until discharged on July 27th. But after this he still was strange, asked for whitewash for his tent-roof, got up in the night to wash the floor and clean belts, said he was going to the Curragh to shoot for a £40 cup, and was about to be

married, there being no real foundation for either statement. After this, tremor of lips, thickness and hesitation of speech, impaired deglutition, greedy eating, dirty and mischievous habits, defective memory, and confusion of ideas were noted.

On admission.—There was no history, acknowledgment, or sign of venereal disease. The speech, tongue, and face were moderately affected by the ataxy and paresis of general paralysis; but there was also incomplete left facial paralysis, especially of the lower part of the face, the upper part being little, if at all, affected; the left palate was also slightly palsied. The pupils were slightly irregular in shape, somewhat sluggish to light, and about equal in size. The gait was somewhat shaky, jerking, uncertain in sudden turning, and the heels were rather brought down; if in walking the eyes were closed, there was some staggering; the knee jerk was absent, and there was no ankle clonus.

Without transcribing the notes, it may be briefly stated that the patient was somewhat demented, childish in conversation, often restless, and of an anxious, worried facial expression; yet usually passing into a condition of self-satisfaction and gusto in describing what he had done and what he hoped to do, the latter embracing projects beyond his capacities. But during the less than three months' time he was under my care there were no obvious exalted, grandiose delusions (at least, none of extravagant form), or hallucinations, or epileptiform or apoplectiform attacks, or cephalæa, or knee jerk, except once slightly.

On June 4th, 1880, he died of an acute affection unconnected with the cerebro-spinal disease.

Abstract of necropsy.—Dura rather thickened, congested, slightly too adherent to calvaria at parts. Arachnoid and pia very thick, opaque, and pia œdematous, these meningeal changes being of unusually diffused distribution. Several atheromatous patches in basal arteries. Adhesion and decortication, only very slight, and found over the middle of the left second temporal gyrus and tip of left second frontal. Grey cortex of cerebrum pale in anterior regions, somewhat wasted over convexity of frontal, and less, of parietal lobes; slightly thinner in right anterior and middle regions. A slightly shrunken, withered appearance of posterior part of left nucleus caudatus. Ventricles of encephalon all highly granulated; lateral ventricles appearing relatively rather large. Pons and medulla oblongata firm. Cerebellum rather firm, free from adhesion and decortication. No gross lesion of cranial nerves at base of brain made note of. The posterior columns of the spinal cord were unduly firm from incipient sclerosis, and in the cervical region they turned of a reddish-grey colour after section and exposure to the air, but no local circumscribed patches could be made out. Of other results of the necropsy, perhaps it will suffice to mention some atheroma of left coronary artery and of aorta; very slight hepatic cirrhosis; slight traces of old adhesive perihepatitis; renal capsules slightly adherent.

In the next case the cranial injury seems to have been the exciting cause of general paralysis.

The patient was admitted in October, 1879, then aged 37; service in army 15 4-12ths years; of good conduct and temperate habits; had gonorrhœa and a venereal sore in 1868; in 1869 had "rheumatic" pains in hips, knees, legs, and wrists, but no swelling.

Having been beaten severely about the head with sticks by some military prisoners, he was admitted into hospital at Kandy, Ceylon, for surgical treatment, on August 20th, 1878, and, with the exception of three days, he there remained until the end of September, but was immediately readmitted. Discharged again, after forty-two days, he was not allowed his wish to go to the Zulu war. For some short time previously to this, his manner had been strange, and after this refusal he was depressed, and was admitted into hospital, at Colombo, for mental failure. Deep-seated cranial pains were suffered; vivid hallucinations were evinced. The Virgin and saints, he

said, visited him; angels blew on his head and healed the cracks in his skull; he saw and heard the Archangel Michael and others. With these was some emotional exaltation.

On admission (abstract).—When admitted, scars of the cranial injuries remained, especially about the left brow and temple. Speech somewhat hesitating and stumbling, with occasional repetition of syllables. Tongue fairly protruded, this movement being accompanied by some twitching of upper lip; forehead contracted from time to time, and brows raised. Pupils rather sluggish, and slightly irregular in outline. Handwriting rather irregular and shaky. No indications of syphilis. Said he had had severe pain in back and vertex of head for nine months after cranial injury; the pain wore away gradually.

Mentally, he was better, holding his former delusions apparently in doubt, and having no acknowledged present hallucinations. Ordered potassii iodid.; ammon. carb. In 1880, potass. iodid., and syr. ferri iodid.

Mental improvement occurred for a time, but seven months after admission, and later, he wrote letters giving expression to absurd, exalted delusions, such as that the Almighty visited him and made him carry a cross to save the world; that he was the Virgin; could stop the rain and bring it down; could redden the moon and brighten it again. The spelling, caligraphy, and composition pointed to general paralysis. Mentally, he became better, but, refusing the above medicines, was given hydrarg. perchlor. unknown to him. The motor signs of general paralysis became much lessened; the tactile sensibility was fair.

In 1881, delusions, as above, could be elicited at times. Body-weight higher than ever. The nape was blistered, and a discharge kept up for many months by antimonial ointment; the mercury was continued internally. The motor signs of general paralysis became very faint. No local palsies or epileptiform convulsions were observed. Treatment had kept the disease in check, and had assisted in procuring, at least, a decisive remission.

Another case, in which the cranial injury acted apparently as an immediate exciting cause, but in which there was a long syphilitic history, was that of a soldier who suffered a severe injury to the head in July, and on the 29th of that month was admitted into hospital with "maniacal" symptoms. Seven weeks afterwards he was discharged to duty, but was re-admitted in the January following with general paralysis, the true onset of which had probably been marked by the mental symptoms which followed closely upon the cranial injury. Later on he was admitted here. In the army he had been of good character and steady temperate habits; and there was no record of sunstroke, convulsion, or palsy; but there was a distinct history of syphilis incurred ten years previously.

Finally, brief mention may be made of a case in which an injury to the spine was one of the assigned causes of general paralysis that principally attracted the attention of the army surgeons; but there appeared to have been an injury to the head also, and part of this soldier's service had been abroad, and in unhealthy climates.

W. L., sergeant, Royal Artillery, admitted May, 1880, æt. 35, after eighteen years' service, mental disease having been very obvious from the preceding October, but apparently having been more or less existent for nearly four years, and the causes assigned for it being "long military service and injury to the spinal cord." The patient was temperate, of good conduct, and had no history of relatives affected with insanity or convulsions. It appears that in May, 1870, he was struck on the back and abdomen by "sheers" at Woolwich. (He stated that at the same time he was struck on the head as well, and explained a scar over the right parietal bone as being a result of that injury.) Supposed as a sequel to this accident, he was admitted into hospital at Halifax on April 16th, 1876, and for forty-one days, the entry on his "medical history sheet" being "injury to spinal cord." Subsequently, he was in feeble health, mentally changed, slovenly, neglectful

of duties and orders, depressed, discontented, making silly and unfounded charges against those about him. Stationed at Bermuda, he was admitted into hospital on Sept. 29th, 1879, and was, or became, restless, excited, irritable, sleepless, peevish, sulky, dull, with outbursts of rage, gave absurd and confused orders, was noisy, mischievous, destructive to clothing, and on one occasion rushed from hospital to the sergeants' mess and said he had put all those in hospital under arrest.

When here he had exalted delusions, co-existing with absurd delusions of ill-treatment, of being starved, of having, daily, frightful corporeal injuries inflicted, of his life being threatened, and attempts made to poison him. Though at times buoyant, he was usually sullen and morose, often threatening and full of invective. There were hallucinations of sight and hearing, and muscular illusions as to flight of body. Knee-jerk well marked. No ankle-clonus. Once, temporary left hemiparesis, and left facial paresis. Speech, moderately affected. Pupils, face, tongue, gait, considerably affected. No epileptiform seizures. The patient was subsequently transferred.

RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S. Eng., M.S. Lond]
Surgeon to the London Hospital.

PART II.—Reported Cases of Recovery—Treatment—Conclusion.

(Continued from page 3.)

WE now reach the reported cases of recovery after intra-peritoneal rupture of the bladder. Abstracts of six of the eight cases referred to will be found in Max Bartel's list—viz., those reported by Walter, Erskine Mason, Thorp, McDougall (2), and Chaldecott—and only one is admitted by that laborious and careful author as a genuine case of recovery after intra-peritoneal rupture. He disposes of four—viz., the cases of Thorp, Erskine Mason, and McDougall—by regarding them either as errors of observation or as cases of sub-peritoneal or extra-peritoneal rupture mistaken for intra-peritoneal. Chaldecott's case is passed over in silence. I will take Dr. Walter's (a) case first. A man, 26 years of age, in good health received a blow upon the lower part of the belly. He almost fainted, and complained of violent pain in the region of the bladder. Some hours later the belly had swelled, and became very tender, especially just above the pubes. The pulse was small and frequent, the skin cold, respiration hurried, and urination almost impossible. There were nausea and vomiting. The catheter withdrew a very little bloody urine without relief. Three grains of opium were given at once, and one grain every hour afterwards. The catheter was retained in the bladder. Ice was given in fragments for the patient to suck. No relief being thus produced it was decided to open the belly. Ten hours after the accident chloroform was given. An incision was made in the linea alba, commencing one inch below the umbilicus and terminating one inch above the pubes. The intestines were found distended with gas and the vessels beginning to be injected. A sponge introduced mopped out nearly a pint of urine and extravasated blood. A rent was observed in the base (?) of the bladder two inches long. As soon as the urine was evacuated the bladder was left to itself, and the abdominal wound was closed with pins retained by silver threads, care being taken not to involve the peritoneum. A flannel bandage was placed round the belly. On waking from chloroform the patient felt much relieved. The vomiting ceased. One grain of opium was ordered to be taken every hour, and the general treatment was the same as before. The night passed well, and the next day there was neither

pain nor desire to micturate. There was no tympanitis. A little iced water was allowed. The catheter gave exit to urine unmixed with blood. On the third day the quantity of opium was reduced. At the end of the first week the wound had united. During the third week the catheter was only used every four hours.

That the foregoing is a genuine case of recovery can scarcely be questioned, unless it is possible for an observer to mistake serous fluid and blood for urine and blood, and by an optical illusion to fancy that he sees a rent where none exists. It would, however, have been as well if a catheter had been passed into the bladder and through the rent after the abdomen was opened, so as to complete the demonstration, and leave no room for scepticism. Mr. Heath adopted this plan. Of the seven other cases of reported recovery after a presumed intra-peritoneal rupture, Mr. Le Gros Clerk's case is the only one which is not absolutely claimed by the author as a genuine instance of this happy termination. That case, as I have endeavoured to show, lacks the proof of the very essential primary condition for an intra-peritoneal rupture—distension of the bladder—and a careful examination of five of the others displays this deficiency in a greater or less degree. It is of little consequence, perhaps, which of these cases we investigate first, but I will take Dr. Henley Thorp's (a) case, because it has been elevated into a fictitious importance by the *imprimatur* of one of the leading surgeons of the day, Mr. Christopher Heath, and because Mr. Heath founds upon it a general recommendation for the treatment of cases yet to come. Dr. Thorp's preamble appears particularly inopportune, for, after regretting that "any want of precision or completeness in the details" of Mr. Chaldecott's case "should lead to doubts as to its real nature," and suggesting that Mr. Chaldecott was not "aware that the bladder is liable to give way in any other position than posteriorly," he makes this courageous assertion: "The following case, however, which has recently occurred in my practice, was seen by two other surgeons, and, watched throughout with great interest and anxiety, places the question beyond dispute." The revenge of time reversed the respective position of Mr. Chaldecott's and Dr. Thorp's cases, for in Mr. Birkett's excellent article, I find that he admits Mr. Chaldecott's as one of the three cases of recovery out of the fifty to which he refers, the symptoms being "those of extravasation of urine into the peritoneum," whilst, after stating in a foot-note that "possibly Dr. Thorp's case should be added to those of recovery," he adduces in the text the following cogent reasons against its pretensions:—"It is to be much regretted that only the local symptoms of the injury are fully detailed. We vainly search in the account of the first two days after the injury for those constitutional symptoms which are so constantly present after the occurrence. This omission is most unfortunate after the introductory observations which precede the recital of the case." The history is as follows:—A farmer, 30 years of age, intoxicated, was thrown from his horse. No account could be obtained from him as to the state of his bladder at the time of the accident, or as to any injury to the hypogastric region. He was found lying on the roadside, and when consciousness returned, he experienced a severe pain at the bottom of his belly, attended with an urgent desire to pass water, without the power of emptying his bladder. On visiting the patient four hours later, Dr. Thorp found him in a sitting posture, with his body bent forwards. He complained of an oppressive burning pain in the hypogastric region; there was pressing inclination, without the capacity, to micturate; the abdominal muscles, more especially the recti, were rigid and tense, and any attempt to stand upright produced a great increase of suffering. He had neither vomiting nor rigor, nor did the surface of the belly present any contusion or other mark of injury. A full-sized gum-elastic catheter entered the

(a) Ranking's Abstract, 1862, vol. II, and Philadelphia's Medical and Surgical Reporter. I have only been able to refer to Ranking's Abstract.

(a) Dublin Quarterly Journal, Vol. xvi., p. 306.

bladder without difficulty. At first no fluid escaped, but upon pushing the instrument onwards, and at the same time turning it a little upon its axis, about a tablespoonful of bloody urine flowed out. No further quantity coming away, I withdrew the catheter a short distance, twisted it round in another direction, and again passed it backwards, when an additional ounce of a reddish fluid welled over without force or jet. By changing the position of the patient from side to side, turning him over upon his knees, and substituting a silver for the gum-elastic instrument, I at length succeeded in obtaining nearly half a pint of urine mixed with blood. The patient expressed himself as much relieved. He was placed in a half-sitting posture, some laudanum administered, and a gum-elastic catheter was left in his bladder a few drops of clear urine distilling over." Even before he had introduced the catheter, Dr. Thorpe had jumped to the conclusion that there was a rupture of the bladder into the peritoneal cavity! "The diagnosis of the accident," he writes, "was exceedingly simple. The position of the patient in the sitting posture, with the body bent forward, the spastic rigidity of the abdominal muscles, and the urgent but unavailing efforts to pass water, enabled me to predicate the mischief before I introduced the catheter. Then the empty state of the organ, and the mode the bloody urine overflowed the instrument without impetus, in small quantities at a time, irregularly and interruptedly, uninfluenced by pressure above the pubes, but clearly affected by pushing the instrument backwards, changing its direction, turning it on its axis, &c., and also the postural expedients described, placed the nature of the case beyond the possibility of doubt. However, it is not every case of ruptured bladder that presents features so palpable and undisguised." Let it be remembered that this passage was written in the absence of any kind of evidence of a full bladder and direct injury to the hypogastric region, in the absence of symptoms of shock, and without accurate local examination of the abdomen or rectum. Anxiety of countenance, restlessness, constitutional depression, nausea and vomiting, distension of the abdomen and fluctuation, found in the less "palpable and disguised" cases, were conspicuous by their absence. A mere contusion, with loss of power over the bladder, and a laceration of the mucous membrane, or some other cause of obstruction, such as a false passage near the orifice of the bladder, would account for the symptoms. There is, however, a sequel which is particularly instructive. Dr. Thorp left his patient for a few hours. The patient did not sleep, and suffered from pain in the belly. The distressing desire to urinate passed off, drops of clear urine escaping at intervals from the catheter. Dr. Thorp returned provided with a half-pint elastic bottle and a stopcock. He withdrew the gum elastic catheter and introduced a silver instrument into the bladder. "The organ felt contracted, and did not easily admit of the complete introduction of the instrument; nor could the latter be depressed, pushed onwards, or moved about with the same ease as previously. Furthermore, the manipulation caused much pain, and accordingly the gum elastic catheter, now mounted upon a strong stilet shaped like a sound, was again passed into the bladder. Its movements likewise were at first restricted and painful, until after cautiously probing and turning its point it entered nearly its full length, when a different feeling of resistance was communicated, and it could be moved about with somewhat greater freedom. The stilet being withdrawn, a tablespoonful of reddish urine flowed away." Clearly, then, the catheter had not passed into the peritoneal cavity through a rent in the bladder. The limitation of movement and the small quantity of urine show that it was in a nearly empty bladder. "The stopcock of the elastic bag was next adjusted to the catheter, and tepid water to the amount of three bagfuls injected through the instrument. Each portion when introduced was retained for a couple of minutes,

and then allowed to return through the catheter, so that not more than eight ounces were injected at a time into the abdominal cavity. At first the water returned was of a reddish tinge, but the last half-pint was clear and bloodless. Each bagful regurgitated in a slow and interrupted manner, and pressure had no influence in accelerating or otherwise altering the mode of its discharge. During these proceedings, which occupied about twenty minutes, the patient was caused frequently to change his position, so as to mix the injected fluid as much as possible with whatever urine remained in the peritoneal sac."

This account yields strong proof—to my mind, at any rate—that there was no rupture of the bladder at all. Eight ounces of fluid were injected each time, and each time eight ounces returned, showing that they entered and passed from a circumscribed cavity—viz., from the unruptured but incapacitated bladder, and not, as asserted, from the peritoneal cavity. If the tepid fluid had really passed into the peritoneal cavity the patient would have experienced during the injection some unwonted sensation, as in Mr. Heath's own case, and exactly the same quantity of fluid would not have been recovered. Moreover, if the catheter had entered the peritoneal cavity a far larger quantity of urine should have been withdrawn. Yet the total amount of reddish urine evacuated by the catheter in its various excursions did not exceed twelve ounces, a decisive proof of the want of distension of the bladder at the time of the accident. No wonder that Dr. Max Bartels (*a*) declines to regard the case as an intra-peritoneal rupture. He suggests that there may have been an extra-peritoneal rent, and that the urine was collected in a pouch of peri-vesical areolar tissue, into which the point of the catheter passed on manipulation; but if my criticism holds good this explanation is superfluous. I now come to the cases related by Dr. MacDougall (*b*). The first case, was under the care of Dr. Thom, of Brampton, and was seen also by Mr. Page, of Carlisle.

R. B., a farmer, had been drinking freely at market. He passed his water at 2.30 p.m. He left for home in a heavily-loaded cart at 3 p.m., but stopped for a little while at a public-house on the way. In passing through a gateway he was thrown out of the cart, and the wheel passed over his belly. He lay for about an hour. Was then found and carried home at 8 p.m. When he was seen by Mr. Thom two hours later the symptoms were—great pain in the belly, great desire and inability to micturate. There was a bruise extending from the left crista ili across the pubes; a deep abrasion on the dorsum of the penis; and a fracture of the ilium, not extending into the true pelvis. A gum elastic catheter drew off, with pressure over the bladder, six ounces of urine deeply-coloured with blood. The catheter did not move freely in the bladder, and it required constant pressure to get the urine away. The pulse was 88 and weak; the face flushed; but the countenance did not express much anxiety. Being very drunk, he threw himself about the bed in the most violent way. Beyond a rapid pulse, and respiration, and tender, distended, and tympanitic abdomen, there were no symptoms of ruptured bladder. On the following day Mr. Page himself remarked that "he seemed to bear the injury remarkably well, there being no marked evidence of abdominal shock." Opium, rest, and the retention of an elastic catheter comprised the treatment. On the third day he was better; on the fourth much improved, the abdomen being less swollen, and some dulness which had been noticed for two inches above the pubes had all but disappeared. The urine flowed freely through the catheter, but became purulent and ammoniacal. Directly the catheter was removed the patient made water freely and well, and the pus disappeared. A rapid recovery took

(a) Dr. Max Bartels's view is supported by Dr. E. Vincent in his valuable monograph, "Plates Pénetrantes Intra Péritoneales de la Vessie," Paris, 1881.

(b) *Edinburgh Medical Journal*, January, 1877.

place. The diagnosis of ruptured bladder was made on the following grounds:—1. The patient's bladder was probably much distended at the time of the accident, as he had been drinking freely, and had made no water for some hours. 2. The wheel of the cart had passed over the region of the bladder with sufficient force to fracture the ilium. 3. Only six ounces of urine came by the catheter when it was first used, and only flowed when pressure was made above the pubes. Lastly, there were signs of severe peritonitis. The impartial critic would at once concede that if the wheel of a heavily-laden cart had passed over the hypogastric region when the bladder was distended, the organ would certainly have been ruptured. But was the bladder distended, or did it contain more than a few ounces of urine, or sufficient urine to make it rise well above the pubes? My reply would be decidedly in the negative. Not alone the absence of the severer symptoms of ruptured bladder, not alone the rapid recovery under the simplest treatment, compel me to this conclusion. Confirmation is obtainable from the history itself. The patient had been drinking heavily at market. His distended bladder urged him to the ural at 2.30 p.m. From 2.30 p.m. to 3 p.m. he was probably not drinking, but superintending the harnessing of his horse and the preparation of his cart. At 3 p.m. he departs, but stops for a glass of ale at a public house. Very shortly after he is thrown out of his cart whilst passing through a gateway, and lies for a considerable time—it may have been two or three hours—before he was picked up. Not improbably the wheel of the cart pressed the bladder backwards, causing extravasation of blood and bruising of the tissues, including the peritoneum and the bladder itself. In this way the small quantity (six ounces) of sanguineous urine drawn off with the catheter is explained, and there is no need to invoke the aid of so fatal a lesion as intra-peritoneal rupture of the bladder to account for the temporary incapacity of the organ, and a moderate attack of traumatic peritonitis.

(To be continued.)

A HISTORICAL SKETCH OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND. (a)

By ARCHIBALD H. JACOB, M.D., F.R.C.S.,

Professor of Ophthalmology, and Councillor in the College; Ophthalmic and Aural Surgeon to the Richmond, Whitworth, and Hardwicke Government Hospitals.

(Continued from page 4.)

SHORTLY after the incorporation of the College, a code of bye-laws was enacted, some of which remain in force to this day; others of them we have grown out of long since, but they are both instructive and interesting as illustrating the manners and customs of our profession a hundred years ago. Evidently our ancestors in the surgical profession were most anxious to disassociate themselves from the barber-surgeons and keep their community select, for we find it strictly forbidden to consult with others than regular surgeons, or to refuse to consult with those within the pale.

A Bye-law declares "That every Member, Honorary Member, or Licentiate of the College who shall consult with any other Member, Honorary Member, or Licentiate, and whosoever refuses so to do shall be liable to such censure as the College shall think proper to inflict."

A further Bye-law declares, "That no Member, Honorary Member, or Licentiate shall consult with any Surgeon or Practitioner of Surgery usually resident in the City of Dublin who is not a Member, Honorary Member, or Licentiate of the College, and any Member, Honorary Member, or Licentiate who shall be convicted of so doing shall for the first offence be cited to appear and solemnly admonished by the chairman in full College

(a) Being an abstract of an Address delivered at the opening of the session of the School of the College, 1882-3.

assembled, and any Member or Honorary Member who shall be again convicted of so doing shall for the second offence be expelled, and any Licentiate who shall be convicted of doing so shall for the second offence have his Letters Testimonial or Licence withdrawn, and be for ever incapable of being elected a Member of the College."

Another law declares that "Every Member who shall be convicted of having taken with an Apprentice or pupil whom he is to maintain in his house a less fee than two hundred guineas, or with one whom he is not to maintain in his house a less fee than one hundred guineas, shall be expelled, and every Member taking an Apprentice or pupil shall solemnly declare upon his honour, in the presence of the College, either that he has really and *bond fide* received such fee of two hundred or one hundred guineas as the case may be, or that he has not received, nor does he expect to receive, any fee whatsoever."

According to another regulation no Member of the College was allowed to take an apprentice until the pupil had been previously examined by the College and enrolled as a registered pupil. The fund arising from the fees of £5 5s. each paid by such pupils was to "be appropriated to the support of the Professorship in such manner as the College shall think fit."

At that time no one was admitted to the Professor's lectures save the registered pupils of the College, there being no other surgical school in Ireland but that connected with the College; but since then the pupils of all schools have been admitted to the teaching of the College professors, and registration as a pupil of the College has come to be simply the advanced payment of a part of the diploma fee in consideration of the pupil receiving the privilege of studying in the library and museums.

The appointment of Professors in the College was provided for by the 17th Bye-law, which empowered the College "to elect a Professor or Professors, who shall annually give a regular course or courses of Lectures on Anatomy, Physiology, the Practice and Operations of Surgery and Midwifery."

At its first incorporation it would seem that the College exercised certain functions which have long since lapsed. It was frequently called upon to arbitrate in professional disputes, and by Bye-law 26 every Member or Licentiate was forbidden to "accuse any other Member, Hon. Member, or Licentiate, of malpractice or mistake out of the College, or give countenance to such accusation made by others, under such penalty as the College shall think proper to inflict."

Another duty of the College was to advise its Members and Licentiates who resided at a distance respecting the diagnosis and treatment of obscure diseases, and I find recorded several occasions on which the College assembled specially, debated the reports of the case submitted to them, and formally resolved upon the proper treatment to be used.

In these days, and up to the year 1828, you will observe, the College had no Council, and the Members administered the institution, just as the Fellows of the College of Physicians do at the present time. They paid an annual subscription of £1 1s., "towards establishing a library and defraying the necessary expenses of the College," and were bound with the utmost strictness to attend the Collegiate meetings, were rigorously fined if absent, and if they omitted to pay, were not only debarred from taking part in the College meetings, but were charged with interest at the rate of 120 per cent. on their overdue fines.

The College at this time was to a certain extent dependent for dissection material upon the bodies of executed malefactors sent to them by the sheriff, and in our museum we have the skulls of several such persons.

Some years afterwards, when the Members of the College were agitating for a grant of money to erect buildings, it suited them to use the occasion to bring the need of dissecting-rooms before the Government, and they

accordingly refused to receive the body of one Frederick Lambert, brought them by the sheriff, who was therefore obliged to fetch it back and dispose of it as he best could.

It will be recollected that at the time of its incorporation the College had no local habitation, a deficiency which it lost no time in remedying. No sooner had the charter been received than the College began to press the Government for a grant to help it to build a house. Pending the issue of its attempts in this direction, it met until 1787 in the Rotundo Lying-in Hospital. Some difference seems to have arisen between the College and the Hospital Governor, for it flitted at that time to the house of the Secretary, James Henthorn, in St. Andrew's Street, where it held its meetings until 1790.

Five years previous to this date the embryo of the School of Anatomy and Surgery attached to the College was vitalised, and the teaching faculty of the College has since developed to a condition of perfection of which we all may well be proud. In 1785 Mr. Halahan laid before the College a scheme for the systematic teaching of anatomy, and his scheme was immediately reinforced by Mr. Dease, who offered to deliver a course of lectures in surgery at his own expense. Up to this date surgery—such as it was—was taught exclusively in hospitals, and dissections were performed in private houses. The College received with enthusiasm the suggestion of Messrs. Halahan and Dease, and joined those gentlemen in the expense of erecting a small lecture theatre in Mercer's Street, close to Mercer's Hospital, in which theatre the College held its meetings for the twenty years between 1790 and 1810.

In 1786 the Government, for the first time, recognised the College officially, for in that year it handed over to it the function of examining army surgeons and surgeons' mates, and up to our own day the performance of that public duty has been set forth in all the College charters as one of the reasons for its existence and one of its claims upon public support. I am gratified to be able to remind you that within our own time the College has most efficiently fulfilled the important duty of providing surgeons for the Army and Navy, and that its Licentiates have always held a high position at the competitive examinations for admission to these services.

In 1790 the College received its first grant of £1,000 from Government towards erecting a suitable building. It must, however, be recollected that it was not to the aid of Government subvention that the success of the College and its School is due. Before it got a shilling of Government money it had its School in full work, with two professors of anatomy, one of surgery, one of medicine, and one of surgical pharmacy, besides three superintendents of dissections, the equivalent of the demonstrators of our day; and these professors were closely watched in the performance of their duties by the court of examiners.

In the same year, as far back as 1790, a Students' Medico-Chirurgical Society was formed by the registered pupils of the College for their mutual advantage, and with the sanction and approval of the College. That Society existed for many years, has since been resuscitated from time to time with much temporary success, and, I venture to suggest, might again be reorganised with great advantage to the student, who, under the improved conditions of medical education, would have much greater facility for bringing before such a Society matter of general interest.

In 1790 John Hunter became an honorary member of the College. From that year to 1805 the institution continued to make progress in importance and usefulness, and to gain influence. It had, however, only yet received £1,000 of a grant from the State, and it did not cease to agitate for increased resources to enable a College and School to be built. In 1805 it succeeded in obtaining £6,000, which was increased subsequently by the following sums:—In 1807, £9,517; in 1808, £5,300; in 1809, £4,550. These sums, amounting in

all to £29,104, were spent upon the handsome building in Stephen's Green, and upon the School in which we now stand. In 1810 the College finally left its ignoble tenement in Mercer Street, which it sold to Mercer's Hospital for £300, and assumed possession of its new house; but it did not rest from its efforts to render the establishment complete, for we find on record a petition to the Irish Government adopted in the following terms:—

“That petitioners have been enabled, by the bounty of Parliament, to establish in Dublin an extensive School of Anatomy and Surgery, which surgeons and assistant-surgeons to His Majesty are permitted to attend gratis. That this School was established on such liberal principles, and has been conducted with so much attention and success, that a concourse of students has been attracted to it far exceeding petitioners' warmest expectations, and it has thus become a national object of considerable importance. That the petitioners have found the apartments allotted to practical anatomy totally inadequate to the suitable accommodation of their increasing class.”

AN ESSAY UPON HIP-JOINT DISEASE.

By S. D. CLIPPINGDALE, M.D., F.R.C.S.

(Continued from page 529, last vol.)

5. *Inflammation of the round ligament.*—The idea that morbus coxæ commonly commences as inflammation of the round ligament seems to have originated with Mr. Aston Key. Mr. Key published his views upon the subject in a paper which he read to the Medico-Chirurgical Society, and printed in the 18th volume of the “Transactions.” The exact morbid appearances in the case there described were as follows:—“The ligamentum teres was found much thicker and more pulpy than usual from interstitial effusion, the vessels upon its investing synovial membrane were distinct and large, without being filled with injection. At the root of the ligament, where it is attached to the femur, a spot of ulceration in the cartilage is seen . . . the same process also taking place on the acetabulum where the ligament is attached.” Mr. Key then expresses the opinion that “at least in many instances the action is propagated from the ligament to the cartilages and that ulceration of the latter is consequent upon inflammation of the former. The beginning of the affection,” he adds, “is frequently to be traced to a fall, by which the legs have been forcibly separated and the ligament stretched.” Mr. Key founds his view, as already stated, upon the erroneous notion that the round ligament checks abduction. This theory of the origin of hip-disease is supported by one of Mr. Key's successors at Guy's—Mr. John Hilton. South also, in editing the English edition of “Chelius's Surgery,” gives the following instructive case in support of Key's view:—“The child, ten years of age, had been lame in the right hip for five or six months, but had no other symptom of hip disease, no pain on motion nor on pressure, nor any restriction to the motion of his limb till within a fortnight of his death (which was caused by tubercles and effusion into the ventricles of the brain), when he complained of violent pain if the thigh was only slightly moved in lifting him from or to the bed.” Mr. William Adams, who made the post-mortem examination, found “a small abscess, the size of a nut, close to the upper origin of the m. rectus femoris. On laying open the capsular ligament a small quantity of dirty brown fluid escaped. The synovial capsule had become thickened, tender in the sense of being readily torn, granular on the surface, and yellowish in colour. The round ligament and contiguous synovial membrane in the portion of acetabulum uncovered by cartilage had been the seat of inflammation. The vessels were injected, the membrane was thickened, and a small

quantity of lymph adhered to its surface. The state of the membrane and round ligament just described appears to me to be precisely the same as that described in Key's case, but less advanced." Mr. Timothy Holmes, (a) although expressing a different view as to the common origin of hip-joint disease, still seems to cling to this one of Key's. Most authorities, however, reject this view; and Mr. Bryant (b) expresses his surprise at finding "good men and true gravely discussing the question as to the origin of hip disease in the ligamentum teres." Another author, whose name at the present time I cannot call to mind, considers belief in this view of the origin of the affection to partake of the nature of superstition. It is perfectly certain that if the round ligament be bruised, lacerated, or ruptured, inflammation must follow. And this might lead to destruction of the joint, especially if the patient be strumous. But I am in a position to state this fact; that in no one of the pathological museums of London, containing as they do more than two hundred specimens of the disease, is there to be found a preparation, showing beyond doubt that the disease commenced in the round ligament. In the museum of University College Hospital is a specimen (c) described as "Hip-joint disease commencing as inflammation of the ligamentum teres." In this specimen, which is a very neat preparation in wax, the ligamentum teres is intensely coloured, but every other part of the joint appears to be normal. Upon the great trochanter is some caries, with formation of new bone. There is no history attached to the specimen, and apparently there is insufficient proof of there having been anything more than caries of the great trochanter. It is beyond doubt that the round ligament is one of the first structures to disappear in disease of the joint; but this may be explained without admitting that the disease commences there. The ligament receives its nourishment from vessels which pass through it from its acetabular end and anastomose with those springing from the head of the femur. The ligament, therefore, would be likely to perish if these vessels were constricted at either end of it. And this is what really takes place in synovitis of the joint. Effusion into the sub-serous tissue takes place, compression of the vessels supplying the round ligament follows, and this structure ulcerates and eventually disappears altogether. Again, if the round ligament were prone to disease we should expect to find hip disease to be common in any animal in which the ligament is well developed. Professor Robertson, of the Royal Veterinary College, however, informs me that in the horse, in whom the ligament is very large, this disease is never met with; and only rarely in oxen and cattle. Professor Williams, of Edinburgh, in his work (d) also supports this view.

Passing now to those cases in which the hip-joint disease follows and is due to an extension to the joint of disease from some part external to it, it may be stated broadly that any of the contiguous structures, bone, muscle, bursa, &c., may be the starting point of disease which ends in destruction of the joint. The most common of the extra-articular causes, however, are—Psoas abscess, and inflamed bursa, and necrosis of the shaft of the femur. A few remarks will be offered on each of these.

1. *Psoas abscess* has been known to occasion hip disease in several cases. This is brought about by the matter perforating the capsular ligament where this lies beneath the muscle. In entering the cavity of the joint, however, the pus appears to do so, in the majority of cases, by first passing through the bursa which lies between the muscle and the joint, and usually communicates normally with the latter. In the London museums there are three very clear specimens of this

condition—viz., one in St. Bartholomew's, (a) one in Guy's, (b) and one in St. George's. (c) In a remarkable case under my own care the disease, which succeeded Pott's curvature, was bilateral, suggesting that there had been double psoas abscess causing double hip-joint disease.

2. *Inflammation of bursa* lying beneath the psoas muscles, independently of psoas abscess, or inflammation of any other bursa contiguous to the joint, may cause its destruction by impaction. An illustrative case, in which the disease followed a buritis at the back of the joint, is recorded by Athol Johnstone. (d)

3. *Necrosis of the shaft of the femur*.—Hip joint disease occasionally, but rarely, results from extension upwards of disease from the femur. This has clearly been the case in a specimen in the museum of Middlesex Hospital. (e) And in Guy's Hospital museum are two specimens (f) illustrating the extension of disease from the trochanter major.

The views above given as to the seat and modes of origin of hip-joint disease may be tabulated as follows:—

- I. Cases of ordinary origin begin as synovitis.
 - II. Cases of extraordinary origin begin as:—
- | | | |
|-----------------|---|--|
| Articular | } | a. Deposit of tubercle in synovial membrane. |
| | | b. Deposit of tubercle in articular cartilage. |
| | | c. Deposit of tubercle in bone. |
| | | d. Inflammation of bone. |
| | | e. Inflammation of round ligament. |
| | | f. Psoas abscess. |
| Extra-articular | } | g. Inflamed bursa. |
| | | h. Necrosis of femur or innominate bone. |

Clinical Records.

CASE OF ABORTIVE APOPLEXY.

Under the care of WILLIAM DONOVAN, L.R.C.P., L.R.C.S.
Ed.; Medical Officer to the Ashby-de-la-Zouch Union;
Health Officer to the Whitwick United District, Leicestershire.

On June the 19th last, I saw Mrs. K., æt. 47. She was then apparently suffering from an abortive attack of apoplexy. Under bromide of potass and an aperient this passed off. Next day she complained of a pain in the right foot, which appeared swollen and congested. She was directed to use a stimulating liniment, the foot to be kept in an elevated position. I saw her again in a few days, when the foot appeared shrunken and dark in colour, and hard. The hardening went on gradually, until the foot appeared as if made of black marble, a line of demarcation beginning to appear in the middle third of the leg in about ten days. She was then ordered ammonia and cinchona, the foot and leg being kept wrapped in "carbolic tow." On the 29th of August, the line of demarcation being fully established, I amputated the leg about an inch above it, Dr. Wilson, of Sheepshed, kindly assisting me. During the operation there was no loss of blood worthy of mention, and on easing the tourniquet none at all, except a slight oozing from the cutaneous vessels. Seeing nothing to point to hæmorrhage, I put up the flaps in the ordinary way, having washed them in "sanitas fluid," and enveloped them in "sanitas gauze." There was no further trouble, and on the 29th I took out the sutures, the stump being to all intents healed. I did not see the case again until the 3rd of this month, having gone to America for a holiday trip in the interval. On that date the stump appeared all that could be wished. The facts of interest appear to be the complete

absence of hæmorrhage—no ligatures being required—the rapid healing of the stump, the absence of suppuration or secondary hæmorrhage, which I had anticipated.

Germany.

[FROM OUR SPECIAL CORRESPONDENT.]

A TWIN MONSTER.—M. Paul Bert has had the opportunity of examining a living twin monster at Geneva, which differs in many respects from any of the modern show cases. It is a male child five years of age, possessing two heads, two thoraces, four arms, one abdomen, and two feet. The fusion of the two bodies takes place at the umbilicus, so that above this point there are two individuals, but below, only one. Notwithstanding the anatomical unity as regards the lower half of the body, physiologically or psychologically this part is dual. Each individual claims the extremity of its own side as its own: they play and strike each other with their respective *leg*. Their features are exactly alike. Their mental development is fair; they speak French, German, and Italian. They are quite healthy, but rather anæmic. They cannot walk. They are two distinct beings, and quite independent of each other mentally. The sensations of hunger and thirst are not simultaneous: if one eats the other is not satisfied. The duality of the stomach requires a dual satisfying of the food-requirement. They have been baptised separately under the names of Jean and Jacques. In describing the above case P. Bert mentioned that of the court jester of James the IV. of Scotland, who was a monster of a similar kind. Of the two beings of which it was composed one was full of intelligence, wit, and *verve*; on account of his beauty, as well as of his mental gifts, the pet of the court ladies; whilst the other was disgustingly idiotic, and so addicted to drink that in a drunken fit he at last smote his brother, from the effects of which both died. The two individuals could not live in peace; they struck one another and used to snatch the wine flask out of each other's hands, the one that he might drink, and the other to throw it away.

THE WATER BED FOR LYING-IN.—A woman, 22 years of age, in the 8th lunar month of pregnancy, the subject of Bright's disease, with great œdema, was transferred from the Medical Klinik of the Vienna Hospital to Professor Braun's department, for the purpose of having premature labour induced. The œdema of the external genitals was so great that gangrene had set in, commencing at the nymphæ. As a person in such a state brought into a lying-in hospital would be likely to prove a focus of infection for the other inmates, Professor Braun had her placed in an isolated room, provided with a separate nurse, and told off a special medical attendant to take charge of her. So far the pulse and temperature were normal, and he (Prof. Braun) determined to await for a short time the course of events, in the meantime washing out the vagina with a 3 per cent. carbolic solution, applying thymol dressings, and placing her upon generous diet. He came to this determination from believing that premature labour was not urgently called for, and from a strong objection to do anything that might lead to the carrying of any infective material into the uterus; "and to undertake anything that might possibly cause the death of the mother, for the sake of a foetus whose vitality is doubtful, I consider unjustifiable." Thus three days passed in expectation, on the fourth the temperature rose to 40° C. (104° F.), and on the fifth day a living child was born, weighing 2,100 grms. As the gangrene had now extended to the thigh, and threatened to advance still further, she was at once placed in a bath. Up

to the time of writing she had been in five days, during which time she had remained free from pyrexia, the gangrenous places had cleaned, her appetite was good, and there was every hope that her life would be saved. Prof. Braun concludes: "But this hope is entirely due to the water bed. It sounds strange, and up to the present such a procedure as putting a lying-in woman into a warm bath has scarcely ever been carried out. But theoretically, there can be no objection to it. In the case of our patient, the water bed, with its continual irrigation, and washing away of putrid and infective secretions, and thereby avoiding the absorption of them, was the only way by which her death could be prevented. Her general condition is as good as can be wished, she is quite comfortable in the water, and we are delighted to have brought her thus far in safety on the one hand, and on the other to have saved our Institution from the perils of infection."

SIR ROBERT W. JACKSON, C.B.,
Brigade-Surgeon, A.M.D.

We should be remiss did we not make mention in our columns of the services of this distinguished medical officer, who has just returned from the Egyptian campaign. Sir Robert Jackson served with the 90th Light Infantry in the Crimea from the 5th of December, 1854, including the siege and fall of Sebastopol, and then returned to England in medical charge of the regiment.

During the Indian Mutiny was in medical charge of a Battalion at the relief of Lucknow by Lord Clyde, present at the battle of Cawnpore on the 6th of December, 1857, was with Outram's force at the Alumbagh assault and capture of Lucknow, in medical charge of the Camel Corps at the assault and capture of Calpee, present at the capture of the Forts of Dehaigh Tyrhool, in Oude, also during the final operations of Jugdespore. On the voyage homewards from Calcutta in sailing ship *Pomona* an outbreak of cholera occurred; there were 49 cases and 27 deaths. He was alone in medical charge until arrival of General Browne and Surgeon-General Anderson, who brought another medical officer; was thanked by the General and favourably reported on by Major Edmonstone, commanding troops on board the ship *Pomona*.

Accompanied Sir Garnet Wolseley to the Gold Coast in September, 1873, and served throughout the Ashantee War of 1873 and 1874, including the action of Essama (again thanked for his valuable services), relief of Abakrampa (on this occasion contracted fever and was sent on board H.M.S. *Simoom*, and a board recommended invaliding home, but he obtained permission to return to duty), present at the battle of Amoafu, battle of Ordashu, and capture of Coomassie, and was in medical charge of the 1st Field Hospital from its formation to the end of the campaign (mentioned in despatches C.B.).

Volunteered for service on occupation of Cyprus, received thanks of Military and Medical Departments, and specially reported for having carried out professional duties with zeal and ability during the great sickness which prevailed in the summer of 1878.

Volunteered for, and served during, the campaign in South Africa. The General commanding at the attack on Secoconi's stronghold reported in very commendatory terms on the service of Surgeon-Major Jackson, and of the efficiency with which he dressed the soldiers' wounds under fire.

Volunteered for, and served on, Egyptian campaign at actions Tel Mahutu, Magfar, Kassassin, and Tel-el-Kebir, and mentioned in despatch as follows:—

"Brigade-Surgeon Jackson has served in all parts of the world, and in the many wars in which he has taken part has distinguished himself throughout by his coolness under fire, and in zeal as a medical officer, I would venture to recommend his special promotion."

He was three times in medical charge of the Royal Infirmary, Phoenix Park; an important charge, which it is believed has not in any other instance been held a second time by the same medical officer, although applied for.

Sir Robert Jackson has the following rewards, received from the Executive Department:—

For Crimea, medal and clasp and Turkish medal; for India, medal and three clasps; for Ashantee, medal and clasp, and C.B.; and for South Africa, medal and clasp; for Egypt, medal and clasp, and the honour of third-class Medjidie, knighthood.

Sir Robert Jackson, still on full pay, will soon retire from the Army Medical Department. We congratulate him on his distinguished career, and trust that he may long be spared to enjoy the honours he so justly merits.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 10, 1883.

THE CASE STATED AGAINST THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES BY THE ATTENDING PHYSICIAN.

—No. V.

On the last occasion on which we discussed this subject we pointed out a very serious objection to the working of the proposed law, grounded upon the fact that, if the physician does not please to notify, no power on earth can make him do so, and no Act of Parliament can punish him for omitting to do so. We remind our

readers that the diagnosis of an infectious disease is a simple matter of professional opinion, and that no man can be prosecuted or punished for making an incorrect diagnosis, or forming an inaccurate opinion.

For how is the physician to be punished? It is true he may be summoned to the police court and charged with an offence against the law; but it is also true that no evidence can possibly be produced which can convict him. He has only to say that he did not recognise the disease as infectious, or boldly assert that it was a case of nettle rash, or some other non-infectious disease, and he *must* be discharged free. True, he may be called an ignoramus by the medical officer of health for not recognising such obvious symptoms, but no further penalty can be inflicted on him, seeing that stupidity or ignorance of the symptoms of disease are not crimes punishable by law. We have pointed out that this anticipated difficulty in enforcing the law does actually arise, and does prevent any person being punished for omission to notify. In the seventeen towns in which notification by the physician has been in force for years past, not a single successful prosecution has been carried through, though the omission to notify disease has been palpable in every one of those towns. In Edinburgh and in Bolton prosecutions have been successfully carried out, but on these occasions no such defence was made. In these cases the recalcitrant physician pleaded simply either that he did not know the law, or that he objected to it, neither of which pleas were, legally, of any avail. But he did not say, as he might have done, that he denied that the case was infectious, or that the symptoms were not such as to make its character certain. If he had made this defence no prosecution could have been maintained, and in point of fact, wherever such plea was put in the attempt to punish the physician completely broke down. So fully is this difficulty of enforcing the law recognised by medical officers of health, that, speaking generally, notification, though compulsory in theory, is purely voluntary in practice. We challenge denial of the statement that, as a rule, physicians practising in notification towns report cases which they can report without doing violence to their patient's wishes, and that they abstain from reporting cases which the patient's friends desire to conceal. In fact the penal clauses of the Notification Acts are, and must always continue to be, a dead letter as long as they are directed against the physician and based upon the erratic judgment of a practitioner respecting the diagnosis of an obscure disease. We therefore ask again in Parliament to be asked to enact a law which is unworkable, has failed in practice, and, in the most favourable case, must prove troublesome and unmanageable? But, to our mind, one of the strongest objections to the proposed law is that its inevitable effect must be, and has been to divert practice from the hands (and pockets) of conscientious and competent physicians to those who are ignorant and scheming, and to encourage by the strongest incentives the existing disposition of the lower-middle classes to resort for advice, to counter prescribing chemists, and other unqualified persons. Should this pernicious law become general it is easy to see how the tide would flow. The conscientious physician, being called to attend a case of infectious disease, will do his

legal duty regardless of the feeling of his patient, and in all those cases in which concealment is desired, will suffer the consequent penalty of losing his patient, his money, and his reputation, whilst the practitioner whose purpose is to make a practice and conciliate his patient, will find all the excuses which the proposed law affords to abstain from notifying.

Let us not pretend to more virtue for medical men than for other classes of practitioners of similar social standing; and let us, therefore, not forget that a very numerous section of our profession will certainly not, if they can help it, do anything which will interfere with their own interests in practice. With such practitioners "Business is business." If the notification fee is half-a-crown they will notify for the purpose of earning it; but if it pays them sixpence more to pretend not to recognise a case of infectious disease, they will certainly be very slow to find out what in reality is wrong with the patient. If they are earning daily fees by attendance on a case in private, they will scarcely be expected to put an end to their own profits by reporting the case, and thus causing it to be taken off to hospital.

Thus, in every town where compulsory notification has been enacted the conscientious-timid practitioner has suffered seriously by his infectious cases being diverted into the hands of less honest persons; and it is evident that the inevitable effect of such law must be to handicap honesty in practice heavily in its competition with the trade trickery which is an important element in the success of low-class practitioners.

But it should be recollected that if all medical practitioners were of spotless integrity the effect of compulsory notification upon the public health would be still worse, because the law would then transfer to counter-prescribing chemists and quacks the practice in infectious disease, which it now hands over to low-class medical practitioners. The proposed law does not in any way interfere with the counter-prescriber's practice. He is not amenable to it in any way. He may visit small-pox patients, treat them, and conceal the disease all through, and cannot be even asked to report, much less punished, for omitting to do so. If, therefore, the custodian of any infected patient desires to escape the publicity and inconvenience attendant upon the notification of the case to the sanitary authority, he may at once escape all trouble of the sort by resorting to a chemist or quack practitioner. Thus, notification law, wherever enforced, has always increased unlicensed practice at the expense of legitimate medicine; and it must always have such effect as long as the physician and not the custodian of the patient is the person responsible to notify.

SUDDEN DEATH.

AN ingenious apparatus has been described by Mr. Lane Fox in a recent issue of the *Zoophilist*, which has been designed for the purpose of putting an instantaneous and humane end to worn-out horses or pet animals of any kind. On the floor of an ordinary stable stall an iron plate is fitted, and with this is connected the negative pole of an electric condenser, formed of alternate layers of tin-foil and tissue paper soaked in

paraffin. This condenser is charged from an ordinary coil to its full capacity of a hundred micro-farads, and is to be discharged at an electro-motive force of 15,000 volts, which produces a one-inch spark. The animal to be despatched having had its head, feet, and legs sponged with salt water, is placed on the iron plate, and is then touched on the forehead by a brass knob fixed in an insulating handle, and connected with the positive pole. It falls dead at once, without a struggle or movement, being, in fact, killed instantaneously and simultaneously in its every tissue. No more sudden or painless form of death is possible. The effects of electricity on the muscular substance of blood in relation to cadaveric changes must prevent the adoption of this process for the slaughtering of animals whose flesh is to be used for human food; but that it will be extensively employed for putting an end to old and diseased animals cannot be doubted, as it will at the same time spare their feelings and those of their owners. It is almost to be hoped, too, that it will be adopted as a means of inflicting the penalty of death upon criminals. There is, unfortunately, no prospect that we shall be able to dispense with capital punishment for some time to come; but we may at least do our best to dispense with the torture and physical anguish which now, it is to be feared, too often accompany it. A review of the executions which have taken place in this country during the last ten years would reveal an amount of bungling that would startle the public when thus summed up, and that can only be pronounced scandalous. Within the last month two shocking scenes have been enacted on the gallows. In the case of Myles Joyce, hanged at Galway, the rope caught on the arm of the wretched man, who seems to have made a grim fight for life until the foot of the executioner, as it were, kicked him into eternity; and in the case of Taylor, hanged at Wandsworth, the long drop tore open the wounds which the convict had inflicted on his own throat in an attempt at self-destruction some months previously, and his head was nearly severed from his body. We have no hesitation in saying that misadventures like these more than counterbalance any public benefit derived from the example afforded in the cases in which they occur, for all recollection of the guilt of the criminal is swallowed up in commiseration for the torture he has endured. But even when accidents such as those we have referred to do not occur, there is reason to believe that executions in this country are often accompanied by much unnecessary pain, and that the long drop does not possess the advantages which are alleged in its favour. Death rarely takes place, it is believed, at executions by dislocation of the neck, but most often by slow strangulation. The statement that death was instantaneous is only a stereotyped phrase, or a compliment paid by the hangman to his own work, for no one but the hangman can say how long the death agony was prolonged. The moment that the bolt is drawn the body falls into a pit or behind a black curtain, where no one but the executioner has a view of it, and the small group of spectators now present at an execution cannot pretend to say how long the death struggle continues. Now that executions are

in private, this veiling of the process seems quite unnecessary. It ought, we think, to take place in full view of the persons whose duty it is to witness the execution, and of the representatives of the public, so that some guarantee may be obtained against unskilfulness and the infliction of unnecessary suffering.

It behoves the Home Secretary to give his careful attention to this matter, and to see whether Mr. Lane Fox's apparatus cannot be substituted for the clumsy appliances now in use for the execution of criminals. Death by electricity is absolutely painless; but it is so sudden and mysterious that it would not be less deterrent to the criminal classes than the more primitive and familiar death by hanging.

Medical jurists will have to give very close and earnest attention to the signs of death by electricity, for it can scarcely be doubted that we shall have murder by electricity before long, and at present no indications are known by which that mode of death could be sworn to. Far less contrivance and money than were expended in the Peltzer case would suffice to arrange a murder by electricity, which would in all respects resemble a death by the visitation of God.

QUACKERY IN GERMANY.

Not long ago we referred to the above subject, and incidentally mentioned that quackery must be a hardy plant to flourish, as it apparently does, in the uncongenial soil of Germany. The subject of quackery comes home to every one of us, to the laity not less than to professional men. Those who make our laws have in a purblind sort of manner become cognisant of this truth, and have in their wisdom decreed that the public shall have the power of distinguishing practitioners of medicine whose education shall have received an official stamp from those who have given no guarantees of their fitness for their calling. So far our Legislature has gone, but no further. So far it has given to the profession a *trade mark*, and has allowed the use of it to every qualified and registered practitioner, but at this stage its active watchfulness over the exercise of the healing art has ceased. Should this be so? Is there no further room for improvement? It has done for an important body of citizens fitly educated, and at great expense of time and money, for perhaps the most important duties, from a statesman's point of view, that any body of men can exercise—viz., looking after the lives and health of their fellow-men; it has done for this body of educated men just what it will do for any individual on the same terms. We believe that any man can register a trade-mark for the sum of five guineas or thereabouts, and such a registration gives the individual thus registering the exclusive right to the use of the trade-mark so registered. A medical man, however, properly qualified, registers, and his registration gives him the right to the use of a *corporate trade-mark* only—that is, the right to style himself "physician," "surgeon," "registered medical practitioner," or "apothecary," a right, however, which is anything but exclusive, since it is the common property of some thousands besides himself. A property in a common trade-mark, then, and a power of recovering payment in

a court of law for service rendered are all the advantages, independent of social ones, or nearly all that a qualified man acquires by virtue of his diplomas and registration. There is no sort of watchfulness on the part of officialism that these poor and empty advantages are secured to him; and the reason is perhaps not far to seek. It is not, however, our business at present to go into this question.

There is a class of officials whom this condition of affairs more nearly concerns. The office of medical officer of health is of comparatively recent institution, and it may not unreasonably be supposed that its duties at present are not very clearly defined, and that the sphere of activity of its incumbents might easily be widened with benefit to the community whose servants they are.

These remarks are intended to introduce an interesting narrative, one that offers a whole crop of suggestions to any one who may choose to gather them. We commend it specially, however, to the notice of medical officers of health, as recent vigorous endeavours on their part made in furtherance of the compulsory notification of infectious diseases, or compulsory tale-bearing, as it might not inappropriately be called, seem to show that they are not wanting in zeal for the public good, whatever may be thought of their discretion.

The narrative is that of a trial in Germany a few days since, in which the plaintiff was a certain quack named Mohrmann, who styled himself *Heilkünstler* (literally, health-artist), and the defendant a medical man named Pfeiffer, who filled certain public offices, amongst which that of public analyst was included. Mohrmann was principally engaged in vending a nostrum for the cure of tapeworm, and Dr. Pfeiffer, in the course of what he conceived to be his duty, had procured a sample of the drug whose virtues were vaunted, and had submitted it to chemical examination. It turned out to be castor-oil, to which some colouring matter had been added. Having discovered so much, he now thought it his duty to warn the public against the imposture. This he did in the public papers, and in doing so made use of language the reverse of complaisant from the plaintiff's point of view, inasmuch as he described Mohrmann's occupation as swindling. The consequence of Dr. Pfeiffer's official interference was that Mohrmann's business came to a standstill—nobody would any longer believe him to be a worker of miracles, nor would they buy his wares.

He, on his part, thought Dr. Pfeiffer's interference officious and unjustifiable. He had put himself to great expense in advertising in the papers, periodicals, and in placards, and he now brought an action before the Königl. Schöffengericht (an inferior court) of Wiesbaden, for damages for defamation of character, and for the recovery of the sums spent on advertising. Dr. Pfeiffer appears to have treated the affair with perfect calmness, and when the case came on for hearing pleaded justification. His plea was a categorical one, and on the whole seems to give evidence that the defendant was equal to the occasion. The following will give some notion of the defence. 1. That Mohrmann, in his mountebank-like publications, had enumerated symptoms as evidence of tapeworms, that might be present in various kinds of sickness, whereas the only reliable proof of their presence

was the expulsion of segments. Mohrmann plainly intended to make as large a circle of readers as possible believe that their bodies were the dwelling places of these unpleasant guests, in order that he might profit by such a belief. 2. The drugs employed by Mohrmann were such as taken in large doses would act powerfully, and easily produce injurious effects. The dangers to the patient would be the greater, as the plaintiff, through lack of education, would not be able to decide whether the state of the patient's health would permit such violent remedies to be used, and, as a matter of fact, he did not trouble himself to learn whether it did or not. 3. The charge made by Mohrmann for his medicine, inclusive of consultation and trouble, was 10s. (at first 6—15s.) although the actual value was not much above 1s. 2½d; although, as a rule, a consultation was dispensed with, and his trouble consisted simply in sending the order for the medicine to a certain chemist, with whom he had a contract. 4. The plaintiff, plainly for the purpose of deceiving, coloured the castor oil made use of, a red colour; although this was never done by medical men. 5. The whole art and manner by which Mohrmann sought to dispose of his wares smacked of cheating. Thus he lauded himself "world-renowned! unique! not to be excelled!" ; whilst the fact was that he was not the discoverer of the method of treatment made use of, and that one of the drugs employed belonged to a class that has fallen into disuse, as far as scientific medicine is concerned. 6. The plaintiff multiplied orders and titles to himself (to which he had no claim) in order that he might appear as an educated man of high position in the eyes of that portion of the public that is easily led captive by such simple means. He gave himself out to be the possessor of an Austrian Order, which, as far as he, the defendant, could discover, had no existence; further, he decorated himself with the appellation, "Member of the Free German Hochstift, Frankfort-on-the-Maine," an institution which not only had "nothing to do with tapeworms," and was simply a society of men specially interested in art and science, but which only accepted his proposal for admission on the strength of his declaration that he was a private individual, and which had at once expelled him as soon as the fact that he had abused his membership came to be known.

From all this, his endeavour to pass himself off as a notable was plainly seen (he was a watchmaker by trade, and lately practised as a photographer), and he was absolutely without scientific training. Dr. Bickel, Kreisphysikus, who gave evidence as an expert, confirmed the evidence of the defendant with regard to the money value of the ingredients of Mohrmann's medicine.

Judgment was delivered some time afterwards, and was in favour of the defendant on all points; on the grounds, amongst others, that the defendant had published the warning that was the cause of the action in the course of his duties as public inspector of articles of consumption as food, &c. (a department of public health), that only the concluding part of the warning, at the most, was libellous viz., that in which mention was made of swindling; that this concluding sentence was, however, not so much a reproach as a judicial conclusion drawn from what had preceded it; that the manner in which Mohrmann conducted his business might fairly be described as mountebank-like;

and that the defendant was entitled to the protection of the law, inasmuch as his action could not be looked upon so much as an injury to an individual as a benevolent warning to the public.

Would not some of our own public medical officers be better employed in warning the ignorant and credulous against the "reverend" and other impostors that wax fat by means of the so-called "religious" press, than in doing their little all to get compulsory tale-bearing acts forced on their brethren.

MEDICAL REFORM.

THE following petition, adopted by the Executive of the Irish Medical Association, was presented on Friday last to Mr. Mundella, M.P., at the Privy Council Offices, by Dr. Jacob, who was deputed to do so. It will be observed that the memorial is a reiteration of the opinions already expressed on many occasions by the general meetings of the members of the Association, and a reaffirmation of the policy to which the Association was pledged by its petitions to Parliament.

We are gratified to learn that the Reform Bill is already drafted and submitted to the Cabinet, and will certainly be introduced early in the session with the serious determination of Government to pass it.

TO THE RIGHT HONORABLE THE LORD PRESIDENT OF
HER MAJESTY'S PRIVY COUNCIL.

*The Memorial of the President and Council of the Irish
Medical Association*

HUMBLY SHEWETH—

That your Lordship's memorialists are the executive body of an incorporated Association which numbers amongst its members more than one-third of the entire body of registered medical practitioners in Ireland, and which for more than forty years has been maintained in order "to unite the members of the medical profession in Ireland, and so form a body competent to exercise influence in sanitary and medical affairs for the public benefit, and to protect and promote the interests of the medical profession."

That your Lordship's memorialists have learned with much satisfaction that it is the intention of Her Majesty's Government to introduce to Parliament a Bill for the amendment of the Medical Acts based upon the recommendations of the Royal Commission appointed in the year 1882 to investigate the subject.

That the Irish Medical Association has, at many successive annual general meetings, declared its approval of the principles embodied in the recommendations of said Royal Commission, and has petitioned Parliament in favour of those principles, and furthermore expressed its opinion thereon by testimony given on its behalf before said Royal Commission.

That your Lordship's memorialists will be prepared to give the best support of the Irish Medical Association to any Bill which embodies the following principles:—

a. To restrict the privilege of registration as a medical practitioner to persons who shall have passed before a Central Examining Board for each division of the kingdom an examination adequate to ensure their competency, registration being granted throughout the kingdom upon equal terms as regards standard of examination, duration of study, and amount of fees payable prior to examination.

b. To reconstitute the General Medical Council so that an adequate direct representation therein of the registered medical practitioners throughout the kingdom shall be secured.

c. To amend the existing law so as to check effectively

the prevalent practice of medicine and surgery by uneducated and unlicensed persons, and the use by such persons of titles calculated to deceive the public as to their competency to practise.

Your Lordship's memorialists therefore humbly pray that Her Majesty's Government will take steps during the next Session of Parliament to have the existing law amended in these respects.

Signed,

JAMES MOLONY, F.R.C.S.I., President.

JOHN H. CHAPMAN, F.K.Q.C.P.I., Honorary Secretary of the Irish Medical Association.

Notes on Current Topics.

Egyptian Plague.

IN so insanitary a condition was Cairo when it fell into the hands of our troops that for a time it was feared that among other diseases the plague might show itself and drive us out. Remarkable enough, little more is known of this much-dreaded disease than was known in the days of the celebrated physician Clot Bey. The late Mr. Nassau Senior, in his interesting "Journal and Conversations" on Egypt, tells us that, being particularly anxious to obtain information on this scourge of Eastern nations, he entered into conversation with Clot upon its history and treatment. Replying to his questions, Clot said: "The only reliable piece of information I have gained with regard to plague is that it is not transmissible—that it cannot be propagated by inoculation like small-pox, or by contact mediate or immediate, like typhus. For five months, in 1835, my colleagues and myself were in constant contact with plague patients. I inoculated myself twice with the matter from tumours of the stricken and dying. We wore clothes taken off their bodies; we slept in their beds; we made post-mortems of more than a hundred bodies; we tried every mode of exposure, but without one of us being attacked. I used no precaution with respect to my family, but went straight from the plague hospital to my wife and child: so strong was my conviction that plague was not transmissible. The result has been the virtual abolition of quarantine in England and France. Dirt, over-crowding, and bad feeding have nothing whatever to do with the propagation of plague, since these are the normal condition of most Egyptian towns, and the strong and the sober die in nearly the same proportion as the weakly and intemperate." So much for this unaccountable scourge of the Middle Ages, and which has even so come down to us.

Is the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 33, Bombay 26, Madras 31, Paris 25, Geneva 30, Brussels 21, Amsterdam 28, Rotterdam 33, The Hague 23, Copenhagen 23, Stockholm 21, Christiania 20, St. Petersburg 34, Berlin 20, Hamburg 26, Dresden 26, Breslau 26, Munich 29, Vienna 25, Prague 29, Buda-Pesth 28, Trieste 27, Rome 25, Turin 29, Venice 33, New York 22, Brooklyn 20, Philadelphia 23, and Baltimore 28.

Pasteur's Vaccinations against "Charbon."

M. PASTEUR communicated last week to the Academy of Sciences of Paris the statistics of the results obtained by him by vaccinations, protective against "charbon," in a single one of the French departments. The inoculations were practised on 85,000 animals, and the figures show that "charbon," which before inoculation was discovered destroyed 9 per cent. of the animals, had only killed 0.75 per cent. of them since that period. At a subsequent meeting, M. Pasteur read a note, on behalf of MM. Straus and Chamberland, respecting the possible passage of the "charbon" bacterium from the mother to the foetus. This fact has been long denied, but it is now placed beyond doubt. However, the effect is not constant. Pasteur inclines to the belief that the difficulty of so transmitting the bacterium would have the effect of a vaccination, and ought to preserve the foetus thus inoculated. These experiments were made on sheep.

At a subsequent session of the Academy, M. Paul Bert gave the results of some experiments on the germ origin of hydrophobia. The blood of a rabid dog having been transfused into a healthy one, the latter became mad. The saliva of a rabid dog does not communicate rabies by inoculation; it is the froth which comes from the bronchi which conveys the disease; but if the saliva does not transmit the disease, it produces at the spots where it has been inoculated suppuration so considerable that death may follow. The saliva of a rabid animal transforms starch into glucose, just as ordinary saliva. It seems to have undergone no alteration. The saliva of a mad dog filtered through plaster, and inoculated, is harmless, although the part which remains on the filter communicates the disease, which proves, as M. Bert thinks, that this terrible disease is due to the presence of a microbe.

Colour Blindness among Natives of India.

SURGEON-MAJOR CULLEN, of Khundwa, has had an opportunity of making some interesting observations on the existence of colour blindness amongst the natives. Dr. Cullen, during the early part of last year, examined 430 railway employes by Holmgren's method of coloured skeins of wool. The result was the discovery of colour-blindness in 1 out of 86 Eurasians, or 1.6 per cent.; 3 out of 41 Mahomedans, or 7.31 per cent.; and 11 out of 300 Hindus, or 3.66 per cent. Subsequently, Dr. Cullen extended his examination to native children, and found 12 among 471 boys, and none among 68 girls, affected. The proportion among the boys approximates closely to that found among European school children. Further inquiry showed that colour blindness was not associated with myopia or any other defect of vision, and that it was independent of the colour of the iris. At the same time, out of the 430 railway servants examined, Dr. Cullen found no fewer than 35 myopic.

We regret to learn that the defence of Mr. Noake, M.R.C.S.E., L.R.C.P.Ed., of Leeds, to the charge of illegally attempting to procure abortion, and thereby causing the death of a Miss Laidlaw, of Wakefield, was deemed insufficient to release him from suspicion. Both he and Mrs. Hudson have been again remanded.

Mogador as a Health Resort.

NONE of the well-known winter stations, such as Nice, Cannes, Algiers, and even Madeira, can afford to invalids so many favourable circumstances as the city of Mogador. The only actual lack at that place is *comfort*, but this would soon be supplied if patients came. As a compensation, living is very cheap, clean lodgings, good board, and attendance included, costing at the rate of 8s. per day. The difference between the highest monthly average of temperature in summer and the lowest in winter is only 13.5 degrees Fahr., and the difference in twenty-four hours, between day and night, is rarely more than 5 degrees Fahr. This is owing to Mogador being under the influence of the north-east trade wind almost throughout the whole year. Besides this, the same wind, and occasionally that from south-west, keeps in the locality a gently moist and saline atmosphere, and carries away from it all miasmata. In Madeira, the next to Mogador in regard to latitude, there is a difference of 20 degrees Fahr. between the average temperature of the six summer months and the winter average. At Mogador the difference is only 7.9 degrees Fahr. On account, therefore, of its climate, the prospects held out to consumptive and otherwise delicate persons by a resort to that place deserve to be made known, there being every reason to believe that, before long, it will in these respects compete successfully with Algeria, Egypt, Madeira, and the Riviera. There is a splendid sea-beach, several miles in extent, at Mogador, where riding and walking exercise is most enjoyable. The town can boast of English, French, and German Consuls, a resident physician (Dr. Thierry-Mieg), and a missionary clergyman. Steamers ply between Mogador and London frequently.

The following works contain full information regarding Mogador:—"Mogador et son Climat," par Dr. Serex, 1870; "Climat de Mogador," par le Dr. Clin, 1875; "Morocco and the Moors," by Dr. Leared, 1876.

Pathological Society.

At the annual meeting of the Pathological Society, held on Tuesday, January 2nd, the following office-bearers were elected for the ensuing year:—*President*, *J. W. Hulke, F.R.S.; *Vice-Presidents*, W. Bowman, F.R.S.; Thomas Buzzard, M.D.; William H. Broadbent, M.D.; Andrew Clark, M.D.; John Croft; *Arthur Edward Durham; Jonathan Hutchinson; Samuel Wilks, M.D., F.R.S.; *Treasurer*, George Johnson, M.D., F.R.S.; *Honorary Secretaries*, *J. F. Goodhart, M.D.; Henry Morris; *Council*, *Robert Barnes, M.D.; John Cavafy, M.D.; John Curnow, M.D.; *Frederick A. Mahomed, M.D.; Joseph Frank Payne, M.D.; *George Vivian Poore, M.D.; R. Douglas Powell, M.D.; *Frederick Thomas Roberts, M.D.; George Henry Savage, M.D.; Reginald Southey, M.D.; *W. Morant Baker; *William Harrison Cripps, Alban Henry G. Doran; *Alfred Pearce Gould; Thomas Ridge Jones, M.D.; John Langton; *R. Clement Lucas; Edward Nettlehip; Robert William Parker; William J. Walsbam. The gentlemen whose names are marked with an asterisk (*) were not on the Council, or did not hold the same office during the preceding year.

Death of M. Gambetta.

THE unexpected, fatal termination to M. Gambetta's illness, though not caused by the accidental pistol wound of the hand and arm sustained by the distinguished statesman recently, must nevertheless have been to some extent accelerated by this catastrophe. Post-mortem examination of the body has revealed extensive degenerations in the region of the left iliac fossa and ascending colon, of a nature to preclude any hope that might have been entertained of successful operative interference. The termination of the ileum was very much contracted, and all the evidences were discovered of an old-standing perityphilitis, while general inflammation had clearly existed for a long time in the neighbourhood of the ascending colon; in no place, however, was there any collection of pus into an abscess, but rather the whole cellular tissue surrounding was infiltrated with a puriform deposit. The final result is without doubt to be attributed to extension of the inflammatory action to the peritoneum, following the development of acute symptoms in the parts affected with chronic inflammation. Such unfavourable change would naturally ensue as a consequence of lowered vitality induced by confinement and inaction; and more especially on an active temperament like that of the late Republican leader. A most important point, verified by the necropsy, is that any surgical procedure adopted with a view to prolonging the life of the patient would have been attended with disastrous results, and thus the judgment of the eminent surgeons who opposed such a proceeding is fully endorsed by the facts.

This is no place to discuss any aspect of the great Frenchman's death, except that in which the question of medical treatment is reflected; we may, however, be permitted to proffer our deep-felt sympathy with the nation which has thus been deprived of death of almost its most prominent citizen; and of one whose zealous patriotism and noble devotion to his country's cause had gained for him the affection and esteem of a mighty and united people.

A Female Student's Home.

On January 2nd, a new "College Hall of Residence for Women Students" was opened for inspection at No. 1 Byng Place, Gordon Square. In this institution accommodation is provided for a limited number of ladies engaged in studying in London, whether medicine, art, or science; and its arrangements are devised with a view to combining as far as possible the advantages of home associations with academic routine. The scheme deserves the fullest success, and will no doubt command it, for one of the greatest drawbacks attending the prosecution of systematic studies by women in the metropolis is the lack of convenient and economical lodgings within any reasonable distance of their work. Already the whole of the rooms available are occupied, and it is intended at as early a date as possible to extend the present building as far as funds permit.

At a recent conference of members of the British Association held in the rooms of the Geographical Society, a protest was drawn up against the proposed meeting of the Association in Canada in 1884.

The Hounslow Tragedy.

WITHIN the past few days the usually quiet suburb of Hounslow has been a scene of wild excitement and uproar, occasioned in connection with the death by suicide of Dr. William Whitfield Edwardes. This unfortunate gentleman—a late student of St. Mary's Hospital, where his manly, straightforward character gained for him the esteem of teachers and students alike—not long ago entered into partnership with Dr. Whitmarsh, of Hounslow, and appears to have been disappointed in his expectations of the practice enjoyed by the latter. On Christmas day he saw a certain female patient in the ordinary course of practice, and shortly after this she charged him with impropriety in his conduct towards her. The charge was subsequently withdrawn, but in a letter written by Dr. Edwardes before his death, he alludes to his partner's persistency in maintaining his guilt, notwithstanding the woman's recantation. It is certain, indeed, that the occasion was taken by Dr. Whitmarsh to necessitate a dissolution of the partnership, which he demanded on the payment by himself of £500 to the outgoing partner, who, about twelve months ago, had given £1,800 for a half-share of the practice. Apparently distressed in mind at the circumstances by which his position was surrounded, Dr. Edwardes, in a moment of extreme depression, took a quantity of hydrocyanic acid, from the effects of which he speedily died. The matter remains under investigation at present; but so strongly has popular indignation been aroused against Dr. Whitmarsh, that he has been compelled to leave the neighbourhood of Hounslow for a while, attempts having already been made to wreck his dwelling by an infuriated mob. Dr. Edwardes was greatly liked by the people among whom his practice lay; and it is difficult to conceive that he could have been guilty of so serious an indiscretion as that imputed to him.

Is it Possible to Grow Giants?

THIS question has received almost a solution. According to the *New York Times*, the incubator of M. Tarnier has succeeded in raising infants who, at the end of six months, weigh 84 lbs., and whose weight at birth six months previously was only 10 or 12 lbs. The incubator of M. Tarnier is framed on the model of the one for hatching eggs scientifically. The immense success which attended the artificial incubation of chickens in France attracted the attention of the learned, ingenious, and obstetric physician. He was attached to a hospital for foundlings, and although the position gave him an admirable opportunity for experimenting with new medicines, he was a humane man, and he was annoyed at the large number of foundlings who died within the first six months of their life. The majority of those admitted to the hospital were weak and sickly, but in that respect they did not differ from all sorts of French infants. Dr. Tarnier felt that it was a reproach to medical science that French infants could not be cultivated with as much success as French chickens, and he resolved to try what artificial incubation, if it so may be called, would accomplish if applied to infants.

The doctor constructed a child-incubator on precisely the model of the ordinary chicken-incubator. It was a

box, covered with a glass side, furnished with a soft woollen bed, and kept at a temperature of 85 degrees Fah. by the aid of hot water. He selected as the subject of his first experiment a miserably-made infant—one, in fact, that had rashly insisted upon beginning the world at an injudiciously early period. This infant was placed in the incubator, provided with a nursing bottle, and kept in a dark room. To the surprise of the doctor, he ceased to cry on the second day after he was placed in the incubator, and although it had previously been a preternaturally sleepless child, it sank into a quiet, deep sleep. The child remained in the incubator for about eight weeks, during which time it never once cried, and never remained awake except when taking nourishment. It grew rapidly, and when at the expiration of sixty days it was removed from the incubator, it presented the appearance of a healthy child of a year old. Delighted with the success of this experiment, Dr. Tarnier next selected an ordinary six months old infant addicted to the usual pains and colic, and exhibiting the usual fretfulness of French infants. This child conducted itself while in the incubator precisely as its predecessor had done. It never cried; it spent its whole time in sleep; and it grew as if it had made up its mind to embrace the career of a professional giant. After six weeks' stay in the incubator, it was removed and weighed. During this brief period it had doubled its weight. It had become so strong and healthy that it resembled a child three years old, and it could actually walk when holding on to a convenient piece of furniture.

These two experiments satisfied Dr. Tarnier of the vast advantages of artificial child-incubation. He immediately proceeded, with the permission of the authorities of the hospital, to construct an incubator of the capacity of 400 children, and in this he placed every one of the 360 infants who were in the hospital on the 10th day of February last. With the exception of one who died from congenital hydrocephalus, and another who was claimed by its repentant parents, the infants were kept continuously in the incubator for six months, when they were removed in consequence of having outgrown their narrow beds. The result will seem almost incredible to persons who are unfamiliar with the reputation of Dr. Tarnier, and have not seen the report made to the French Government by a select committee of twelve.

The average age of the infants last February was eight months and three days, the youngest being less than twelve hours old, and the eldest not more than eleven months. Their average weight was 10 lbs., only one of the entire 360 having attained a weight of 32 lbs. At the end of six months of artificial incubation the average weight of each infant was 84 lbs., and there was not one who would not have been supposed by a casual observer to be at least eight years old. In other wards, six months of artificial incubation did as much in the way of developing Dr. Tarnier's foundlings as eight years of ordinary life would have done. The infants were strong and healthy, as well as big; they walked within a week of leaving the incubator, and most of them have since learnt to talk. These results surpassed Dr. Tarnier's most enthusiastic expectations, and there can be no doubt that his system of artificial child-incubation will be adopted

not only in every child's hospital in France, but in every private family throughout the civilised world. We must make allowances for some of the statements, which are taken from an American paper. Allowing for exaggerations, the incubator of Tarnier may be of use in rearing delicate and premature infants. It is an ingenious application of a principle recognised by agriculturists.

Oleoresin of Male Fern: increasing its Efficacy against Tape-worm.

ACCORDING to E. Dieterich, the frequent failure of oleoresin of male fern as a remedy against tape-worm is to be ascribed to its irrational administration. It has become known that the popular "worm-doctors," who use almost exclusively the oleoresin of male fern, and who hardly ever meet with a failure, administer the remedy in conjunction with castor-oil, instead of following it by the oil after one or two hours, as is usually done by practitioners. The object is to bring the extract in an unaltered or undigested condition into contact with the worm. The experiments which have been made by mixing one part of the oleoresin with two parts of castor-oil have been very successful, and this mode of administration deserves, therefore, the preference. Oleoresin of male fern is apt to derange the stomach, and, when enveloped partly in the oil, is likely to pass it more rapidly, which constitutes another advantage. The mixture has, it is true, an unpleasant taste. This may, however, be disguised by filling it in capsules of about 45 grains each. The dose may be regulated for six capsules to seven or eight more, according to circumstances. It is advisable to empty the bowels the preceding day by a mild purgative, best by castor-oil.

The King and Queen's College of Physicians.

THE following examiners have been appointed by the President of this College, Dr. William Moore, from among the Censors and Fellows, for the membership of the College, and for the certificate in sanitary science during the ensuing year:—For the Membership: 1. Principles of Medicine, including Pathology, Medical Anatomy, and Medical Chemistry—Drs. Finny and Purser; 2. Practice of Medicine, including Principles of Public Health—Drs. Cruise (Vice-President) and Duffey; 3. Clinical Medicine—Drs. Foot and Nixon. For the Certificate in Sanitary Science: 1. Etiology and Prevention of Disease—Dr. Cruise (Vice-President); 2. Chemistry—Dr. Walter Smith; 3. Meteorology, Climatology, and Vital Statistics—Dr. Quinlan. The names of the gentlemen appointed to examine in engineering and in sanitary law have already been published. Examinations will be held for both the membership and for the sanitary certificate in January.

WE understand that the subscriptions for the memorial to the late Sir C. Wyville Thomson have reached a total of 500 guineas. It has been decided that a bust, by Mr. J. T. Hutchinson, R.S.A., shall be placed in the University Hall, Edinburgh, and that the balance of the fund shall be devoted to putting a stained-glass window in the church of St. Michael, Linlithgow.

Treatment of Diphtheria by Chinoline.

SOME excellent results appear to have been obtained by Dr. Seifert (*Berl. klein. Woch.*). Dr. Seifert prefers the pure chinoline to the tartrates, on account of the bad taste and smell of the latter. The chinoline is prescribed in a 5 per cent. solution for painting the fauces, the solvent being a mixture of equal parts of alcohol and water. A new brush of hair or cotton wool is used each time, the old ones being burned. The stinging pain at first produced is succeeded by a sense of comfort and by the ability to swallow, if the throat is washed out with cold water after being painted. The following formula is the one which is prescribed for a gargle:—Pure chinoline 1 gram, distilled water 500 grams, sp. vini rect. 50 grams, and menth. pip. gtt. ij.

The Adulteration Law in New York.

THE State Board of Health of New York have commenced prosecutions under the new adulteration law by causing the arrest of nine persons for selling cream of tartar which was adulterated with ground gypsum. The accused pleaded "not guilty," but were held in 100 dol. bail each for trial. The adulteration in these cases amounted to from 37 to 92 per cent. of terra alba, or ground gypsum. In every case the accused stated that the substance had been purchased for pure cream of tartar, and he did not know that it was adulterated.

The Cholera.

ACCORDING to the *Veröffentlichungen des Deutsches Gesundheitsamtes* for December 18, the number of deaths from cholera at Mecca, from October 24 to November 6, amounted to 290. The disease has now ceased. In Japan, between April 28 and October 5, there occurred 47,089 cases, with 27,757 (58·2 per cent.) deaths. In the capital, Tokio, there were 6,499 cases, with 5,031 deaths. In French Cochinchina the disease has nearly ceased since the middle of October.

Royal Medical Benevolent Fund Society of Ireland.

DR. J. MAGEE FINNY has been elected an honorary secretary of this fund, in the place of Mr. A. H. Benson, appointed acting secretary, in place of Dr. Marks, resigned. Dr. Finny was for several years honorary treasurer of the fund, and is thoroughly acquainted with its working.

Disinfecting Iodoform.

THE *Journal de Thérapeutique* reports that Dr. Yvon effects the abolition of the smell of iodoform by the very simple procedure of incorporating with it a little essence of roses. Half a drop of the essence removes the odour of sixty grammes of iodoform, the compound retaining that of the essence.

THE appointment of Physician-in-Ordinary to Her Majesty the Queen, vacant through the death of Sir Thomas Watson, has been conferred upon Dr. Wilson Fox, Physician to University College Hospital.

Harveian Society of London.

At the annual meeting of this Society, to be held on January 18th, the election of office-bearers for the ensuing year will take place, after which the President will deliver an address, and a *conversazione* will close the proceedings. The following is a list of the names proposed by the Council as officers of the Society for the year 1883:—President: E. Symes Thompson, M.D. Vice-Presidents: W. B. Cheadle, M.D.; H. Cripps Lawrence, L.R.C.P. Lond.; C. P. Field, M.R.C.S.; Percy Boulton, M.D. Treasurer: Thomas Buzzard, M.D. Hon. Secretaries: W. H. Lamb, M.B.; J. Ernest Lane, M.R.C.S. Council: Henry Power, F.R.C.S.; D. Ferrier, M.D.; J. Knowsley Thornton, M.B. Ed.; H. W. Kiallmark, M.R.C.S.; J. H. P. Staples, M.D.; H. Allen Aldred, M.D.; W. Hickman, M.B.; S. H. Davson, M.D.; W. R. Gowers, M.D.; Charles Vasey, L.F.P.S. Glasg.; James E. Pollock, M.D.; Malcolm Morris, F.R.C.S.E.

THE scientific world and the many friends of Professor Owen will be sorry to learn that the state of his health is such as to cause great anxiety.

DR. J. OWEN REES, late Senior Physician to Guy's Hospital, has been appointed Physician-Extraordinary to Her Majesty the Queen, in succession to Dr. Wilson Fox, appointed Physician-in-Ordinary.

HER Majesty the Queen has expressed her interest in the efforts now being made to provide fully-qualified medical women for India, and gladly countenances a proposal suggested by Mr. Keltridge, of Bombay, to raise, with the co-operation of natives of India, a guarantee fund for the benefit of women doctors willing to go out from this country to settle in India.

It is understood that the Secretary of State for War has approved the appointment of Deputy Surgeon-General J. A. Marston, M.D., C.B., lately employed as Sanitary Officer of the Egyptian Expedition, to be chief of the Sanitary and Statistical Branch of the Army Medical Department at the War Office, vice Deputy Surgeon-General J. Irvine, M.D., who has been selected to succeed Surgeon-General Sir James Hanbury, K.C.B., in medical charge of the Army of Occupation in Egypt.

THE annual rates of mortality last week in the principal large towns of England and Wales averaged 24.9 per 1,000 of their aggregate population, and were as follow:—Portsmouth 16, Brighton 17, Leicester 19, Salford, Bristol, Derby 20, Wolverhampton, Hull 21, Bolton, Norwich, Birkenhead 22, London 23, Sheffield, Blackburn, Bradford, 24, Huddersfield, Cardiff 25, Oldham, Birmingham, Newcastle-on-Tyne 26, Leeds, Halifax 27, Plymouth 28, Nottingham, Manchester 29, Preston 33, Liverpool 35, and Sunderland 37. No returns for the week were received by the Registrar-General from Dublin, Edinburgh, or Glasgow.

THE highest annual death-rates per 1,000 in the twenty-eight large towns last week from diseases of the zymotic class were—From whooping-cough, 2.1 in Ply-

mouth and 2.7 in Preston; from measles, 1.2 in Birkenhead and in Cardiff and 3.1 in Sunderland; from scarlet fever, 1.3 in Sunderland and 1.6 in Nottingham; and from "fever," 2.2 in Liverpool and 3.5 in Sunderland. The 17 deaths from diphtheria in the twenty-eight towns included 12 in London and 3 in Manchester. Small-pox caused 2 deaths in London, 2 in Newcastle-upon-Tyne, one in Nottingham, and one in Sunderland.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

A "POOR PROFESSION."—A parish appointment is now vacant in Edinburgh for which there is the usual scramble. Printed testimonials recounting the mighty works and honours of the applicants are being circulated in all directions. The whole performance would be ludicrous if it were not sad to think that professional men are obliged to struggle so fiercely for existence. The coveted prize of £60 per annum for attending the poor in some of the worst alms of Edinburgh will probably fall to the candidate who is the son of some tradesman on the Town Council, or who has married the daughter of some Free Kirk minister.

NURSES' MEETING AT THE GLASGOW ROYAL INFIRMARY.—On New Year's Day an interesting meeting of the nurses of the institution took place at the Royal Infirmary, Glasgow. The Hon. the Lord Provost presided, and was accompanied to the platform by Sir James Watson, Sir William Collins, Dr. Scott Orr, Eben Watson, &c. The Lord Provost briefly opened the proceedings by an introductory address, and Dr. Scott Orr delivered a special address to the nurses, in which, having contrasted the nursing of past years with the system at present in operation, he went on to speak of some of the characteristics and qualifications of a trained nurse. This address, which was an interesting and instructive one, was followed by a statistical account of the working of the Infirmary during the year by Mr. McEwen.

THE HEALTH OF GLASGOW.—DR. RUSSELL'S REPORT.—At the meeting of the Glasgow Town Council, held on the 2nd inst., Dr. Russell submitted his usual fortnightly report, in which he stated that the death-rate in the first week of the fortnight was 35. The number of deaths from infectious diseases of children was 104 in place of 67—viz., 52 from whooping-cough, 32 from scarlet fever, and 20 from measles. There have not been so many deaths from scarlet fever since the autumn of 1880, or from whooping-cough since the spring of the same year. Of the total fatal cases of scarlet fever, 22 have occurred in the Eastern district. The past fortnight has been marked by that extraordinary mortality which always accompanies cold in Glasgow, and to which, if the cold continues long enough, and especially if it be accompanied by fog, there scarcely seems any limit. On the present occasion the frost was of short duration, and the fog, though continuous during most of the week preceding, was never so dense as in 1874-75. It is quite certain, however, that if we happen upon a frost lasting as long, and a fog as dense, the experience of that winter will be repeated. It is worth noting that the phenomenal and startling death-rates of Glasgow have never arisen from epidemic disease, at least during the last twenty years, but from cold, and that the very highest arose from the accumulation over us of our smoke in the foggy calm of continuous frost. The number of cases of fever registered was 40 in place of 41—

viz., 31 of enteric fever, 8 of typhus, and 1 undefined. There were 184 cases of measles, 172 of scarlet fever, 72 of whooping-cough, and 21 of diphtheria registered, of which 51 were removed to hospital, and the remainder treated at home.

BUSBY.—A fatal case of typhoid fever has occurred in this village. As there is no other case in the meantime, it is hoped that the fever will go no further. The new water supply has greatly improved the sanitary condition of the place.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 30th ult., the mortality in Edinburgh was 100, and the death-rate 23 per 1,000. There were 15 deaths under one year, and 28 above 60, of which 6 were above 80, and 3 above 90 years. Diseases of the chest accounted for 58 deaths, and zymotic causes for 9, of which 3 were due to fever, 3 to scarlatina, and 1 to measles, the intimations of these diseases being 6, 31, and 7.

THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES IN EDINBURGH.—At a meeting of the Public Health Committee of Edinburgh Town Council, held on the 2nd inst., Dr. Littlejohn, Medical Officer of Health for the city, submitted a report bearing on the compulsory notification of infectious diseases. From this it appeared that the number of intimations by medical practitioners during the month of December was 366, of which 157 were from the New Town, 146 from the Old Town, and 63 from the southern suburbs. The report also stated that the total number of intimations for last year was 7,063, comprising 2,477 from the New Town, 3,599 from the Old Town, and 1,072 from the southern suburbs. In not one of these instances had it been found necessary to use the compulsory powers conferred upon the authorities by the Act of Parliament of removing the patient to an hospital. The fees paid to medical practitioners for the notifications made during the past year amounted to £882 17s. 6d.

THE ROYAL INFIRMARY, EDINBURGH.—The annual meeting of the contributors to this institution was held last week, from the report of which we gather the following important items:—Patients admitted between 1st October, 1881, and 1st October, 1882, 5,949—6,443. Of these there were dismissed cured, 3,184; dismissed relieved, 1,824; dismissed on other grounds, 418; died in the hospital, 501—5,945; patients remaining at 1st October, 1882, 498. Of the cases brought to a termination during the year, 568 were cases of infectious disease treated in the fever house in the old Infirmary, including 190 cases of scarlet fever; 2,385 were ordinary medical cases, and 3,042 were surgical cases. The daily average number of patients in the hospital during the year was 537; the greatest number at any one period was 578, the lowest 477, and the average time during which each patient remained under treatment was 30·4 days. The extraordinary income—that is, receipts from donations and legacies above £100—amounted to £21,337 2s. 11d., as compared with £6,572 3s. 7d. for the preceding year, showing an increase of £14,764 19s. 1d., while the extraordinary expenditure has been £1,081 9s. 8d. The ordinary expenditure of the Infirmary for the past year was £31,286 10s. 4d., as against £31,720 16s. 8d. for the preceding year, showing a decrease of £434 6s. 4d. We may state that the Infirmary is still heavily weighted with debt, and that subscriptions are urgently needed.

UNIVERSITY OF EDINBURGH.—The register of the General Council of this University has now been made up. During the year 318 members have been registered, and 101 have been struck off as dead. The number of members on the register is 4,742, being an increase of 217.

Literature.

THE SIMPLICITY OF LIFE. (a)

DR. RICHARDSON is not satisfied with the critiques which, at the time, appeared on his work on "The Simplicity of Life." Very many writers are in much the same predicament, but they do not all rush into print, as he has done, to review the reviewers. But as it so happens a great deal of what Dr. Richardson has to say in his critique is very true, albeit he presents a very unsatisfactory picture of the present state of medical science. For example, he says: "Writers of great authority are not ashamed to indicate a chemical theory for one disease, a vital theory for a second, a neurotic theory for a third, and even a mechanical theory for some other disorder." All this is very sad. He says other hard things about the fallacies of the faculty, and evidently "fears not the anger of the wise to raise," as he himself states in the couplet with which his *brochure* concludes.

CLIMATE AND FEVERS IN INDIA.

THE recently published work on "Climate and Fevers in India," by Sir Joseph Fayrer, valuable and important as it would be at any time, is especially so at present, when the lessons inculcated therein may and ought to be applied in reference to the same great class of disease by which so many of our troops in Egypt are being struck down. In that work an exhaustive description is given of the several types of fever met with in India, and indeed in the tropics generally. Adverting, however, to the particular type of fever which, according to official nomenclature, at present affects our troops at Cairo, it is desirable to collate some such particulars as may throw some light upon the etiology of that form of the disease. This the work in hand enables us readily to do. The author observes (p. 191) that Dr. Parkes entertained doubts that the generally accepted cause of enteric fever is the only one to which that disease is to be referred. Dr. Bryden believed that the typhoid fever of the British soldier in India is primarily due to climatic influences; that the belief that defective conservancy will be found in every case where typhoid fever shows itself is a narrow view, and not warranted by any feature in the aspect of typhoid as we meet with it among our soldiers. It is added (p. 192), "If enteric fever were in India as it undoubtedly is in Europe, due to faecal emanations, how can we explain the circumstances that in the midst of the city of Dacca, containing, as it did in 1872, 69,000 inhabitants, densely populated quarters are to be seen, in which the faecal deposits of generations are collected in unsightly heaps, or thrown into privy wells within a few feet of the well from which drinking-water is obtained, which causes diarrhoea when first used, but never any form of fever is observed." These remarks are commended to the especial attention of the medical officers now contending against fever and other endemic diseases among our troops in Egypt, and it will be for them to say how far the results of their observations may be to confirm the statement quoted that the merely pythogenic view of its causation "is a narrow view." Sir Joseph Fayrer enters fully into the several points on the subject of fever as met with in tropical countries, in regard to which differences of opinion exist. These opinions he has carefully analysed, with the result that no reader can rise from a perusal of his work without having the strong conviction that theories formed from conditions as they are met with in London are, in very many instances, forcibly applied in countries and under circumstances to which they are palpably unsuited. There is indeed much reason to believe that, as a result of this misapplication of home-born theories, the labours of such men as Twining, Annesley, and Martin have, for the time being, been obscured. This circumstance does not escape the notice of Sir Joseph Fayrer. Thus (p. 164) he observes: "Writers on Indian and tropical disease have described a form of continued fever liable, like remittent, to be modified by visceral complications, and to have a fatal termination, post-mortem examination revealing pathological changes of various degrees of importance. It is attributed to climatic causes, and the circumstances attending life in tropical or sub-tropical regions, such as heat, atmo-

(a) "The Simplicity of Life." A Critique on Criticism. By B. Richardson, M.D., M.A., T.C. Dub. London: H. K. Lewis. 1882.
(b) "Climate and Fevers of India." By Sir Joseph Fayrer, K.C.S.I., LL.D., M.D., F.R.S., &c. London: J. and A. Churchill. 1882.

spheric vicissitudes, terrestrial emanations, personal habits. But it is necessary to distinguish it from specific fevers, with which it may be confounded." Just so. And there is reason to believe that it very often is thus confounded, the consequences of its being so by no means satisfactory. Every medical officer is, or about to proceed to, India or the tropics should carefully study for himself this extremely important work.

THE CONTAGIOUSNESS OF PULMONARY CONSUMPTION AND ITS ANTISEPTIC TREATMENT. (a)

WHATEVER may be said in the present day of micro-organisms and tubercle bacilli as active agents in the origin and spread of tuberculous diseases, the experience of those who have passed many years in the observation of consumptive people is antagonistic to any belief in the disease being of a contagious nature. The extensive and carefully worked-out statistics of Dr. C. T. Williams, derived from his vast experience at the Brompton Hospital, are in contradiction to any theories that may have been formed as to consumption being a contagious disease.

The conditions of inoculation under which a true tuberculating process may be set up in an animal, are concisely and ably set forth by Dr. Burney Yeo in his recapitulation of the careful and important experiments of Dr. Hippolyte Martin, of Paris; and Koch's demonstration of the "virus" of tubercle in the form of tubercle-bacillus is aptly put in just at the point where such a link in the chain of evidence is wanting to mark the distinction between tuberculating and non-tuberculating processes of disease. It is well known that in Southern Europe consumption is a most virulent disease, and regarded as contagious in its nature. Dr. Yeo very reasonably suggests that this may be due to the relatively higher temperature of Southern Europe, "and we naturally associate with this reflection Koch's statement that the tubercle-bacillus requires a temperature above 86° Fahr. for its propagation" (page 32). In our own experience we have often remarked, especially among poor persons confined to one hot close room, to what an active and destructive form pulmonary consumption can be brought by this kind of "cultivation." To study tubercular phthisis in its most virulent form, the patient should be confined in one atmosphere, all windows must be kept carefully closed, and, if this produce weakness and depression, let this state be met by the frequent administration of port wine, rum, brandy, or, indeed, any form of alcohol. The cough will probably be severe and distressing, and much opiated cough medicine will be needed to impose silence on this noisy cough. One cannot but think of the possibility of a second individual shut up much with such a case as that just described running some risk of tubercle, but we are unable to recall any facts in proof of such event actually coming under notice.

The practical part of Dr. Yeo's book is found in Lecture II., on "The Antiseptic Treatment of Pulmonary Consumption," and here the infective bacillus theory works in well. What can be more rational or sound practice than to destroy these bacilli by surrounding them with an antiseptic vapour? Some very good illustrations are given of the efficacy of antiseptic inhalations of creasote, eucalyptol, and other agents of less utility. It is well known that the antiseptic method is making much progress and producing excellent results upon patients. Instead of the patient having to encounter the fatigue and weariness of a long journey to some foreign health resort, where his case may be at once settled by an attack of typhoid fever acquired soon after his arrival, he now has the antiseptic climate brought literally under his very nose, and thus the rich and the poor are pretty evenly started in the race for health.

Much may be learned by the perusal of Dr. Burney Yeo's interesting lectures. A good summary of the condition of our present knowledge of tubercle-bacillus is given, and the practical physician will fully appreciate the lecture on the method of using antiseptic inhalations.

(a) "The Contagiousness of Pulmonary Consumption and its Antiseptic Treatment." Two lectures delivered in King's College Hospital in the Summer Session of 1882, with Appendices and Notes. By J. Burney Yeo, M.D., F.R.C.P., Physician to King's College Hospital; Fellow of King's College; late Senior Assistant Physician to the Brompton Consumption Hospital. London: J. and A. Churchill, New Burlington Street. 1882. Pp. 124.

ATLAS OF SKIN DISEASES. (a)

It is nearly five years since this Society ceased to publish their most valuable "Dermatological Atlas;" and this circumstance, coupled with the beginning of their splendid "Pathological Atlas," caused most of the outside medical public to consider the issue at an end. This circumstance was regretted, as the subject was evidently not quite exhausted. The former of the two Fasciculi now before us illustrates hæmorrhagic purpura, and the latter molluscum contagiosum. Both pictures are admirably coloured to life, and combine great pathological exactness with high artistic finish. We trust that the series may be further extended from time to time, and that some of the rarer skin diseases described by Mr. Hutchinson in his lectures on clinical surgery may be included.

Correspondence.

A VACCINATION CONFERENCE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having paid considerable attention to the subject of vaccination, I intend organising a conference, to meet in London in the early part of April, to discuss the merits and demerits of the practice, and the question of its compulsory enforcement. It is hoped that, as the inquiry will be unfettered by officialism, an independent and reliable verdict upon this much-vexed question will be thereby returned to the public. With a view to assist the work of the forthcoming conference, I am forwarding the accompanying series of questions to leading medical men and those well informed upon the subject, and I beg to request that they will do me the favour to reply to them before the 1st of February.

I am, Sir, yours, &c.,

M. D. MAKUNA, M.R.C.S., L.R.C.P.
(Late Medical Superintendent of Fulham Small-Pox Hospital).

Questions.

1. What are your views regarding compulsory vaccination in England, Scotland, or Ireland?
2. What are your views regarding the protection afforded by vaccination against small-pox?
3. What diseases have you, in your experience, known to be conveyed, or occasioned, or intensified by vaccination? Please give cases.
4. What opinion do you hold as to the quantity and quality of vaccination, as determined by the cicatrices?
5. What opinion do you hold as to the relative values of humanised and animal lymph, both as regards efficacy and safety?
6. What opinion do you hold regarding the relations subsisting between variola and vaccinia, and the theory of vaccination?
7. How far do you consider insanitary conditions responsible for small-pox epidemics, and how far can small-pox be controlled by improved sanitation?

[* * The foregoing letter and questions have been forwarded this week to about 3,000 public vaccinators in the United Kingdom, and to others who have taken special interest in the subject; but as it was impossible to post a copy to every member of the profession, the author will be equally thankful of replies from those who have not received the same, and who read it for the first time in the columns of the *Medical Press*. The object has our warmest sympathy.—ED.]

Notices to Correspondents.

Correspondents requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

(a) "Atlas of Skin Diseases." Published by the New Sydenham Society. Fasciculi 45 and 46. London: H. K. Lewis. 1882.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

DR. HERCULES MACDONALD.—Your paper on "The Electrical Treatment of Enlarged Glands" shall appear in our next.

DR. BALMANGO SQUIRE.—As your communication "On a New Kind of Urthral Syringe" has already appeared in several journals, pressure on our space with original matter precludes its insertion in the columns of the *Medical Press*.

MR. FRY.—Several cases have been recorded during the year, but not all of them were successful. The abdominal method of operating was introduced by Langenbuch, not Langenbeck.

RUSTICUS.—Constipation should yield under a course of rational treatment regularly pursued. Sir George Burrows has recommended the following pills, one every third night:—

℞ Podophyll resinæ, gr. i.;
Pil. rhel. co., gr. x.;
Ext. hyocyami, gr. iv.

Divide into four pills.

CUM LABORE.—We have no knowledge of any publication such as you describe. There are numerous journals devoted to the discussion of practical sanitation, and you will probably find any one of them suitable. A medical paper is scarcely the place for such information, useful though it undoubtedly is.

MR. GREGSON.—It would be very inexpedient.

W. S.—Ringworm can only be got rid of by vigorous measures. Whatever the mode of treatment you adopt, let it be thorough of its kind, and you may anticipate a favourable result. Dr. Living's little book, or Mr. Morris's, is very good.

A JUNIOR STUDENT.—You will do best for yourself by following the advice given by your teachers. We cannot, in the face of their recommendation, suggest any alteration in the list you have given; moreover the works named are both reliable and complete.

TREATMENT OF OBESITY—A FRENCH STORY.—The *Vichy Journal* is accountable for the following story. We suppress names:—About four years ago T. N. was condemned to five years' imprisonment for debt by the Lord Mayor, and sent to Clerkenwell to complete his sentence. At first T. N. was depressed, then he consoled himself, took to his bed, and to eating. He ate and slept, took exercise in his cell. After three years' eating and sleeping he thought he would like some fresh air. He had, however, become so stout that he could not pass out through the door of his cell; neither sideways nor in any position could this be accomplished. At this period his family decided on paying his debts and restoring him to liberty. This was impossible. He could not get out. The cell could not be broken down, as in England it is not allowed to destroy the property of the Queen. The unfortunate T. N. would have remained a prisoner for life, but fortunately a French paper fell under his eyes. This journal told of the marvellous cures wrought by the waters at Vichy:—the fat man became lean; the most enormous mountains of adipose tissue disappeared after a course of these waters. Happy release for him. He ordered twenty gross of these waters. In two months' time he was so reduced that he could have stepped through a one-foot ring. He left his cell and Clerkenwell singing the praises of the waters of Vichy.

DR. CUNNINGHAM.—Received with thanks.

MR. W. COLLINGS.—*Lippia Meziaca* is an expectorant recently introduced by Dr. Saxton, of Baltimore. It is given in 1 and 1½ fluid drachm doses, and is said to combine valuable demulcent as well as expectorant properties. We have had no personal experience of the drug, but the article of Dr. Saxton should induce trials.

A GOVERNOR.—The adjourned meeting will be held to-day (Wednesday), and needs all the support which those who have the welfare of the institution at heart can and should accord.

CLEANLINESS VERSUS DEATH.—At the recent Medical Congress at Seville, Spain, Dr. Robert said that the death-rate of Madrid was 400 per 1,000. This excessive death-rate he ascribes to two factors—the want of the use of water, and poor alimentation. There are thousands of Spaniards who have never washed since they were born.

DR. JENNER addressed the following lines to a lady upon the recovery of her daughter, which, sent with a pair of ducks, afford a specimen of his facetious vein:—

"I've despatched, my dear madam, this scrap of a letter,
To say that Miss — is very much better;
A regular doctor no longer she lacks,
And therefore I've sent her a couple of quacks."

INDIGNANT.—Sir Henry Thompson would probably be equally indignant were it supposed that such an arrant puff originated with him. We agree with you that "the skillfully and successfully-performed operation" thus reported of a private patient in the lay public press is in bad taste; but, from what we know of Sir Henry Thompson, we are certain he would not be a party to such publication. It is another of the many illustrations which suggest deliverance "from our friends."

MEETINGS OF THE SOCIETIES.

HUNTERIAN SOCIETY.—This evening (Wednesday), at 7.30 o'clock Council Meeting.—8 o'clock, Dr. Charleswood Turner will show a Heart of Two Cavities.—Mr. T. McCarthy, "On Cases of Fracture of the Skull."

CLINICAL SOCIETY OF LONDON.—Annual General Meeting, Friday, Jan. 12th, at 8.30 p.m., Report of Council; Election of Officers and Council, 1887.—Dr. Coxwell, "On the Case of a Child with Symptoms resembling those of Myxœdema."—Dr. Davies-Coiley, "On a Case of Enormous Enlargement of the Lower Lip caused by Operation."—Dr. Southey, "On Tacheté and Symmetrical Gangrene."

OBSTETRICAL SOCIETY OF LONDON.—This evening (Wednesday), at 8 p.m., Specimens will be shown.—Mr. Knowsley Thornton, "On a Case of Extirpation of Uterus and Appendages for Epithelioma of the Cavity."—Mr. W. S. A. Griffith, "On Notes of a Specimen of Ante-

flexion of the Uterus."—Mr. C. E. Jennings, "On Transfusion."—Dr. Galabin, "On Notes of Two Cases of Transfusion of Blood."

ROYAL MICROSCOPICAL SOCIETY.—This evening (Wednesday), at 8 p.m., Mr. A. D. Michael, "On Notes on the Anatomy of the Oribatida."

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Thursday, Jan. 11th, at 8.30 p.m., Mr. Priestley Smith, "On the Growth of the Crystalline Lens."—Mr. David Lees, "On a Case of Paralysis of Third Nerve in a Child."—Dr. Abercrombie, "On a Case of Paralysis of Sixth Nerve in a Child."—Dr. Hughlings-Jackson, "On the Movements of the Eyes in a Case of Ear Disease."—Dr. E. Maddox (communicated by Dr. Greenfield), "On a New Method of Determining the Relation between Convergence and Accommodation."—Mr. Rockliffe, "On a Case of Epithelial Tumour growing from a Hair in the Anterior Chamber."—Living Specimens at 8 o'clock.

EDINBURGH OBSTETRICAL SOCIETY.—This (Wednesday) evening, at 8 p.m., the following papers will be read:—Dr. J. Halliday Croom, "Observations on the Bladder during the Puerperium."—Dr. A. D. L. Napier, "Umbilical Cord round Child's Neck as a Cause of Delayed Labour, and sometimes a Cause of Death."—Professor Simpson, "Case of Basilius."

Vacancies.

Bromyard Union.—Workhouse Medical Officer. Applications to be sent to the Clerk on or before Jan. 22nd.

Bromyard Union.—District Medical Officer. Salary, £105, with fees extra. Applications to be sent to the Clerk on or before Jan. 22nd.

Chorlton Union.—Assistant to the Resident Medical Officer. Salary, £120, with furnished apartments, &c. Applications to be sent to the Clerk to the Guardians not later than Jan. 24th.

Leicester Infirmary and Fever House.—House Surgeon. Salary, £120 for the first year, rising at the rate of £10 per annum until the fourth year, with board, &c. Applications to be addressed to the Secretary on or before Jan. 15th.

London Lock Hospital.—House Surgeon. Salary, £50, with board and residence. Applications to be sent to the Secretary on or before Jan. 23rd.

Appointments.

BEEVOR, H., M.R.C.S., Assistant House Physician to King's College Hospital.

EDWARDS, A. R., M.R.C.S., House Surgeon to King's College Hospital. KERSHAW, H., L.R.C.P. Ed., M.R.C.S., Resident Medical Officer to the Leeds Public Dispensary.

MAQUIRE, R., M.D. Lond., Pathological Registrar to the Manchester Royal Infirmary.

MCGILL, A. F., F.R.C.S., Honorary Assistant Surgeon to the Leeds General Infirmary.

MOODY, J. M., L.R.C.P. Ed., M.R.C.S., Medical Superintendent of the Additional Asylum for the County of Surrey, Coulsdon.

PORTER, G. D., M.R.C.S., Assistant House Surgeon to King's College Hospital.

ROBSON, A. W. M., F.R.C.S., Honorary Assistant Surgeon to the Leeds General Infirmary.

SERJEANT, G., M.R.C.S., Medical Officer for the Sixth District and the Workhouse of the Launceston Union.

STEVENS, B. L., M.R.C.S., House Accoucheur to King's College Hospital.

TYNAM, R. G., M.R.C.S., House Surgeon to King's College Hospital.

WEST, J. A., M.R.C.S., House Surgeon to the North-Eastern Hospital for Children.

YOUNG, A. H., F.R.C.S. Eng., M.B. Edin., Medical and Surgical Registrar to the Manchester Royal Infirmary.

Births.

ADAM.—Jan. 4th, at Crichton House, Dumfries, N.B., the wife of James Adam, M.D., of a daughter.

BERRY.—Jan. 5th, at Appleton Cottage, Great George Street, Wigan, the wife of Wm. Berry, M.R.C.S. Eng. and L.R.C.P. & S. Ed., of a son.

LENTAIGNE.—Dec. 31st, at 29 Westland Row, Dublin, the wife of John V. Lentaigne, B.A., T.C.D., L.K.Q.C.P., of a daughter.

MOIR.—Jan. 3rd, at Nevis Bank, Fort William, N.B., the wife of W. Brown Moir, M.D., C.M., L.R.C.S. Ed., of a son.

ROBSON.—Dec. 31st, at 20 South Street, Durham, the wife of E. Shedden Robson, B.A., M.R.C.S.E., of a daughter.

Deaths.

BARRATT.—Dec. 26th, at Ditchling Rise, late of Brighton, Arthur Newton Barratt, L.R.C.P. Ed., aged 42.

BIRT.—Jan. 4th, at Grove House, Leamington, Thomas Birt, M.D., aged 69.

CORNFOOT.—Dec. 26th, at Leven, Fife, N.B., James Cornfoot, M.D., late H.M.I.S., aged 78.

DAVISON.—Dec. 27th, at Hastings Cottage, Seaton Delaval, Northumberland, Anthony Davison, L.R.C.S. Ed.

EDWARDS.—Dec. 27th, at Hounslow, William Whitfield Edwards, M.D. Brux., M.R.C.S. Eng., son of Thomas Edwards, F.R.C.S. Eng., of Glascoed, Llanarthfrid, Montgomeryshire.

NICHOLS.—Jan. 1st, at the South Dublin Union, James's Street, Dr. John Moore Nichols, Resident Medical Officer, aged 85.

OTLEY.—Dec. 31st, at Ladbroke Grove, W., Drewry Otley, M.D., M.R.C.P., aged 79.

SNELL.—Jan. 2nd, at Cazenove Road, Stamford Hill, Edward Snell, M.R.C.S., aged 70.

VAUDIN.—Jan. 1st, suddenly, at Beaulieu, St. Peter's, Jersey, Charles Vaudin, Esq., M.R.C.S., aged 63.

WILSON.—Dec. 29th, at Redlands Bank, Holmwood, Surrey, James Arthur Wilson, M.D., at Consulting Physician to St. George's Hospital, aged 88.

The Lettsomian Lectures

ON

THE TREATMENT OF SOME OF THE FORMS OF VALVULAR DISEASE OF THE HEART. (a)

By A. ERNEST SANSOM, M.D., F.R.C.P. Lond., Physician to the London Hospital; Senior Physician to the North-Eastern Hospital for Children, &c.

LECTURE I.—ENDOCARDITIS.

The Rational Bases of Treatment—Morbid Anatomy—Clinical Investigation—Origin and Progress of Endocarditis—Study of Endocarditis occurring in Children—Pathogenesis—Existing Methods of Treatment—Preventive Treatment.

In my first perplexity as to choice of a subject when I earned that this Society had done me the high honour of electing me Lettsomian Lecturer for the present year, I thought that I ought to be guided by two considerations. The first, that it behoved me to give of my very best—in other words, that I should address you on a subject upon which I had the most personal experience. Yet I well knew that my best efforts would fall far short of my desire and your desert. The second, that considering the character and traditions of this Society, I should aim at something practically useful. I am very far from decrying the labours of those who pursue science for her own sake, and I well know that many who have so done have elicited results which have eclipsed, in numberless instances, in practical usefulness the results obtained by those who might, from their mode of procedure, be deemed more practical men. But I dared not take a narrow path in mere hope. So I thought it best to review a subject which presents itself frequently as a therapeutic problem to everyone who is daily occupied in the practice of medicine, and I chose the affections which my title indicates, because for many years my thoughts have turned towards them. It seemed to me that it might fulfil a useful purpose if I reviewed our extant knowledge as to the Treatment of Valvular Diseases of the Heart, compared these with the results of my own experi-

ence, and made, perhaps, a few suggestions as to progress towards precision in the future.

Then, as to the point of view whence I could review the subject, I felt some doubt. I could proceed from the therapeutic agent to the disease, or from the disease to the agent. Here, with all my difficulty as to how to perform my task, I could not hesitate as to how *not* to do it. I would by no means enunciate a therapeutic dogma, crystallize it into a phrase, and marshal the facts in such wise as they should support it, and if they refused, so much the worse for the facts. Apart from the consideration that such dicta as "similia similibus curantur," "contraria contrariis," &c., present to my mind some of the most pernicious of hasty generalisations of our day, is the one consideration that such therapeutic dogmas are based on the treatment of *symptoms*, and as I shall presently show that the diseases we are about to study are oftentimes accompanied by no symptoms at all, so the practical application of the dogma becomes an impossibility, and its universality an absurdity.

For many reasons I thought best to consider the phenomena of disease first, and our treatment of them subsequently. My plan then, will be to consider very briefly the basis on which I believe our therapeutics ought to rest. These are, in my opinion (1) the teachings of morbid anatomy; (2) clinical observation of disease-processes and their correlations, Then I propose to review (3) the lessons of the past as to treatment, and (4) to adduce towards the elucidation of the various problems the arguments from analogy afforded by experimental investigation—a mode of inquiry rendered difficult, alas, by the stumbling-blocks which a false sentimentalism has placed in our way.

First then, I will consider the teaching of morbid anatomy as to lesions of the valves of the heart. You will understand that I shall do this very briefly, for my object is merely to note them in so far as they may afford a guide to treatment, and when I speak apparently dogmatically I do not make an assertion "ex cathedra," but in the spirit of an inquirer after truth.

We will first consider the disease which most commonly affects the valvular apparatus of the heart and the adjacent endocardium in the disease known as *endocarditis*. In briefly reviewing its morbid anatomy much will remain unsaid, but I shall treat it first from the standpoint of mere observation, leaving all speculative questions. I would classify the first changes in the endocardium, which I shall notice as *exudative*. The curtains or cusps of the valves

(a) Delivered before the Medical Society of London, January 8th.

may be seen to be slightly swollen and the endocardium to contrast by its dulness with the healthy portions adjacent. But the changes are most noticeable at the free edges of the valves, where may be seen isolated or agglomerated bead-like processes. Upon such processes may be seen sometimes little caps of fibrine. A thin section of a valve thus affected is seen under the microscope to differ from healthy valve structure in that its cellular elements are more numerous, and especially towards the free edge are closely aggregated. I wish to insist on the fact that in a valve so affected, even the portions which seem to the naked eye unaffected are really infiltrated with cells. Only the aggregation is greater at the free edge. And here often the aggregated cells form little, very slight, concavities on which rest little caps of fibrine. The bead-like eminences observed by the naked eye are then, according to my view, indications of a more widely spread inflammatory change in the valve than might be at first suspected. My friend and colleague, Dr. Turner, will show some specimens illustrating this point. It is scarcely encroaching on speculation if we conclude that this is the recent, the early stage of endocarditis. In looking over the records of sixty-eight post-mortems of cases of valvular disease at the London Hospital, I find that this stage of recent inflammatory change with exudation was observed in nine, or about 13 per cent. The aortic cusps were affected in five, the mitral in three cases. In one case mitral aortic and tricuspid were affected. In another, mitral aortic, tricuspid, and pulmonic. In one case the tricuspid alone was thus diseased. In such early stages of endocarditis emboli were noted in two cases; in one in the kidney, in the other in a branch of the pulmonary artery.

The second form of endocarditis, or properly speaking valvulitis, to which I shall call attention is, that which I would term the sclerous or fibrotic form. Here the valve, and it is the mitral which is affected in by far the greatest frequency, is thickened; but the thickening is not due to swelling of the soft tissue. It is felt to be hard and firm. The endocardium of the auricle near to the valve is found to be dense and white. The valve-curtains, and often the cords and fleshy columns are more or less rigid. A patch of the endocardium lining the left ventricle and leading up towards the aortic cusps is sometimes also found white and thick, and the aortic valves themselves may be seen to have undergone similar changes. In this form microscopic investigation shows that there is a gradual fibrous transformation of the neoplasm resulting in the production of a quasi-cicatricial tissue. In some cases the thickening is such that the structure resembles cartilage. In fact, Dr. Wilks has found well-marked cartilage in such a thickened mitral, (a) or degeneration continuing, calcareous change may take place, and the valve, &c., become of bony hardness.

It is evident that this may be considered the chronic form of endocarditis. It was met with in one-fourth of the post-mortems in cases of heart disease which I have mentioned. The effects produced upon the mitral and aortic orifices will be treated of in future lectures. In this class of cases vegetations were observed in the proportion of 7 instances in 20 cases; on the mitral and adjacent auricle in 2 cases; the aortic in 2; the tricuspid, 3; the aortic, mitral, and tricuspid as well as in the auricle in one case. Infarcts were noticed in branches of the pulmonary artery (5 cases), spleen (5), kidneys (2), brain (1), retinal artery (1), intestine (1).

A third form of endocarditis, which I think of practical importance to distinguish, is that which is secondary to aortitis (atheroma). In this form it is the aortic valves which are affected in a large majority of instances. Patches of soft flabby swelling may be seen in the lining membrane of the aorta close to the aortic cusps, involving them in the change, and perhaps causing the inversion of one or more. Or yellowish patches may be observed, in some cases covered by a soft pulpy material, the blood, perhaps, forcing its way in some softened spot between or within the arterial coats. Or the coat of the aorta may be hard and thick, the thickening being of cartilaginous consistence; and in such thickening of the cusps of the valve may be involved. Or in like situation, and with like deformity of valves there may be a bony or stony hardness—a calcareous change. The evidence obtained by microscopical investigation is to the effect that, in the swollen soft patches are abundant exuda-

tive-cells with hyaline or slightly fibrillar matrix. These occur partly as swellings of the internal coat, but Dr. Wilks has observed them in all the coats of the vessel. The yellow patches show fat granules, and sometimes cholesterol crystals: there is evidently a fatty degeneration of the inflammatory neoplasm. In the fibrous or semi-cartilaginous variety there is more fibrillation and fewer cells, and in the hard and bony form there is a deposit of earthy salt in the interstices of the fibrous tissue. In this category came 27 of the 68 autopsies of heart disease which I have recorded. What I may term the soft stage was observed in 8 instances; fibrous thickening in 7; calcareous change in 5. The mitral valve was also thickened or atheromatous in 7 cases, the tricuspid in 2. In one case where there was calcareous transformation, ulceration of one cusp of the aortic valve was also observed. Infarcts were discovered in 3 cases—less commonly, it will be observed, than in the other forms of valvulitis—in the kidneys in one case, in spleen and kidneys in another, and in the middle cerebral artery in a third.

The fourth and last form of endocarditis, as demonstrated by post-mortem examination, to which I shall call attention is that termed ulcerative endocarditis. Swollen and flat portions of the endocardium of the valve may be seen to present here and there a yellowish or greyish discoloration, and to be covered by a finely granular debris. The superficial endocardium in such situations has become necrosed. Through such breach blood may find its way, and, extending between the layers constituting the valve, may form an aneurism thereof. Or the ulceration extending through both layers the valve may be perforated. More commonly, a considerable portion of the valve is eroded, and upon the eroded surface fibrine is deposited in the form of single or multiple vegetations. The finger readily detaches these vegetations, and the surface below them is found to be covered by a friable material. Such a specimen from a recent case under my care I now show you. Microscopic examination has demonstrated, in a very large number of cases, the presence on the ulcerated surface, and in the layers of the valve, of aggregated micrococci. Dr. Stephen Mackenzie exhibits here a specimen which shows these exceedingly well. In this form of valvulitis embolism is the rule, and such emboli are sometimes infective—that is, they may lead to suppuration, and the points whereat they lodge on may be causes of septicæmia. In the autopsies which I have taken as illustrative, ulceration was observed in 6, the ulceration affected the aortic valve in 3 cases, the mitral in 2, and both aortic and mitral in 1 case. Infarcts were observed in 5 out of the 6 cases, the exception being in a case included under the category of atheroma, where one of the aortic cusps was destroyed by ulceration, the others being thick and calcareous. The infarcts were found in the spleen in three cases, the spleen and middle cerebral artery in one case, the spleen, the middle cerebral artery and kidneys in one case.

II. *The Rise and Progress of Endocarditis as Evidenced by Clinical Observation.*—The fact which stands out pre-eminently in this connection is the association with rheumatism, acute and sub-acute. This association has been noticed ever since adequate means have existed for the detection of morbid changes in the valves of the heart; to Bouillau must be ascribed the merit of calling attention to it. It is now a matter of common experience with each of us who have to treat cases of rheumatic fever. We know that in any case of this disease there is a strong probability of endocarditis becoming manifest by a change in the valves of the heart. Discrepancies exist as to the proportion in which valvular complications are declared in acute rheumatism, but those are probably susceptible of some explanation. Amongst English observers (Fuller, Sibson, Budd, Latham, &c.), the figures approximate tolerably closely, and indicate that, in acute rheumatism endocarditis becomes manifest in one out of every two or three cases. (a) Continental observers have recorded a less proclivity, the figures of Bamberger, Lebert, Wunderlich, and Roth showing a proportion of one in five to eight cases. (b) The statistics collected for me by Dr. Gabbett from the records of the London Hospital show that in 1880, 113 cases of valvular complications were noted in 244 cases of rheumatic fever—a proportion of 46.3 per cent., and in 1881 170 in 295, or 60.6 per cent. The increasing proclivity to valvular com-

phlogions with repeated attacks of rheumatic fever is well shown by the table for 1880.

Thus, in cases of a first attack of rheumatic fever valvular changes were evidenced in 44 per cent. In cases admitted for a second attack of rheumatic fever the proportion was 48·5 per cent.

In those who had suffered from two or more previous attacks the proportion was 59·0 per cent. Or to modify the plan of operation the heart was noted as healthy in cases of a first attack of rheumatic fever in 50 per cent., in cases of a second attack 40 per cent., and after two or more attacks in 20 per cent. These statistics are somewhat modified by the experience of 1881, when the valvular morbidity was in the first attack slightly reduced (viz., 41·8 per cent.), whilst in the second attack it had greatly risen (viz., 70·8 per cent.), and after two or more attacks stood at about the same ratio (67·1 per cent.). The record of "healthy heart" was in the ratio of 37·1, 19, and 22·8 per cent. in the three classes respectively.

We may now inquire by what signs the advent of endocarditis in the course of acute rheumatism is declared? I exclude those cases which are complicated by pericarditis because those are out of the scope of my subject. First, as regards symptoms; these according to the experience of many, with which my own observations are entirely in accord, are by no means characteristic. Oftentimes there is absolutely no subjective sign which might give rise to the suspicion that the lining membrane of the heart is becoming involved in a serious disease. The course of the rheumatic fever appears to be modified in no appreciable degree. I am aware that some observers have laid greater stress on the prevalence of such subjective signs. The late Dr. Sibson, for instance, states that in nearly every one of his cases developing heart complications in acute rheumatism, the inflammation "pronounced itself by the immediate language of the heart itself, by pain in its region, by the anxious expression of the face, and its dusky or glazed hue, and by the disturbed breathing." (a) To this point I shall return hereafter.

Next as to the physical signs by which the endocardial implication is indicated or rendered probable. I believe the most frequent sign to be a prolongation of the first sound of the heart. Sir William Gull and Dr. Sutton have noted this sign. They say: "such a prolonged first sound not unfrequently in the course of a few days becomes a well-marked mitral bruit . . . it also occasionally happens that this first sound is prolonged at the apex and continues so until the patient is almost, if not actually, convalescent, and then this prolonged sound becomes a decided mitral murmur." (b) Dr. Sibson made a similar observation, prolongation of the first sound as stated by him in 18 out of 22 cases of threatened rheumatic endocarditis. (c) My own view as to the significance of this sign is, that it is due to an impairment of the valvular element of the first sound. The curtains of the valve being swollen the flap of their closure is rendered less manifest, the ear consequently perceives for the most part the muscular element of the systolic sound. The period of the disease at which the manifestation of the involvement of the endocardium occurs, is an important, though a debatable question. Hayden placed it from the sixth to the ninth day of the attack of acute rheumatism. (d) Fuller from the sixth to the twentieth day. Gull and Sutton say, however, "experience teaches that the heart becomes diseased at the very outset of the rheumatic fever, before the patients enter the hospital;" (e) and Sibson was in accord with this observation. "The prolongation of the first sound when present was generally audible on the first day." I consider that though the prolongation or murmurish character of the first sound may be heard at variable periods of the evolution of rheumatic fever it is very common to find it, as the observers last quoted have said, at the very earliest periods of evolution of the disease. I shall again ask attention to the importance of this observation. But even though a distinct mitral murmur be noted this must not be taken as decisive evidence of disease of the valves, for it may be due to regurgitation from passive yielding of the ventricular

muscle. This we shall consider in the lecture on Mitral Regurgitation.

A prolongation of the first sound or the production of a veritable systolic murmur does not, however, constitute the only sign of involvement of the endocardium in disease. To one sign I wish to call particular attention, chiefly because I want more evidence on this point. I have observed as an early sign re-duplication of the first or of the second sound of the heart; and, so far as my experience has gone, where I have observed this sign the resulting change upon this valve has induced not mitral regurgitation but mitral stenosis. I have formerly, before this Society, developed my views as to the manner by which such reduplication is effected. (a) And, again, the change may be noted exceptionally in the aorta and not in the mitral valve. I have now under my care a case in which, during the evolution of rheumatic fever, a musical diastolic murmur became manifest at the base of the heart. My view is that such murmur is caused by the vibration of a pedunculated vegetation depending from an aortic cusps.

The next inquiry I would make is whether there is any causal relation between the pyrexia of rheumatic fever and the occurrence of endocarditis? Wunderlich says: "Cardiac complications are by no means excluded by the absence of fever." (b) My own experience is entirely in accord with this statement. Again, cases of rheumatic fever which manifest hyperpyretic temperatures are not accompanied by an abnormal proportion of valvular implications. In fact, the Report of the Investigation Committee of the Clinical Society on Hyperpyrexia in Acute Rheumatism states that endocarditis was a little less frequent in the cases than in rheumatic fever generally. (c) The conclusion, therefore, is irresistible that there is no relation of causation between pyrexia and endocarditis.

Some authors have considered that there is a relation between the severity of an attack of rheumatism, the extent of the polyarthritis, and the development of valvular disease. I can only say that such is not my experience. This will engage our attention immediately.

Let us now inquire concerning those cases of endocarditis which are not associated with a history of acute or sub-acute rheumatism. These may conveniently, for purposes of investigation, be divided into two classes—(1) those which are observed in early life, (2) those which develop after maturity. In the latter class are those cases of gradual onset which involve the aortic orifice and sometimes the mitral, which are traceable to sub-inflammatory changes at the root of the aorta, and degeneration subsequently. In these cases the endocarditis and valvulitis are consecutive—they have no necessary connection with rheumatism, and their consideration may be conveniently deferred.

The study of endocarditis as it occurs in the early periods of life is, however, at the point at which our investigation has hitherto been advanced a matter of very great importance. Every practitioner is familiar with the fact that cases of disease of the valves present themselves which have shown evidence of such disease for many years, from very early periods of the life of the patient; and yet inquiry fails to elicit that the subject of such disease has ever suffered from rheumatism in any form. It is surely a matter of importance, therefore, that we should endeavour to learn how such disease originates in the period of childhood.

I have elsewhere discussed this question at some length (d) and I shall here only call your attention to a summary of such points as I think are absolutely necessary to bear in mind, when we are considering endocarditis with a view to treatment. I may, however, cite some evidence supplementary to my former lectures derived from a summary of more recent cases prepared for me by Mr. J. A. West our house-surgeon, and formerly our registrar at the North-Eastern Hospital for Children. In acute and subacute rheumatism in the child it has been considered by West, Rillet, and Barthez, and others, that the proneness to endocarditis is greater than in the adult. Rosenstein (e) has combated this view; he considers

"the disposition to endocardial affections on the whole smaller in children than after puberty." My experience entirely coincides with that of Dr. West, and is against Rosenstein, whose only recorded argument is that "he has repeatedly seen cases of rheumatism even in children, which were not followed by endocarditis. Typical rheumatic fever is much less common in the child than in the adult, the articular manifestations are slighter, but I consider the morbidity of the endocardium to be greater. Of thirty-two cases of acute and subacute rheumatism occurring in children under twelve years of age admitted into the North-Eastern Hospital during the past three years, twenty, or 62 per cent. presented signs of endocardial affection. The development of endocarditis, however, in the child has not so close a relation with the other phenomena of rheumatic fever as in the adult. It may precede, or may succeed, even after long periods, the attack. We meet with cases of endocarditis in children by no means infrequently where the manifestations of rheumatism are very slight. There may be no history such as one could interpret as of subacute rheumatism, but only very slight pains often designated "growing pain." Such has been noted by me in the following proportions in the three classes of cases: *a.* acute rheumatism, 47 cases; *b.* subacute rheumatism, 21 cases; *c.* rheumatoid pain, 8 cases.

Again the manifestation, or rather indication, of rheumatism may be even slighter still. I have noted endocarditis in cases where eruptions have been the only signs (if so they be admitted) of the rheumatic diathesis. Such eruptions are *eczema*, *erythema* (*e. circinatus* or *e. marginatum* and *purpura*. (*a*)

But there are other diseases besides rheumatism in the child with which endocarditis stands in close relation. These are chiefly scarlatina and measles. In relation with scarlatina endocarditis may occur either with or without the intervention of articular symptoms. Post-scarlatinal rheumatism is well known and bears a close similarity to ordinary rheumatic fever; associated endocarditis is, therefore, rendered probable. But I have shown from recorded cases that such endocarditis may become manifest after scarlatina, not only without the intervention of articular phenomena, but long after the period of fever has passed, and during a time when there is no elevation of the temperature of the body, no pyrexia whatever. (*b*)

Again there is evident proof that endocarditis can arise in close relation with measles. I have recorded a case in which both pericarditis and endocarditis occurred a fortnight after the commencement of convalescence from measles. At this time a perilous attack of chorea developed. There was here no obvious manifestation of rheumatism, nor hereditary tendency thereto. It appears to me that the influence of measles in predisposing to endocarditis has been much underrated. And *à fortiori*, the frequent sequence of these diseases as observed in children becomes an agency, and that, as I think very probable not only to the endocardial disease, but to acute rheumatism itself. To take examples:—

1. Scarlet fever, measles and subacute rheumatism in one year, mitral regurgitation.

2. Scarlet fever at age of two; second attack at eight, followed by measles and rheumatoid pains. Mitral regurgitation.

3. Measles at age of two, scarlet fever at three. Mitral regurgitation and aorta obstruction.

In nine other cases in which measles was noted in the previous history of cases manifesting endocardial murmurs, acute and sub-acute rheumatism were manifested in four.

After measles, just as after scarlatina, endocarditis, or pericarditis, or both combined, may develop with no signs of pyrexia.

Excluding all these probable causes, however, there yet remains a very considerable minority of cases of endocarditis in children in whom no traceable disease has led up to the valve deterioration. The condition is only betrayed by various morbid conditions, the results or concomitants of the valvular disease. I have noted twenty-seven of such cases. They have been marked by (*a*) disorders of the nervous system—hemiplegia, hemianæsthesia, epilepsy, chorea; (*b*) disorders of nutrition—wasting, anæmia, &c.; (*c*) disorders of respiration—circulation, cough, dyspnoea, or the usual phenomena of progressive cardiac failure.

Sufficient is this evidence to prove, I think, that in the child endocarditis can arise and progress without special symptoms, without pyrexia, without the disturbing influence of any acute disease. It may be asked, however, whether the form of endocarditis in such cases differs in any way from that which we know as the rheumatic form. The answer is given by the post-mortem evidence. There is no obvious difference from the essential features of rheumatic endocarditis, such as we find in the undoubtedly rheumatic subject.

(To be continued.)

RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S. Eng., M.S. Lond.,
Surgeon to the London Hospital.

PART II.—Reported Cases of Recovery—Treatment—Conclusion.

(Continued from page 29.)

EXACTLY the same defect helps to vitiate Dr. McDougall's second case. J. B., a temperate waggon driver, æt. 23, was knocked down by one of his horses and run over. One wheel ran over the lower part of his abdomen, the other over his right arm, causing a comminuted fracture of the humerus. "He was taken to a bone-setter, who reduced and treated the fracture, then placed in a cart, and driven a somewhat long distance to his home. Just before reaching it, and after an interval of fully three hours from the receipt of his accident, he was seized with pain in the belly. With this came urgent and intense desire to make water, but all attempts to do so failed. Many miles removed from medical assistance, and feeling sick and weary, he retired to rest, and *strangely enough he slept fairly well during the night.* With morning, however, came an aggravation of all his symptoms, and he sought the advice of Dr. Robertson, of Penrith. He, learning from him the total inability to pass urine, used a catheter, but only succeeded in removing four ounces. This was quite twenty hours after the last time he made water, and what he withdrew was deeply tinged with blood. The serious nature of the case was but too apparent, and he recommended his admission to the Infirmary. Bland entered the ward while I was making the morning visit, and so freely and apparently easily did he walk that I never suspected that his condition was so serious. What of his history I have now told he then related, and he was immediately sent to bed." In this preamble it will be noted that there is a striking absence of all the primary conditions but one which are associated with a rupture of the bladder into the peritoneal cavity. There had been a severe contusion in the hypogastric region, but nothing whatever is said concerning the state of the bladder. Although sober, the man did not experience, as he should have done, a feeling of something having given way within the abdomen, nor was there any pain for three hours after the injury. There was no shock or collapse, no inability to walk or stand upright, and the man passed a good night, apparently free from pain and restlessness. The next day he walked with freedom and ease, and exhibited little indication of so grave a lesion. The symptoms which pointed in the direction of injury to the bladder were the inability of the patient to micturate, and the removal of only four ounces of bloody urine after the lapse of twenty hours. The further points which, combined with the history, left little doubt in Dr. McDougall's mind that the bladder had been ruptured, were these: "The patient had a pinched, anxious expression of countenance, and marked nervous twitching of the muscles of the face. Examination of the abdomen showed percussion dullness absolute in the right iliac region, the hypogastric region, part of the umbilical region, and in a less marked degree in the left iliac region. The lightest touch gave him pain; pressure he could not bear. A full-sized catheter

(a) Vide Lectures on Diseases of the Heart in Childhood. *Medical Times and Gazette*, Dec. 27, 1879, p. 711.

(b) Lectures in *Medical Times and Gazette*, loc. cit., Oct. 26, 1879, p. 472.

with a short curve was carefully introduced, and about one ounce of bloody urine withdrawn." Here again the main prop to the diagnosis is the removal of only one ounce of bloody urine. Demonstration of the rupture succeeds. "That the matter might be rendered if possible more certain, the patient was put under chloroform, and passing my left hand into the rectum well beyond the prostate, with a short-beaked catheter in the bladder, the empty and contracted condition of the viscus was readily demonstrated. In order to remove the urine effused into the peritoneal cavity, a No. 2 aspirator needle was introduced in the centre line an inch above the pubes. Bloody urine escaped slowly through it, and when nearly five ounces had been withdrawn, the instrument, partly due to the consistence of the fluid, partly to some fault in the suction apparatus, struck work. A few hours later the largest sized trocar of the aspirator was introduced obliquely downwards and backwards close above the pubes; the aspirator fixed, and twenty-one ounces of fluid (urine?) were withdrawn. As it flowed the man expressed relief, and ere the operation was finished, his pulse, which had previously been depressed and irregular, became sharper and more steady. All abdominal dulness had now disappeared, and the acute tenderness was even less." Prior to the tapping, the patient showed "very evident signs of abdominal inflammation" and some "symptoms suspiciously indicative of uræmia." Vomiting, which had occurred for the first time shortly after the first use of the aspirator, had rendered the pain more severe and the vital depression greater. A catheter was retained, and the urine, still containing much blood, passed freely from it, except on the evening of the second day, when Mr. Spence, the house surgeon, "fearing that the urine was again finding its way into the peritoneum, used the aspirator, and withdrew several ounces of sanguineous fluid. The removal of this, which examination proved to be largely sero-purulent, was followed by benefit, for in a short time the urine again passed guttatim by the catheter." The main constitutional symptoms were jaundice and delirium, the jaundice appearing on the third day, and the delirium on the fourth. The abdomen was tympanitic. At the end of the seventh day the patient passed nearly a pint of clear urine during an effort of defecation. The case lasted altogether for a month, a fluctuating temperature, nocturnal delirium, a tympanitic condition of the abdomen, perceptible dulness on percussion, in the hypogastric region, and diarrhoea being the main symptoms recorded.

In this case all the abdominal symptoms, with the exception of the vesical, are readily accounted for by the injury sustained from the passage of a cart wheel over the belly, and the diagnosis of rupture of the bladder into the peritoneal cavity rests upon the inability to micturate, the presence of blood in the urine, the small amount of urine drawn off with the catheter, and upon the results of manual examination and the use of the aspirator. Are these circumstances conclusive? I think not by any means. An intra-peritoneal rupture is negatived by the whole history of the symptoms immediately following the accident, and the subsequent examination of the case. Accordingly, Dr. Max Bartels carefully excludes the case from the category of intra peritoneal ruptures, but seems willing to admit that it may have been an extra-peritoneal rupture, a view which is adopted also by Dr. Vincent. If so, the urine must have been freely extravasated into the connective tissue in front of the bladder, and it must be concluded that the aspirator sufficed to remove all of it, and to prevent the inflammation and suppuration which ordinarily supervene when urine has been effused. This difficulty appears to me to be greater than the difficulty of supposing that Dr. McDougall might possibly have been mistaken in his conclusion that the bladder was empty. Mr. Walsham (a) says that with

the whole hand in the rectum, "the bladder is easily recognised when moderately distended, as a soft, fluctuating tumour behind the prostate; when empty, it cannot be distinguished from the intestines, which then descend between the rectum and the pubes." Dr. McDougall says that he introduced his left hand into the rectum well beyond the prostate, with a short-beaked catheter in the bladder, and readily demonstrated the empty contracted condition of the viscus, but, in commenting on the case, he observes: "Even with great part of my hand in the rectum, it was with difficulty that I could reach the upper border of the contracted bladder, and I certainly quite failed to detect such evident fluctuation as would have warranted the plunging in of a trocar." This dubious account renders it probable that there was some unusual condition of parts produced by the accident, and I would suggest that the bladder sustained a contusion during the passage of the cart wheel; that possibly the pubo-vesical ligaments were ruptured, and the bladder pushed backwards, blood being extravasated between the viscus and the pubes; and that the amount of secretion was much diminished by the injury. The inability to micturate, the blood in the urine, and the fact that a short beaked catheter failed to remove the main bulk of the urine secreted after the accident, would be explained, and the conclusion would follow that the aspirator pushed deeply downwards and backwards above the os pubis, entered the organ and drew off the retained urine. It is particularly noteworthy that some hours elapsed between the first and second employment of the aspirator, time sufficient for the secretion of twenty-one ounces, and on the second occasion there is no record of an attempt at catheterism. Whether the fluid withdrawn was urine or not is not stated.

Dr. Erskine Mason's (a) case was this: M. B., 26, fell downstairs on Dec. 25th, 1871, and sustained some bruises about the face, arms, and legs. What part of the body he struck in his fall he was unable to state. The next day (Dec. 26) he was admitted into Roosevelt Hospital. He had urgent desire but inability to pass water. A No. 10 catheter, passed easily, drew off a few drops of urine streaked with blood. He complained of pains about the hips, and some tenderness over the hypogastrium. On Dec. 27th the catheter was again passed, and four ounces of urine, "with some blood," drawn off. Tenderness over the abdomen seemed to be increasing. In the afternoon an injection of ol. ric. ʒj. caused no movement of the bowels. About four o'clock he walked to the water closet, and voided a small quantity of urine. The expression of his countenance was anxious and very pale; his tongue was very much furred; he was very thirsty; his pulse was only 68 small, and his temperature was 98½. A catheter was introduced, and clear urine was drawn off. The finger in the rectum could not detect any injury to the urethra, but felt *doubtfully* a swelling posterior to and a little to the left of the prostate. The patient complained of great pain in the lumbar region. Dr. Mason could not decide whether the kidneys were injured or the bladder ruptured. Early on Dec. 28th patient was restless and thirsty, with pulse at 112, and temp. 102°. A small quantity of bloody urine was drawn off. The abdomen was hard and extremely painful. At 6.30 p.m. and 9 a.m. a little bloody urine was drawn, but some difficulty was experienced in passing the catheter. At 10 a.m., when seen by Dr. Mason, the patient was lying in bed with his knees drawn up, with great tympanitis, hicough and vomiting, excessive tenderness over the whole abdomen, small wiry pulse of 120, coated tongue, great restlessness, and cool extremities. The diagnosis now formed was rupture of the bladder and general peritonitis. Lateral lithotomy was performed. Digital examination of the rectum detected posteriorly to the prostate a decided tumour yielding a sense of fluctua-

(a) Holden's Landmarks, p. 70.

(a) New York Medical Journal, 1872.

tion. There was no laceration of the urethra or neck of the bladder around the prostate; no thickening or induration of the tissues anterior to the neck of the bladder. A large-sized staff was passed into the bladder with the greatest facility, and the bladder was laid open. *Bloody urine escaped in quantity.* Passing his finger into the bladder so as to enlarge the opening, Dr. Mason felt confident that he detected a rent in the posterior wall of the viscus, but he did not examine this opening thoroughly, as he feared he might do injury if he pursued his investigations farther in that direction. Two facts were observed—one that the interior of the bladder was sensibly cooler than the surface; the other the disappearance of the tumour felt through the rectum. The diagnosis now made was that the rupture had taken place through the posterior wall of the bladder, that the rent had extended through the peritoneal covering, and that the urine had extravasated into the pelvic cavity, but rested chiefly in the posterior *cul de sac*. Owing to venous hæmorrhage the wound was tamponed with lint for two days. On the second day it was noted, "a brown discolouration is now observed over the inguinal hypogastric and peritoneal regions and down the thighs." On the third day the parts presented a hard and indurated feeling, and the patient was bathed in profuse perspiration, having a urinous odour. On the fourth day the discolouration was fading, and there was considerable perspiration of the same strong urinous odour. The patient made a complete recovery, and was discharged cured on the thirty-seventh day after the operation.

Dr. Mason's diagnosis of intra-peritoneal rupture of the bladder has been challenged by Mr. Willett on the following grounds:—1. The absence of any evidence of direct injury to the supra-pubic region, and of distension of the viscus at the time of the injury. 2. The fact that the symptoms did not warrant a diagnosis for seventy hours when peritonitis supervened, whereas blood and urine effused into the peritoneal cavity would have excited that action at a much earlier period. 3. If Dr. Mason had felt quite sure that bloody urine had collected in the peritoneal cavity, he would not have been so fearful of exploring the rent he thought he detected in the bladder, but would have deemed it essential to make certain that he had established a vent for the effusion. 4. The improbability that in an intra-peritoneal rupture urine would find its way only into the pelvic *cul de sac*, and not invade the general cavity of the peritoneum. Mr. Willett adds, "That a laceration occurred immediately posterior to the prostate is, I think, almost certain, as also that when the effused urine encroached upon the peritoneum, local peritonitis was excited. Equally I regard it as quite clear that the patient owed his life to Dr. Mason's decisive operation, and the timely performance of it." With Mr. Willett's opinion that Dr. Mason's case was not one of rupture of the bladder into the peritoneal cavity I entirely concur; but, curiously enough, Mr. Willett does not see that the absence of evidence of a distended bladder, and of direct injury to the hypogastric region, as well as the other details, militates equally against a simple extra-peritoneal rupture immediately behind the prostate. A simple traumatic rupture in this situation is a form of lesion almost, if not quite, unparalleled and inexplicable, as occurring from a fall downstairs to an almost empty bladder. Moreover, if urine had issued from a rent in this situation, in seventy hours it would either have become widely diffused, or confined in an adventitious cyst behind the prostate. In the one case lateral cystotomy would have effected little, and in the other, unless extended deeply through the prostate and into the cyst, would have left the collection of urine untouched. Fortunately, the records of the case render it as clear as noonday that neither the one nor the other condition existed. Digital examination had established the fact that no urine was effused between the rectum and prostate, or anteriorly to the latter

organ, and that the fluctuating tumour was well behind the gland. The lateral cystotomy was performed *secundum artem*. The incision in the prostate was limited, and the finger was used to dilate the aperture, and yet the moment the knife had entered the bladder, with the apex of the prostate only notched, and even before the passage of the finger, bloody urine escaped in quantity, and the tumour disappeared. No demonstration could more convincingly have proved that the fluctuating tumour felt with the finger was the bladder itself. To the small quantity of urine drawn off by the house-surgeon, and subsequently by Dr. Mason, very little importance can be attached, for difficulty was experienced by the house-surgeon in passing the catheter, and the possibilities of false passages are infinite. As for the brown discolouration, on which Mr. Willett lays some stress, it is significant of bruising of subcutaneous tissues and blood extravasation, and the urinous odour, commonly noticeable after a lateral cystotomy, has a pervading influence readily transferable to the skin in the mind of the observer. Thus, by the process of exclusion supported by the clinical record of the case we may conclude that, if Dr. Mason felt a laceration on the posterior wall of the bladder, it was confined to the mucous, submucous, and muscular strata. A rent of this kind might readily be followed by peritoneal irritation through the close proximity of the urine to the vesical surface of the peritoneum, and Dr. Mason exercised a wise discretion when he left it unexplored.

(To be continued.)

THE ELECTRICAL TREATMENT OF ENLARGED GLANDS. (a)

By HERCULES H. MACDONNELL, M.D., M.Ch.,
B.A. Univ. Dub.

Surgeon to County Louth Infirmary and Surgeon to Her Majesty's Prison, &c.

GENTLEMEN,—I am desirous of bringing under your notice the treatment of an affection only too well known to all present, and which occasions considerable anxiety to the general practitioner when met with, not only on account of the great difficulty sometimes felt in removing it, but also the unpleasant cicatrices and other complications which result. I refer to enlarged glands, whether having an element of struma as a factor in their production or being essentially adenoid cell proliferation. The development of a gland consisting, as you are aware, of a local hyperplasia, or development of diverticula from the acinar tubules of the gland and secondary proliferation of the enclosed epithelium, any subsequent degeneration of this epithelium gives rise to caseous masses in the growth. There is frequently a fibroid capsule enveloping the entire structure, and I cannot help thinking that the rapidity of growth and infection of neighbouring glands is modified and retarded by its thickness and vitality.

There are three well-defined stages in this affection, the third of which is that of disintegration, suppuration, and its concomitant evils. My object to-day is to bring before your notice the details of a treatment which is most successful in anticipating this degeneration and guiding to a satisfactory termination this most unpleasant affection.

You are doubtless familiar with a treatment adopted by Mr. Golding Bird and termed the electrolytic caustic method. In this his object is to remove the gland by permeating it with chloride of zinc. This he effects by passing a zinc electrode into the substance of the gland, the silver electrode inlaid on the previously blistered surface. A battery with its circuit completed by a copper wire attached to both is thus formed, the exciting fluid for which is the serum of the blood, the chlorides of which are taken up and replaced by the chloride of zinc.

(a) Read before the Meath and Louth Medical Society, Dec. 22, 1882.

This treatment is most effectual, but can only be applied when caseous or other degeneration has actually occurred; therefore any well-conceived line of treatment which anticipates that stage must be welcome to all. I shall, therefore, briefly introduce to your notice the following suggestions, and gives notes of four or five cases out of many in which I have found them thoroughly satisfactory.

Having selected the gland or mass of glands you purpose treating, have the surface well cleaned and wiped over with a solution of salt. Apply the negative pole of a Leclanché battery, having two cells connected, over the most prominent part, and the positive about three inches apart; keep moving the positive reophore in a circle round the negative quite slowly, till the electrical stimulus has been sufficiently applied. Usually five to six minutes is long enough. On the first occasion two cells are enough, as it accustoms the tissues to the action. On the succeeding applications the effect of additional cells may be tried; but should there be the slightest appearance of inflammatory action, as evidenced by a bluish-white tint under the negative reophore, a couple of cells must be at once disconnected, or the application discontinued on that occasion. I have never used more than eighteen cells continued for three minutes, and have found that from eight to twelve cells give the most satisfactory and rapid results. The length of each application varies for different individuals. In some patients three or four minutes twice daily seemed to suffice; in others a longer application only once answered better. Even different glands, or masses of glands in the same individual, progressed more rapidly under varying conditions of length, strength, and frequency of application.

CASE 1.—Mr. Q. D., *æt.* 19, suffering from an enlarged sub-maxillary gland the size of a large walnut. Has resisted treatment by iodine, blistering, cod-liver oil, iron and phosphorus, &c. In Oct. 1879 began by applying once daily four cells of a Leclanché battery, gradually increasing at intervals of two days to ten cells. After the second application the gland began to diminish in size. The battery was applied twenty-five times in all, when the enlargement had totally disappeared.

CASE 2.—Mary G., *æt.* 20, had a mass of enlarged glands at angle of jaw on either side, extending up behind the ears. On Jan. 3, 1880, electricity was applied four times a week, gradually increasing the strength from two to ten cells. At the fifth application the glandular mass on the right side began to decrease, and at the seventh, that on the left. There were thirty applications in all, when only a faint enlargement could be detected on the right side. This subsequently disappeared.

CASE 3.—Catherine B., *æt.* 23, admitted to Co. Louth Infirmary on March 2, 1880. There was an enormous mass of enlarged glands on left side of neck, also a solitary one the size of half an orange on the right side. These had lasted for a year, and resisted treatment by iodine, blistering, and cod-liver oil. Four cells were applied twice daily for three days, each time for five minutes. At the sixth application diminution was perceptible, and at the end of three weeks the masses had almost disappeared. She returned home on April 1, and on the 21st there was no trace whatever of the glands.

CASE 4.—Mary McH., *æt.* 22, was admitted to Co. Louth Infirmary on April 29, 1881. The left sub-maxillary gland was enlarged to the size of a hen's egg. She had been previously treated with external applications of iodine, blistering, &c. Eight cells of a Leclanché battery were ordered to be applied three times daily for four minutes, five days subsequently increased to twelve cells. On May 8, 9, and 10, sixteen cells were applied; on the 11th, 12th, and 13th, only twelve cells; on the 14th she had two applications of twelve cells and one of eighteen cells; on the 15th and 16th, two applications of twelve cells. The tumour all this time was steadily decreasing, and she left on the 31st.

The foregoing cases are fair examples of what a steady application of the continuous current will effect in these

troublesome cases. It has struck me that fair-skinned patients bear a more heroic line of treatment better than dark ones, and re-act more quickly to the electrical stimulus. In conclusion, gentlemen, I have no doubt whatever that, if applied in the manner indicated, electricity cannot fail to give in your hands that complete satisfaction which I have experienced.

AN ESSAY UPON HIP-JOINT DISEASE.

By S. D. CLIPPINGDALE, M.D., F.R.C.S.

(Continued from page 31.)

IV.—THE MORBID ANATOMY.

THE changes in the structures of the joint produced by the disease are as follows:—

1. *The synovial membrane* may be simply congested, inflamed, torn into shreds, or entirely removed. In some cases the inflammatory process assumes the plastic form and lymph is thrown out into the cavity of the joint and bands formed across it. In other cases the inflammation becomes suppurative in its character, and pus is produced. It is probable that the synovial membrane is destroyed only in that kind of inflammation which becomes suppurative. An exception to this rule, however, is to be seen in a specimen in the museum of the Children's Hospital, (a) Ormond Street, in which ulceration is shown to have extended to the articular cartilages without the formation of pus.

2. *The articular cartilage* soon succumbs after the destruction of its investing and protecting synovial membrane. If the disease begins as a synovitis, the cartilage is gradually destroyed from its free surface, and its ulcers are concavities, with bevelled margins. If, however, the disease begins as an osteitis, pus may accumulate beneath the articular cartilage, and, being unable to pierce it, spreads under it until it escapes at a weak point. This is why we find the cartilage in some cases detached in plates. An ulcer in the cartilage is never properly repaired, but may become cicatrised by fibrous tissue, as is shown in one of Sir B. Brodie's cases. (b) The period when ulceration takes place is uncertain, and depends upon many circumstances, but I would suggest that it does so in most cases before the end of the second month.

3. *The head and neck of the femur*.—In a few cases the disease commences in bone, but in the majority this tissue is involved only in the advanced stage, and subsequently to destruction of the investing cartilage. The head and neck of the femur may become altered in size, shape, position (dislocation), and in structure.

(a) *Alteration in Size*.—The head of the femur never enlarges. Whatever growth of bone takes place during ankylosis is found around the trochanter or neck, and not upon the head. The head is generally reduced in size to a greater or less extent, and in some cases altogether destroyed. The whole of the head having been removed, the ulcerative process may extend to the neck, and, reaching the trochanters, may excavate them, leaving them mere shells of bone, or may consume them. The trochanters having gone, the disease may attack the shaft of the bone, but rarely extends along it to any considerable extent. In young subjects the head of the femur may become detached at its epiphyseal junction, and, lying loose in the pus, may become partly absorbed. In one case it became reduced to a nodule of bone the size of a pea. (c)

(b) *Alteration in Shape*.—The head of the femur, as a rule, becomes more or less flattened. Flattening takes place from above downwards, and is the result of the upward pressure of the softened bone against the rim of the acetabulum. In some cases a groove is produced upon the head of the femur by the rim of acetabulum when pressure has existed for a long time. By long

(c) St. Bartholomew's Hospital Museum, Prep. No. 624.

moulding in the acetabulum, the head of the femur may become expanded at its margin, umbel-like. When the entire head has been removed, a new one may be moulded from the neck. This process proceeds sometimes to the formation of a distinct neck, to which a fresh capsular ligament is attached, and a fresh articular surface, with distinct layer of cartilage. (See drawing below.)

This process is sometimes described erroneously in museum catalogues and elsewhere as "shortening of the neck."

(c) *Alteration in Position.*—Dislocation of the head of the femur may take place in any direction, and may be partial or complete. Partial dislocation occurs when the acetabulum is much enlarged by disease, so that the head of the femur, although thrown out of its normal position, is still in contact with some part of its socket. In every case of dislocation, complete or partial, three structural changes take place, to a greater or less extent—viz., loss of substance in the acetabulum, loss of substance in the head of the femur, and destruction or expansion of the capsular ligament.

The period at which dislocation takes place varies. In a case of Coulson's it occurred as soon as two months after the onset of the disease. It probably seldom takes place so soon. From the examination of a large number of cases and specimens, I am induced to think that it rarely takes place before the third or after the eighteenth month.

The causes of dislocation are both active and passive. The former being contraction of the muscles; the latter being alteration in joint structures described above. Mr. Hilton considers dislocation to occur generally at night, just after the patient has fallen asleep, when sensation is in abeyance, and contraction of the muscles by reflex nervous influence takes place unchecked.

Varieties of Dislocation.—Dislocation may take place in five directions, namely—(1) upwards and backwards; (2) upwards and forwards; (3) downwards and backwards; (4) downwards and forwards; (5) directly inwards through a perforation in the acetabulum. The relative frequency of these five varieties is shown in the following table of sixty-three cases:—

Upwards and backwards	in 49 cases, or 77·7 per cent.
Upwards and forwards	" 4 " 6·3 "
Downwards and backwards	" 4 " 6·3 "
Downwards and forwards	" 4 " 6·3 "
Through acetabulum	" 2 " 3·1 "

The above table merely illustrates what is well known—the frequency of dislocation in an upward and backward direction. The displacement corresponds to that which takes place when the bone is dislocated as a result of violence. Its frequency is due, probably, to the manner in which the patient lies in bed—namely, with his thigh flexed and adducted. In this position the head of the femur is kept in constant contact with the upper and back part of the acetabulum, and requires but little pressure to force it over its rim. Cases of dislocation, upwards and forwards, are mentioned by Mr. Timothy Holmes, Mr. Barwell, and others.

A case of dislocation downwards and backwards until the sciatic notch was reached, occurred in the practice of Sir James Earle; and an interesting case of the same nature is described by Coulson. In this case the patient was a lad, *æt.* 14, who had a habit of placing the affected leg over the sound one; and Mr. Coulson supposes that on one occasion in restoring his limb to its place, this form of dislocation was produced. In the St. Bartholomew's Hospital Museum is a specimen (*a*) showing dislocation into the sciatic notch, with the sciatic nerve pressed upon, so that sciatica must have been produced. There is no history of the case.

Dislocation downwards and forwards into the foramen ovale occurred in the practices of Sir C. Blicke, Mr. Hicks, of Emsworth, Baron Boyer, and Sir B. Brodie. All four cases are given in Coulson's work. A specimen from Sir C. Blicke's case is said to be in the museum of the Royal College of Surgeons, but I have been unable to find it.

Dislocation into the cavity of the pelvis through a hole in the floor of the acetabulum only occurs when the head of the femur remains in a largely diseased acetabulum—3 rare occurrence. In no case is the dislocation perfect; usually there is nothing more than a bulging of the extremity of the head through the orifice. Three specimens of this condition exist in the London museums, (*b*) and these have the following points in common: 1. The patient was a child. 2. The disease had lasted about two years. 3. The head of the femur, much reduced in size, had become conical in shape.

Natural Prevention of Dislocation.—Prevention of dislocation may occur naturally in two ways: 1. By what has just been referred to—passage of the head of the femur through a perforation; and 2. By the small trochanter catching in the perforation. (*c*)

(d) *Alteration of Head of Femur in Structure and Consistence.*—The natural bony tissue of the head may become softened by inflammation, or hardened by porcellanous deposit. It may contain deposits of miliary tubercle, caseous matter, or pus. It may have cavities, and these may be void of contents, or hold sequestra of bone. Deposit of porcellanous material is a rare occurrence. It resembles what is frequently met with in another affection of the articulation—chronic rheumatic arthritis, and is due, probably, to a continuation of friction after the removal of articular cartilage, and after cessation of all inflammatory action. In a case which occurred to Sir B. Brodie, the patient was 36 years of age.

Special.

CHOLERA AND DIRT.

CHOLERA—so we learn—and whatever other influences are unfavourable to human longevity, are being stamped out of India. But is longevity of itself so very much to be desired after all? "Reports" at our disposal give no information on this particular question. Among the measures adopted in view to ensure longevity to the present and all future generations of men and women in Britain's greatest dependency, a great and important work is in progress. Dirt is described as the most formidable enemy to be encountered by the "sanitary reformer," and accordingly against dirt our Indian officials wage an incessant war. One would think that a certain number of native scavengers, armed with brooms and shovels, might save "officials" much trouble in this respect. Great capital is made out of the circumstance that several British soldiers

(c) St. Bartholomew's Hospital, Prep. 687.

who had so far departed from the traditional habits of their class as to become water-drinkers, were seized with "enteric" fever. But in the first place the question has been asked, Were they really seized with enteric fever, or was it that the name was given to what was no more than ordinary "seasoning fever," such as young men are liable to in India? Another point that might arise on reading the account given, concerns the dangers which beset the British water-drinking soldier in India. But surely this is not the moral indicated in the Report referred to. We learn that cholera was much less severe in its ravages in almost every part of India in 1881 than in previous years. But then comes the statement that "this favourable state of things is attributed to the abundant rainfall, and to the generally low price of the necessaries of life; it is not believed that sanitary measures have had much effect upon cholera visitations. So that, after all, a favourable season, producing abundance of food, brought about also a decrease of cholera among the people; and the confession is made that really dirt, against which Indian officials wage so relentless a war, has had very little to do with the particular disease of which it is asserted that it is being stamped out by means alone of this very war against dirt. Surely, therefore, the ultimate grounds upon which the war has been declared are those upon which a late European monarch undertook one of his many campaigns—namely, an idea; only the monarch referred to was successful.

The general question, how far dirt and cholera are necessarily connected with each other, obtains replies of very different kinds from the results of observation of different epidemics. A few examples may be given:—

In 1818 the city of Seringapatam was described as being a very sink of nastiness, and in it cholera occurred with peculiar intensity. Prior to 1848 it had been remarked that certain moorings, in the river Hooghly, off Calcutta, were more obnoxious to the disease than others. The localities specially indicated were those in the vicinity of sewers, or close to the Armenian Ghât, where the bodies of dead Hindoos were burnt. It was observed, however, that none of those localities were at all times affected during the epidemic prevalence of cholera; that some of them were quite absolutely free from the disease for a year or more at a time, although sooner or later it returned to each; that the ships moored nearest to the sewers often escaped, while those in the second, or even third, tier beyond, were attacked. Neither was cholera confined to the vessels so situated, but often attacked the crews of ships moored off the Esplanade in positions considered healthy. In 1856 the ravages of the disease were very great at Meerut—that station noted as being well drained and generally healthy. On the same occasion, at Saharunpore—a peculiarly dirty city—few persons suffered from the disease. In 1861 the flooring of the barracks of the "King's Mews," at Lucknow, had been filled up with dung and litter, a coating of clay and plaster being spread over all. With the advent of the hot season, cholera of very virulent type attacked the men of the 52nd Regiment occupying those barracks, although the disease was nowhere else known to exist in that crowded and dirty city. Thus, then, it happened that, where all was dirty, cholera confined itself to one such locality to the exception of others equally dirty.

How are such occurrences to be explained upon the dirt theory alone of the causation of cholera?

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

THE special general meeting of the Royal Medical Benevolent College, convened on Wednesday last for the purpose of effecting certain alterations in the bye-laws of the institution afforded a striking contrast to that of the 20th of December, which, as we have already stated, proved a failure from a want of a sufficient number of Governors required to constitute a legal meeting. Those of the subscribers present on that occasion, and who were compelled to submit to a loss of valuable time, must have experienced surprise to find assembled punctually at the hour appointed a somewhat unusually large gathering with an air of business about it; the reason for which was soon made manifest. The Chairman stated that during the past term the Council had been anxiously and carefully engaged in considering the whole existing arrangements of the College, with the view of effecting changes which, it was hoped, would lead to an improved tone in the discipline and management of the School and College, and prevent any chance of a recurrence of disorder. An Investigation Committee had also thoroughly gone into the domestic as well as the scholastic affairs, and having brought up a well-considered report, it had been determined to ask the Governors to strengthen the hands of the head master by giving him the direct control over every department, and by entrusting to him the power to remove from the College on his own responsibility any boys (except Foundation scholars) whose presence would, in his opinion, be injurious to the welfare of the school—a system, be it remembered, quite in accord with that which prevails in almost all the best public schools of the kingdom; and therefore much importance was attached to it by the Council.

From the opening speech of the Chairman no one could have supposed that the majority of the members of Council were not agreed upon so important a question, but, to the surprise of those outside this body, this proved to be the case. On the resolution for the alteration of the bye-laws in accordance with what we have stated being moved and seconded, a member of Council rose and proposed an amendment, to shelve the question and refer it back to the Council for further consideration. This led to a long and a warm discussion, for the most part carried on by members of Council, some of whom indulged in somewhat ungenerous attacks upon the head master, who, it was said, "was wanting in administrative ability," and therefore not the man to be entrusted with the additional powers the Governors were asked to confer upon him. The upshot of this want of agreement of Council was that the amendment was carried by a small majority, and the head master's authority must, in the meantime, and if things remain as they are, be considerably weakened for good in the management of the School and College.

It is not too much to expect that, should it be thought

necessary to bring the management and discipline of the College before a meeting of Governors again, that members of Council will, at any rate, have made up their minds as to what is the right thing to be done and the right horse to be saddled, in case of any recurrence of disorder and lack of discipline.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 13TH, 1882.

The President, Professor LISTER, F.R.S., in the chair.

Dr. COXWELL read notes of a case which he exhibited at the last meeting. It was that of a child, *æt.* 13, with symptoms resembling those of myxœdema. Until eight years of age, she differed in no way from other children, and could read a chapter out of the Bible or a story as well as her mother, could write, and learnt arithmetic. A great change then came over her; she would often fall asleep, even when eating her meals; her memory became defective, and if sent to do anything she would wander about in a aimless fashion. Later, her speech became thick and indistinct; she suffered from headache; her head drooped forward on to her chest; her hands and feet became very cold; her legs became weak and her gait unsteady. She was lately a patient in the National Hospital for the Paralyse and Epileptic, under the care of Dr. Hughlings-Jackson. The appearance of her face is very suggestive of myxœdema, her skin being translucent, with a circumscribed patch of redness in the centre of the cheeks; the lower eyelids swollen; the nose broad; the eyes prominent and well formed. The thyroid glands seem diminished, and there are no abnormal fatty tumours in the region of the neck or elsewhere. While under observation, her temperature was frequently as low as 95.6. She was often extremely restless at night, and had frequent attacks of screaming. Her power of speech became worse, till at last she could hardly utter a single sound, the lips being seen to move ineffectually while she attempted to do so. She could not kiss her mother or puff out her cheeks, and her food would often remain seven or eight minutes between her teeth and lips. There was a general overclouding of the intellect. Dr. Coxwell drew attention to the fact that very pronounced mental disease has been reported in myxœdema, and that Dr. Ord had a patient suffering from that disease with marked affection of the bulb, a point of similarity with the present case of some importance. If the case was one of myxœdema, it was of interest, as being the first recorded in a child. If it was one of simple imbecility, it was remarkable on account of the bulbar symptoms and the likeness it bore to myxœdema. The arguments in favour of sporadic cretinism were few, and outbalanced by the absence of most of the characteristics of that disease.

Mr. J. N. C. DAVIS-COLLEY on

A CASE OF ENORMOUS ENLARGEMENT OF THE LOWER LIP, CURED BY OPERATION.

Richard B. D., a clerk, *æt.* 36, was admitted into Guy's Hospital in August, 1881, with a remarkable swelling of the lower lip. Fourteen years before he had a chancre on the penis, followed by soreness of the tongue and swelling of both lips, especially the lower. There was never any rash on the skin. He was a very great smoker. The lower lip was of enormous size, everted, and pendent, so that its border was on a level with the tip of the chin, while the lower teeth were in front completely exposed to view. The mucous membrane was fissured in parts, but otherwise natural. The tissues were a little firmer than usual, but not at all indurated. There was a little tenderness on pressure. From side to side it measured three inches, from above downwards one inch and a quarter, and in thickness seven-eighths of an inch. The upper lip and tongue showed signs of chronic inflammation. There was no enlargement of the adjacent glands. He left off smoking, and was at first treated with anti-syphilitic remedies. The mucous membrane became more healthy, but the lip remained the same size. Some reduction was then effected by pressure

between thin slips of wood. The lip became smaller and flaccid, but was still coated and pendent. On November 8 a V-shaped piece was removed from the centre of the swollen lip, and a rapid recovery ensued. When last seen, he had no longer any eversion of the lip, which had assumed a perfectly healthy and normal aspect. Mr. Davis-Colley brought the case forward as a striking example of the enlargement of the lip, which occasionally results from chronic inflammation. There was nothing in the patient's family history to indicate a scrofulous tendency. The evidence of secondary syphilis was doubtful, and there was no record of mercurial salivation. On the whole, Mr. Davis-Colley was disposed to attribute the disease primarily to syphilis, and secondarily, to the constant irritation of the inflamed surface by excessive smoking. The case was also interesting on account of the success which followed excision of part of the lip after the more or less complete failure of other remedial measures.

Mr. C. LUCAS, who had seen the case in question, testified to the admirable result of the operation. He did not feel disposed to attribute such cases to struma so much as to inherited or acquired syphilis, which cause might, and probably most usually did, receive help from the influence of mercury administered to antagonise it. In Mr. Colley's patient irritation produced by smoking was also an important factor in producing the enlargement, and carious teeth might not improbably have tended in the same direction. Mr. Lucas related the history of a young lady who consulted the most eminent authorities on account of extensive thickening of her lip, lasting over twelve months. The condition was attributed variously to herpes, lupus, &c., but it was entirely remedied by the extraction of the two lateral incisors, which were decayed and filled with stopping, while from one a permanent sinus extended, to which the irritation causing the enlarged lip was due.

Dr. W. B. HADDEN suggested that the thickening might be consequent on lymphatic obstruction.

Prof. LISTER commented on the interesting nature of the case, shown in the readiness with which the portion of lip remaining, after ablation of a V-shaped piece, returned to the normal. This presented analogy to the restoration of enlarged tonsils following excision of portions only of their substance, and to those cases in which similar restoration of neighbouring structures sympathetically affected took place—*e.g.*, recovery of hearing after excision of part of enlarged tonsils, consequent on a return to the usual conditions of the Eustachian tube, which not rarely shares in the changes undergone by the tonsil. An instance of the kind had recently occurred in his own practice, the patient, a youth of fifteen, and completely deaf, being able to hear well as a result of partial removal of his enlarged tonsil. In another case of lipoma of the nose—*grog-blossom*—recently operated on, he had pared down the chronically-inflamed and hypertrophied dermis of the organ, but he did not interfere with the adjacent structures, though they were involved in the changes produced by overgrowth. These, as well as the nose itself, were completely restored to a normal state.

Dr. MEADOWS instanced a case occurring in his own practice in which part of the hypertrophied *mons veneris* was removed by means of the *écoraseur* from a lady, thirty-two years of age, with the result that menstruation soon after ceased, through reflex atrophy of the ovaries.

Mr. DAVIS-COLLEY considered that the result in his own case was influenced by diminution of thickening in the lip by tension of the part after operation, and also by reduction of the pendulous condition previously existing. He had observed nothing to indicate a lymphatic origin of the abnormality, and, respecting the teeth, could only say that those which were exposed were not carious. On the whole, he attributed the affection of the lip to the action of secondary syphilitic taint, combined with irritation from tobacco-smoking.

Mr. C. GOLDING BIRD on a

CASE OF TRANSPATELLAR EXCISION OF THE KNEE.

The operation was on the person of a lad, *æt.* 13, fairly healthy himself, but with a family history of phthisis. There was a year's history of articular arthritis of the right knee with pulpy disease. Excision was eventually performed on May 9th, 1882. It differed from an ordinary excision in that the transverse incision was made across the middle of the patella which was then sawn in two, the two fragments, with the soft parts, being turned up and down. The excision was then completed as usual, the articular surfaces of the tibia and femur being removed. Some pulpy

thickening was removed from the under side of the patella, and when the limb had been straightened two carbolised sutures were passed through its substance, and so its two fragments were united. Primary union was obtained, and nothing more was seen of the patella sutures. Until September 12th he walked about with a stiff bandage on the knee and with crutches, after that date he was ordered to discard all support. He now has a movable patella, and half an inch shortening. He has all the advantages of retaining the patella; but, besides that, there is a gain by this method of operating, since the surgeon can freely examine and manipulate the joint, more freely indeed than where, with the idea of retaining the knee-cap, the lateral incisions are employed. Two great advantages remain to the patient by keeping the normal attachments of the patella. The quadriceps opposes the ham-strings and so does away with the necessity of employing a stiff bandage for years, to prevent posterior displacement of the leg; and the rectus femoris, considered as arising below, has its full play upon the trunk in preserving equilibrium, whilst it also allows of the perfectly natural forward motion of the limb in walking, and this last is not the case where the ligamentum patellæ has been sacrificed.

Mr. HOWARD MARSH observed that all surgeons felt dissatisfied with the results of excision often seen, and he had often thought it a wasteful proceeding to sacrifice the patella in these operations, thereby depriving the limb of whatever advantage might be attained by its presence as an assistant to the quadriceps extensor.

Mr. GANT said he had rarely found the patella escaped being involved in the disease, and even when this was not the case he had never witnessed any special advantage obtained from preserving it. He had very recently had the opportunity of examining a patient on whom he operated six years ago, the patella being then removed. The result was a most useful and successful limb, and he could quote similar consequences in a great number of instances. In the average cases union occurred in three months, and then a back splint and moveable apparatus was adopted for not more than three months longer; but in some cases he had found no support to be necessary after two and a-half to three months from the date of operation.

Mr. C. HEATH bore witness to the admirable result obtained in Mr. Golding Bird's case, and agreed with Mr. Gant that the patella rarely fails to be involved in disease of the knee-joint. He thought, however, that when these cases came under treatment at an early date, when the mischief had not extended to the bony structure, the patella should be retained *in situ*, with a view to afford all possible assistance towards the wished for good result.

Mr. LISTER pointed out that Volkmann had advocated transpatellar operation for years. He agreed with Mr. Gant that in old-standing cases where sinuses extend from the joints removal of the patella and the affected ends of the other bones should be performed. But when the skin had not been broken, a much less amount of the tibia and femur would require removal, and thus a more extensive surface for ankylosis be left; and the imperfect nutrition consequent on disease in these cases would under such circumstances be much less likely to follow if the patella were left in place. Mr. Lister questioned the necessity for excision in Mr. Bird's case; he thought it would have been advisable to adopt full incision into the joint and removal of the affected parts by scraping and gouging.

Mr. BIRD had no doubt that Mr. Lister would have done as he had suggested if the case had come under him; and he could not explain why he himself had not adopted a similar course. He should say, however, that the patient had been getting progressively worse, and that there was grating in the joint, while the semi-lunar cartilages were quite unrecognisable. Had the patient been other than a hospital one, he would have recommended sea air and hygienic surroundings before operation. He quite agreed with Mr. Gant that the patella could not be saved in cases of advanced disease; and he also had secured good and useful legs after sacrificing the patella.

"BODY-SNATCHING" in Philadelphia, necessitated by the paucity of dissecting-room material, has led to the indictment of Professor Forbes, of Jefferson College, on eight counts of complicity with the resurrectionists.

OBSTETRICAL SOCIETY OF EDINBURGH.

WEDNESDAY, JANUARY 10.

Professor SIMPSON in the chair.

PATHOLOGICAL SPECIMENS.

PROFESSOR SIMPSON exhibited a case of a child born in the Maternity Hospital which died immediately after birth from ascites of the peritoneum. There was fluid in the scrotum, showing a direct connection with the peritoneum. Also a deformed foetus. Another of an acephalic foetus.

Dr. HALLIDAY CROOM read a paper entitled

SOME OBSERVATIONS ON THE BLADDER DURING THE EARLY PUERPERIUM.

After describing the relative positions and relations of the bladder and uterus in the early puerperium, he proceeded to point out the influence which filling of the bladder exerted on the uterus. Firstly, he drew attention to displacement of the uterus upwards and backwards, taking exception, however, to the term displacement, and showing that the word displacement did not exactly convey a correct impression of what actually took place. He admitted that a certain limited ascension of the whole organ occurred, but that the real heightening of the fundus was the result of the bladder as it filled straightening the uterus, and so throwing the fundus higher up, and that the backward displacement of the uterus resulted from the intestines falling down between the uterus and the anterior abdominal wall, rendering the organ thus less easily palpated. He drew attention to the experiments of Autfage and Depaul with the hysterometer, which supported the opinion that the alteration in the uterus was not a displacement of the entire organ, but a real heightening of the fundus. Reference was then made to the normal lie of the uterus, which the author showed was generally believed to be right lateral; but from the observations made by Börner, as well as his own, he was inclined to believe that the normal lie of the uterus was central, provided always the bladder and rectum were completely empty, and the patient flat upon her back. He then showed that the second effect of the bladder filling was to cause or increase this lateral deviation of the uterus, and he pointed out that the ordinarily accepted opinion as to the right deviation of the uterus with a full bladder was not borne out by his own observations. He showed that the frequency of left lateral displacement of the uterus was much more common than was generally believed, and he attributes this to the fact that the bladder distended naturally to the right side during the early puerperium, and that for two reasons:—First, because of the natural right asymmetry of the bladder of the parous woman, and second, because of *ante-partum* conditions, namely, that during pregnancy the bladder spreads out more to the right side than to the left, owing to the left occipito-anterior position of the head. The right deviation of the uterus he attributes to—first, the natural lie of that organ during pregnancy; and, second, to the rectum; and, third, to the accident of position. The third effect of the distended bladder was to affect the rotation of the uterus, increasing the rotation where it already existed, and, in cases where the uterus was transverse with an empty bladder, bringing it about. He drew attention to these displacements being more common in the early than in the late puerperium—firstly, because of the relatively greater diuresis; secondly, because of the greater frequency of retention of urine; and, thirdly, because of the greater mobility of the uterus. In conclusion, he alluded to some figures with regard to the amount of urine required to bring about these position changes, holding that while twenty to thirty ounces of urine caused these changes under certain circumstances most markedly, that these changes were not proportionately increased with double that quantity of urine.

Professor SIMPSON thought the paper well worthy of careful consideration, but was not very clear as to the rotation of the uterus mentioned by Dr. Croom. The uterus is twisted differently in the pregnant than in the non-pregnant state.

Dr. James Young, Dr. Hart, and Dr. Napier made some further remarks.

Dr. A. D. S. NAPIER (Dunbar), then read his paper on UMBILICAL CORD ROUND CHILD'S NECK AS A CAUSE OF DELAYED LABOUR, AND SOMETIMES A CAUSE OF INFANTILE DEATH, in which he maintained that coiling of the cord was the

cause of delayed labour, and was, indeed, a very common cause of delay.

Professor SIMPSON doubted if coiling of the cord was ever the cause of delay. Still, the paper was useful as directing attention to these cases.

Dr. JAMES YOUNG had had some experience, but he never knew of a case of delayed labour from shortness or coiling of the cord round the child.

Dr. GUNNING said that in Brazil the forceps are too frequently used, with much injury to the women.

Professor SIMPSON then read

THE HISTORY OF A CASE OF BASILYSIS.

This is a method for reducing the base of the skull with the basilyst, an instrument invented by himself, and which has been before described in this journal.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular

Is published every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
IF PAID IN ADVANCE 1 1 0

* Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20 King William Street, Strand, London, W.C.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JANUARY 17, 1883.

TRANSFUSION.

THIS subject has lately been brought before the profession, both in England and abroad, with some prominence; and two instruments for transfusion—widely different in character—having been quite recently introduced, it will be profitable that we should criticise them freely, as well as the principal methods of performing the operation. At the outset, the question may be simplified by eliminating from it the transfusion of blood from the lower animals, for there is an irrefragable chain of evidence which proves this treatment to be unsound in theory and very dangerous in practice. Transfusion is indicated in two distinct groups of cases. The first comprises those cases in which the operation is performed with the view of replacing blood lost, either by small, repeated hæmorrhages, or by a solitary copious discharge, perhaps followed by

continuous, though slight, flow. To arrest the hæmorrhage simultaneously with replenishing the loss by transfusion the practitioner must regard as a *sine quâ non*. The second group includes those cases where the corpuscular richness of the blood is considerably below the normal; or where the corpuscles have become vitiated by certain toxic agents. Waiving the consideration of the practical difficulties which beset blood-transfusion, as well as the appreciable risk to the donor which the performance of the operation involves, we are bound to state that it must be regarded, as it at present stands, as most unsatisfactory; for though, doubtless, many lives have been saved by it, unquestionably it has often proved directly fatal. So far as the primary result of the direct operation is concerned, the safest and best plan is to transfuse from artery to artery by means of a simple, short tube, provided with a cannula at either extremity (the instrument being filled with a saline fluid at about 100° F.). By this means the blood passes from giver to recipient with rapidity, urged onwards by a normal *vis-a-tergo*; and, should any fibrination in the tube occur, the embolus so formed, if it pass the afferent cannula, is carried toward the systemic capillaries of the recipient. Unfortunately, these comparative advantages are outweighed by the consequences which the operations on the arteries might entail.

Again, should transfusion, by means of the simple tube, be attempted from vein to vein, the *vis-a-tergo* becomes so quickly expended that the blood will coagulate very speedily within the instrument. This difficulty is only partially overcome by Dr. Aveling's well-known apparatus, which is essentially a tube plus a small dilatation or expansion, that the blood may be forced onwards by the hand of the operator. Fibrination has not seldom occurred in this apparatus; and a coagulum, once formed, may most readily be propelled into the recipient's vein by this method. The operation for inserting the afferent cannula within the vein of a patient the subject of severe hæmorrhage is greatly facilitated by the anæsthesia necessarily present as the consequence of acute anæmia. Not so in the case of the donor. Here no such anæsthesia exists, and to adapt the afferent cannula involves an exquisitely painful and tedious procedure. This, clearly, is an important objection to Dr. Aveling's method, and to those similar in this respect.

Dr. Roussel's apparatus substitutes a greater for a lesser evil; for by this method the vein is opened with a lancet enclosed within a cylinder, and the risk that important structures adjacent to the vein operated on may be injured by the phlebotome is exceedingly great. The indirect method must, for obvious reasons, be recommended in preference to the direct, if skilled assistance be scanty. But let no one imagine that the risk of coagulation which obtains in the latter is removed by the so-called defibrination which characterises the former method; for not only are the meshes of the muslin commonly employed as a filtering medium of larger size than the sectional area of the individual capillaries, but coagulation may occur even in the filtered serum. The only advantage blood-transfusion possesses over the intra-venous injection of

salines, or of some other fluids, is its nutritive quality. Let us consider what really is transfused by the indirect method. The blood is whipped immediately after it has been drawn; the process of "defibrination" withdraws the bulk of the fibrin-forming elements and many of the red corpuscles. The crassamentum is separated from the serum by filtration; and the latter, not perfectly deprived of the fibrin-forming constituents, and containing corpuscles, some intact, and others broken up, with their hæmoglobin liberated, is injected into the recipient's vein. What nutritive value can such a fluid possess? Mr. Jennings' suggestion that, for the treatment of anæmia the result of severe hæmorrhage, the intra-venous injection of saline fluid is, on the whole, infinitely preferable to blood-transfusion (as the means for its performance now stand) seems a right one; for those dangers, already referred to, which are peculiar to the latter, cannot exist in the former method. Once more we would point out most unequivocally that in the treatment of this, the first group of cases, the primary benefit of transfusion lies in its dynamic action. Now the functions of circulation, absorption, and assimilation (which were impaired or arrested prior to the transfusion) are restored; and this result can be obtained with greater certainty, and far less danger, by the transfusion of a comparatively large quantity of a saline fluid than of a small quantity of blood. The patient rallies, and the stimulus imparted by the operation can usually be maintained by means appropriate to the exigencies of the individual case. A well-regulated dietary and the exhibition of ferruginous preparations, with good hygienic surroundings, will afford the pabulum for the reproduction of new red corpuscles. Mr. Le Page has devised an elaborate modification of Dr. Aveling's instrument, which exaggerates, in place of diminishing, the defects of Dr. Aveling's. Mr. Le Page claims that with his transfusor the blood in its passage can be accurately estimated as to quantity. We need scarcely remind the reader that to know how much blood, in drachms or ounces, has been transmitted in a given case can serve no useful purpose; and in this instrument the object is attained by a complex mechanism which must considerably increase, in comparison with Aveling's apparatus, the risk of fibrination. Mr. Le Page appears to disregard also the fact that the dilatation in the latter instrument having a known capacity, the quantity of blood transmitted can most readily be determined by it. The diverticulum, or air-receiver, in Le Page's transfusor would also serve as an additional focus for coagulation. These facts have already been pointed out, and Mr. Le Page has not yet replied to them. Nor has he answered the searching question as to whether this instrument has withstood the crucial test of clinical trial.

Mr. Jennings' "syphon" is an instrument specially intended for the intra-venous injection of saline fluid, or for defibrinated blood, if this method be desirable. Charged with fluid, the entrance of air to the syphon is impossible; the cannula is specially devised to promote ease of introduction of it into the vein operated on, to which air cannot gain access if the cannula when in situ be so maintained by a

ligature. This instrument seems well calculated to serve the purpose it professes—and which, indeed, it has fulfilled—an easy, safe, and expeditious means for an important operation. By a modification of this apparatus, referred to in our columns, Mr. Jennings states that it is applicable for immediate blood-transfusion, "abolishing" the risk of fibrination, and "minimising" the danger to the blood-giver. Should this modified instrument answer the expectations claimed for it, it will be doubly valuable as an adjunct to the practitioner's *armamentarium*.

PASTEUR AND KOCH.

At the late International Congress at Geneva, Pasteur delivered an address giving the results of his experiments on the etiology of infectious diseases in animals (fowl cholera, splenic fever, rabies, and glanders), and took occasion during the address to make an attack on his German rival. For the reason that he did not like to reply in what was to him a strange language, and for the further reason that he wished to make his ground as secure as possible by further inquiry, Koch postponed his rejoinder until a more convenient season. He has now given his reply in a pamphlet of thirty-seven pages, published by Fischer, of Kassel and Berlin. The standpoint he takes is that "it is not yet proved that all infectious diseases are parasitic in their nature, but that the parasitic character must be proved in each separately." He then goes on to show how an investigation ought to be carried out in order to arrive at an absolute proof, and cites his experiments on the tubercle bacillus as a series to which exception cannot be taken. He calls attention to Pasteur's experiment with the saliva of dogs dead of rabies, and with mucus of the nostrils of horses dead of glanders, without considering what these secretions are composed of, and without satisfying himself beforehand that microbes really existed in them. Further, that rabbits have been inoculated with the nasal secretion from cases of glanders, when in reality no man knows whether rabbits are susceptible of the poison of true glanders, although there can be no doubt that such inoculation does produce a new disease not unlike the septicæmia that can be produced in rabbits by inoculation with almost any kind of decomposing material. In regard to the discovery of the cause of splenic fever, Koch claims the priority for himself, inasmuch as he showed the development of anthrax spores and their relation to the disease in 1876, whilst Pasteur did not publish his discoveries until 1877. With regard to the alleged immunity of fowls from anthrax, on account of the high temperature of their blood, Koch has proved the incorrectness of the statement, whence it follows that he cannot place any value on the subsequent one—that they may be rendered susceptible by lowering their temperature. Pasteur's belief is that anthrax spores develop in the buried bodies of animals that have died of splenic fever, and that they are brought to the surface by earth worms, whence they are brought into contact with the food. This, according to Pasteur, must, in order to produce infection, be of a prickly kind, so that animals partaking of it are wounded in the mouth. The disease is

then produced by a kind of inoculation of the oral cavity, and Pasteur considered this proved by the fact that, in all animals attacked by spontaneous splenic fever, the submaxillary glands were invariably swollen. Koch, on the other hand, believes that anthrax bacilli can grow independent of the bodies of animals, the remains of dead plants, and form their spores. They live, therefore, most likely in marshy neighbourhoods, at the surface of the ground; and experience has shown that animals are frequently infected in localities in which anthrax cadavers never have been buried. Moreover, as militating against the earth-worm theory of Pasteur, may be mentioned the fact that, in lands in which anthrax causes the greatest devastations, the surface temperature is exceedingly low, as in Siberia. He has also experimented with earth-worms actually containing numerous anthrax spores, and the results reached were not favourable to the acceptance of Pasteur's hypothesis. His own experiments lead him to believe that the prickly nature of some kinds of fodder has no part in the production of the disease. With regard to preventive inoculation, Pasteur, after the first successes, held it to be "beyond a doubt that not only sheep, but that also all kinds of animals susceptible of splenic fever could be rendered immune against it; that it further seemed to him to be a settled thing that all other infectious diseases should behave like anthrax, and that their peculiar microbes could be weakened and changed into a protecting inoculation material." Löffler, however, arrived at the following results from his experiments at the Imperial Health Office:—"That there really are bacteria diseases, which, attacking an individual once, render him proof against a second attack; but there are, on the other hand, not a few similar diseases which may attack the same individual twice within a short space of time, and which thus afford no protection against subsequent infections." Erysipelas, gonorrhoea, and relapsing fever have been shown by Löffler to be infectious diseases, depending on the presence of bacteria, and may be mentioned as examples of the latter class of diseases, to which may now be added tuberculosis. Moreover, even in such diseases as fowl cholera and anthrax, Koch will not admit the high value of preventive inoculation that has been placed upon it by Pasteur. In his opinion, "Pasteur's preventive inoculation, on account of the insufficiency of the protection afforded by it, against the natural infection, on account of the evanescent character of such protection as it does afford, and on account of the dangers the practice of inoculation give rise to both amongst human beings and unprotected animals, cannot be characterised as practically of any value. It must not be understood by this, that preventive inoculation has no future before it, but that the method proposed by Pasteur is burdened by these drawbacks, and for this reason is impracticable. Other improved methods may, perhaps, in the course of time, do that which in too hasty a manner has been expected of this imperfect method of procedure." Thus far, Koch has had the last word. It is perfectly clear, however, that the controversy cannot stand where it is, and that it is one that can be decided only by facts brought to light by experiment and verified by the scientific world at large, or at least by a sufficient number of capable observers to place the result arrived at beyond the reach of cavil.

Notes on Current Topics.

Clinical Society of London.

THE annual meeting of the Clinical Society was held on Friday evening last, when, in addition to the usual business, the secretary's and treasurer's reports were read, and office-bearers for the ensuing year elected. The treasurer's statement was a most satisfactory one, the balance in hand amounting to £160 2s. 2d.; while during the past twelve months an addition of £50 has been made to the invested funds of the Society, these now standing at £550. A sum of more than £80 has been expended also in connection with the new diplomas of honorary membership recently issued by the Society; the principal item being an outlay of fifty guineas for a special seal die engraved by Messrs. Wyon, of Regent Street. The secretary reports that the numerical strength of the Society is likewise well maintained; and in all respects it is in the most flourishing condition possible.

Among the votes of thanks to the retiring officers the principal was that offered to Professor Lister, on completion of his two years' occupation of the presidential chair. The task of proposing this fell to Mr. Gant, who discharged it with feeling and eloquence. He referred to the early association he enjoyed at University College with Mr. Lister, and to the subsequent devotion of the latter to pursuits which culminated in the creation of antiseptic surgery. He described in well-chosen terms the later success of Mr. Lister's labours, and concluded by referring to the important papers contributed to the Society's Transactions by the retiring president during his term of office. Mr. Marsh seconded the motion, which was warmly and unanimously accepted. Mr. Lister's reply was a brief expression of gratification at the constant assistance rendered him by the secretaries and council and members of the Society. He could not but think, however, that the success was less attributable to the efforts of its president than to its own inherent vitality and the unwearied zeal of its honorary secretaries, a tribute which was echoed by the hearty way in which the thanks of the meeting were accorded to the secretaries.

Hospital Administration Charges.

THE annual balance sheets of several of the larger metropolitan hospitals afford unmistakable evidence of a fast impending monetary crisis in connection with them. Very serious increase of expenditure over income has taken place during the past year at most of the institutions dependent for support on voluntary contributions. The principal of these is King's College Hospital, where £9,000 has been spent in excess of the charity's income. St. George's and Westminster likewise figure, but to a less extent, and the question naturally arises, "To what is the deficiency due?" It has been suggested that in recent years, not only have the numbers who seek medical treatment at hospitals undergone very large increase, but also that the average cost of treatment is greater. These facts would both seem to be demonstrated, and if it be so, then it must be evident that unless a more generous support is given to hospitals in the future, the usefulness of these institutions must necessarily be cur-

tailed in correspondence with the limits of their respective resources. We cannot, however, avoid a suspicion that other causes also have assisted to bring about the net result; and at King's it is more than remotely probable that the nursing system has acted injuriously on the income of the charity as well as in other ways. It is no longer a secret that the eight years during which the St. John's Sisterhood have had control of the nursing department at King's have been years of disaster for the hospital, and quite recently the committee demanded either the institution of necessary reforms in nursing, or the restitution of their own power in the wards, a power that should never have been relegated to a foreign body. The dissatisfaction created in connection with the nursing arrangements at King's has naturally spread beyond the hospital, and influenced the direction of public charity, as seems only too clearly shown by the deficiencies referred to above. Whether, again, people give less freely to hospitals now than was the case prior to the institution of Hospital Sunday is another matter. It is, of course, possible that the person who formerly sent his guinea or £5 note to the secretary will now prefer to leave it in the church collecting-box, and that if by chance he do not attend church on the particular day his donation will be entirely lost; but, on the other hand, it may fairly be presumed the late trade depression has materially and directly influenced the amounts of charitable subscriptions everywhere. It is much to be hoped, however, that this period is now well past.

Last Year's Medical Publications.

MESSESS. SAMFSON LOW and Co. announce in their *Publisher's Circular* that during 1882 there were 119 new works and 58 new editions of books on medicine and surgery and associated subjects published. In the year preceding, the numbers were 108 and 56 respectively. These figures are, after all, not so considerable as might have been expected from the activity displayed by publishers and authors, judged by the announcements in weekly and—in spite of the College of Physicians' "resolution"—daily papers. It would, notwithstanding, be possible to enumerate the volumes of permanent value in the list in a far less space than would seem to be indicated by the fact of new editions of 58 works having appeared.

Royal Commission on Irish Prisons.

THE warrant nominating the Royal Commission to inquire into the administration, discipline, and condition of Irish prisons, both local and convict, was published in the *London Gazette* of Tuesday, January 2. The Commission will be presided over by Sir R. Cross, M.P., and will consist of the following:—The Hon. W. St. John Brodrick, M.P. (eldest son of Lord Midleton); E. R. Wodehouse, Esq., M.P. for Bath; Dr. Robert M'Donnell; Dr. George Sigerson; N. D. Murphy, Esq., late Member for the City of Cork; and T. A. Dickson, Esq., M.P. Major A. B. M'Hardy has been appointed secretary to the Commission. The specific matters into which the Commission is directed to inquire are (1) the recommendation contained in the report of 1879, presented by the Commissioners appointed to inquire into the working of the Penal Servitude Acts, and the desirability of adopting and

carrying out the same in the Irish prisons. (2) The working of the recent amalgamation of the administration of local and convict prisons in Ireland. (3) The independent inspection by visiting committees of local justices or otherwise. (4) Whether the safe custody of persons confined in local prisons is adequately and efficiently provided for. (5) The points of difference at present existing between the prison systems in England and in Ireland, and the desirability of rendering the two systems as nearly as may be uniform.

Glanders.

IN examining microscopically, in the Imperial Health Office, Berlin, sections from the cadaver of a horse killed on account of glanders, Dr. Löffler and Professor Schütz discovered a delicate rod about the size of a tubercle bacillus. This they cultivated, until the cultivation had been carried through four generations. From this fourth generation of purely cultivated bacilli, a small quantity was inoculated into the nasal mucous membrane and into the shoulder of a healthy old horse. The animal began to be very feverish forty-eight hours afterwards, and at the point of inoculation ulcers developed, from which knotted lymphatic cords could be felt running to the tracheal and withers glands, so that in about eight days the horse presented all the appearances of a typical case of glanders. After the horse had recovered it was killed and sections were taken from the enlarged glands. Similar bacilli were found in these, which were again subjected to "pure" cultivation for four generations, after which rabbits, guinea pigs, and white and field mice were inoculated. The evidence from some of these was merely negative in character. Afterwards two healthy horses were inoculated with the purely cultivated bacilli. These became infected and died of glanders, and post-mortem examination revealed the changes characteristic of the disease.

Massage as practised by Barbarians.

AN article in the *Popular Science Monthly*, by Dr. Graham, contains a quotation from Mr. Charles Nordhoff's book on the Sandwich Islands, describing a practice which he found prevalent among the natives under the name "lomi-lomi." Writing in 1873, he says: "Wherever you stop for lunch or for the night, if there are native people near, you will be greatly refreshed by the application of what they call 'lomi-lomi.' Almost everywhere you will find some one skilful in this peculiar, and, to tired muscles, delightful and refreshing treatment. To be lomi-lomied, you lie down on a mat, loosening your clothing, or, undressing for the night, if you prefer. The less clothing you have on the more perfectly the operation can be performed. To you thereupon comes a stout native, with soft fleshy hands, but a strong grip, and beginning with your head and working down slowly over the whole body, seizes and squeezes with a quite peculiar art every tired muscle, working and kneading with indefatigable patience, until, in half an hour, whereas you were sore, and weary, and worn out, you find yourself fresh, all soreness and weariness absolutely and entirely removed, and mind and body soothed to a healthful and

refreshing sleep. The old chiefs used to keep skilful lomi-lomi men and women in their retinues; and the late king, who was for some years too stout to take exercise, and was yet a gross feeder, had himself lomi-lomied after every meal as a means of helping his digestion."

Suicide of a Surgeon.

AN inquest was held last week on Mr. C. R. Johnstone, resident surgeon at the Cheltenham Dispensary. He had suffered from pain in the head, for which he had taken chloral for relief, occasionally as much as ninety grains. On Friday night he took two doses, and his wife afterwards discovered him shaking something else, which he said was ether. Afterwards the deceased asked her to pray for him, and he died in a few minutes. Medical testimony showed that the deceased had taken prussic acid. A verdict of "Suicide while in an unsound state of mind" was returned.

Medical Wills.

AMONG the wills proven last week were those of four members of the profession, i.e., Sir James Alderson, M.D., F.R.S., formerly President of the London College of Physicians, under a personalty of £15,000; Mr. Annerly Allcock, M.R.C.S., late of Smethwick, under £9,600; Dr. John Francis de Grave, late of Croydon, under £33,000; and Dr. Samuel Newington, late proprietor of the Titchhurst Private Lunatic Asylum, under £10,000. Of these, Dr. de Grave bequeaths £5,000 to the Court of the London Society of Apothecaries, to be applied to the maintenance of decayed members. No reference is made to medical charities in the other wills.

The Certificate Regulations of the Irish College of Surgeons.

OUR columns to-day contain an advertisement by which the Council of the College calls special attention to the regulations as to attendance on lectures and at hospital which were promulgated by them last June. These regulations have been already printed by us in full, and circulated by the College to every school and hospital in Ireland, but, from recent occurrences, it would seem that this method of bringing collegiate ordinances under the notice of students is insufficient, and the Council has, therefore, been obliged to resort to the public press to make its rules known. It is, in fact, more than suspected that ordinances which interfere with the interests of school and hospital teachers are carefully concealed from the students, as was done when the Council declared its disapproval of night lectures. We, therefore, take the occasion to direct the special attention of Irish students to these regulations, which they can have on application to the College Registrar. By them, the student is required to attend a given proportion of each course of lectures and of each hospital session, and will certainly be refused examination if his certificates are not up to the mark in this respect. Moreover, if untruthful statements be made in his certificates as to the number of attendances, the student is himself personally answerable for the mis-statement. He will be required to attest the

entries in his schedule, and, if it be found that such entries are incorrect, he will at any time be liable to have his diploma revoked and his name struck out of the list of College Licentiates. A very serious responsibility is thus imposed upon the student, and we think it our duty to call special attention to the matter in order that no disappointments may arise where certificates come to be produced prior to examination.

Royal College of Surgeons' Museum.

THE Museum of the Royal College of Surgeons of England, which has been closed for some months past, was re-opened for general use on Monday. On the preceding Saturday afternoon a large number of Fellows and Members of the College accepted the invitation of the President to a private view of the renovated collection, and a reception was held during the afternoon from three to five. The museum has been carefully re-arranged, and cleaned and painted, and the preparations remounted where necessary. We shall give a full account of the changes shortly.

The Royal Irish University.

THE standing committee during their meetings last week agreed to recommend to the Senate that certain changes shall be made in the literary portions of the arts courses for the examinations to be held next autumn. The committee also agreed upon the changes in the present courses for arts, which they will recommend to the Senate to be brought into operation in the year 1884-5. The committee resolved that examinations for the degrees of M.D. and M.Ch., and for the diploma in Obstetrics, and also for the Second University Examination in Medicine, shall be held next June. The committee had under consideration a memorial from the matriculated women students of the Royal University, praying that arrangements may be made to accord them facilities for receiving instruction from the Fellows of the University. The memorial was referred to a special committee for consideration and report.

Notice has been issued to all the members of the Convocation of the Royal University that a meeting is to be held on Thursday, the 1st of February, 1883, at 1 o'clock p.m., for the purpose of electing a clerk of Convocation, and of framing rules for conducting and registering the proceedings of Convocation, including the election of Senators, and for concurring in the table of fees fixed by the Senate as payable by members of Convocation.

THE recent serious outbreak of hydrophobia at Whitton has again drawn attention to this subject, and those numbers of the *Medical Press* which contained a series of special reports from the pen of Dr. Dolan, of Halifax, have again been sought for in vain. These numbers have for some time been out of print, and upon inquiry we learn that the book which was subsequently reprinted by the author from our columns is also out of print. But the leading points adduced and deduced therefrom will be fresh in the memory of many of our readers, and enable them to give an authoritative opinion from personal experience to the correspondent who asks for information in our present issue.

The Dublin Branch of the British Medical Association.

THE sixth annual general meeting of the Branch will be held on Thursday, 25th January, at four o'clock p.m., in the Hall of the King and Queen's College of Physicians. The officers and council for the ensuing year will be elected by ballot, and any other necessary business transacted. Dr. Banks, President-elect, will deliver the annual address, and Dr. Mahomed, Physician to Guy's Hospital, will attend the meeting, and explain the objects of the Committee of the Association (of which he is secretary) for the Collective Investigation of Disease, and the functions of the Local Sub-Committee of the Branch recently formed in connection therewith. The annual dinner of the Branch will be in the College Hall, at seven o'clock p.m., on the day of the meeting.

Hydrophobia.

A SERIES of important investigations have been made by M. Pasteur in the virus of rabies. Not content with having discovered it in the saliva, he has tracked it to its source—the centre of the nervous system. The brain appears to be excessively charged with virus, and to be peculiarly sensitive to inoculation. Such inoculation surely causes death, while it has been demonstrated that inoculation through the blood by a bite, or otherwise, is by no means invariably fatal. In the course of his experiments, M. Pasteur made the important discovery that a dog who recovers after such inoculation is incapable of "taking" the disease a second time—in other words, is proof against rabies. He has at present four dogs in this condition, and concludes that, as man never contracts rabies except from the bite of a mad dog or other inoculated animal, it may not be impossible to devise means for protecting him against such accidents. Such a discovery, if reducible to practice, may serve to protect not only mankind, but dogs themselves from the dreaded disease, the mere mention of which causes a panic among their masters. In many cities, notably New York, whole hecatombs of dogs are offered up at the first whisper of rabies; for of all diseases hydrophobia seems to be that most capable of inspiring such terror in the human breast as to steel it against every pleading of gratitude or mercy.

ACCORDING to the returns now made up, 3,340 students matriculated in Edinburgh University last year, being an increase of 103 on the preceding year. Of these 1,730 were medical students.

THE *Official Messenger* publishes a decision of the Medical Council of St. Petersburg, condemning the homœopathic remedy for diphtheria, which has lately been tried there in the hospitals of the Red Cross Society, as false and dangerous.

DR. BUNSEN, the German chemist, has been elected a Foreign Associate of the Paris Academy of Sciences. The dignity is one of the highest in the scientific world, and is limited to eight names. Dr. Bunsen succeeds the late Professor Wöhler, of Göttingen.

THE Army Medical and Transport Inquiry Committee sat again at the War Office on the 10th inst., the Earl of Morley presiding. The examination of medical officers who had had charge of field hospitals and sick transports occupied the whole sitting.

FOR the year 1883 the Academy of Medicine, Paris, offers seventeen prizes, the total amount of money being over 60,000 francs. The largest prize is one of 25,000 francs (£1,000), which will be given to any one who, in the judgment of the Academy, has found a remedy, against diphtheria.

HER MAJESTY has been graciously pleased to nominate the following gentlemen to be Companions of the Order of the Indian Empire:—Surgeon-Major James Edward Tierney Aitchison, M.D., Indian Medical Department, Bengal; and Surgeon-Major George Bidie, M.B., Indian Medical Department, Madras, Superintendent of the Central Museum at Madras.

NOTICE has been given that examinations of candidates for fifteen commissions in the Medical Department of the Army, and for twelve vacancies in the Medical Department of the Royal Navy, and five appointments in the Indian Medical Service, will be held at the London University, Burlington Gardens, on the 19th February next, and following days, at 10 o'clock a.m.

MR. CHRISTOPHER HEATH, F.R.C.S., has been elected a Member of the Court of Examiners of the Royal College of Surgeons of England, to fill the vacancy caused by the retirement of Mr. Luther Holden, late President of the College. At the same meeting of the Board, Mr. John Wood, F.R.C.S., was elected a Member of the Court of Examiners in Dental Surgery.

DR. WILLIAM J. SMYLY has been appointed to succeed Dr. A. V. Macan as Gynæcologist to the City of Dublin Hospital, Dr. Macan having been—as we recently announced—appointed Master of the Rotundo. Dr. W. Smyly was for some time Assistant-Physician to the Rotundo, and a Demonstrator in the School of the Irish College of Surgeons.

SOME time ago Miss Baxter, of Balgavies, and Dr. Baxter, Procurator-Fiscal, of Dundee, gave jointly £150,000 for the endowment and erection of a college in Dundee. The necessary buildings have now been acquired, and professors having been appointed, the work of the college will soon commence. Miss Baxter has within the last few days given £10,000 more to provide a laboratory, and the trustees of the late Dr. Baxter an additional £10,000 to endow a chair of law.

DR. S. D. CLIPPINGDALE, whose papers on Hip-joint Disease are at present appearing in the *Medical Press*, was last week presented with a testimonial, consisting of a gold keyless chronometer and a handsome card-tray. The subscribers, who numbered nearly 300, were chiefly patients, and accompanying the testimonial was a bound volume containing their names.

THE Secretary of State for War has approved the appointment of Deputy Surgeon-General J. A. Marston, M.D., C.B., lately employed as Sanitary Officer with the Egyptian Expedition, to be Head of the Sanitary and Statistical Branch of the Army Medical Department at Whitehall Yard, in succession to Deputy Surgeon-General J. Irvine, M.D., who has proceeded to Egypt to relieve Surgeon-General Sir James Hanbury, K.C.B., in medical charge of the army of occupation.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 37, Bombay 25, Madras 33, Geneva 25, Brussels 23, Amsterdam 24, Rotterdam 39, The Hague 19, Copenhagen 20, Stockholm 31, St. Petersburg 39, Berlin 22, Hamburg (State) 23, Dresden 21, Breslau 28, Munich 30, Vienna 24, Prague 33, Buda-Pesth 22, Trieste 22, Rome 24, Venice 30, New York 22, Brooklyn 23, and Baltimore 34. No returns were received from Paris, Christiania, Naples, or Turin.

In the large towns last week the highest annual death-rates per 1000 of the population from diseases of the zymotic class were—From whooping-cough 2·9 in Glasgow, 1·4 in Manchester, and 1·7 in Cardiff; from measles, 1·3 in Liverpool and 2·3 in Cardiff; from scarlet fever, 1·6 in Leeds and 1·8 in Sheffield; and from "fever," 1·0 in Bolton and 1·4 in Liverpool and in Blackburn. The 47 deaths from diphtheria included 21 in London, 13 in Glasgow, 4 in Edinburgh, 3 in Manchester, and 2 in Portsmouth. Small-pox caused 5 deaths in London, 4 in Newcastle-upon-Tyne, and 2 in Oldham.

WITH a rise of temperature and drier weather, the rates of mortality last week in the principal large towns of the United Kingdom showed a considerable reduction. Classified according to the healthiness of these towns, the deaths per 1,000 were:—Halifax, Birkenhead, 15, Bradford, Cardiff 16, Bristol, Nottingham, Derby 18, Newcastle-on-Tyne, Norwich, Portsmouth, Bolton, Birmingham 19, London, Salford, Leicester 20, Brighton, Plymouth 21, Sheffield, Preston, Huddersfield, 22, Edinburgh 23, Wolverhampton 24, Oldham, Leeds 25, Sunderland, Hull 26, Manchester 27, Blackburn 29, Liverpool 30, Glasgow, Dublin 31.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

DUNDEE ROYAL LUNATIC ASYLUM.—At a quarterly court of the directors of this institution, held on the 10th inst., it was shown that a heavy debt is at present due to the Union Bank of £49,876 on the building account. The erection of the new asylum had been undertaken on the faith that about £60,000 would be got for the site and buildings of the old asylum. A revaluation of the property for the satisfaction of the Union Bank, which was to advance the necessary loan, was afterwards made of close upon £50,000. The loan had now been exhausted, and a considerable sum expended beyond that, and the interest payable on that account was so large that the directors were not likely to be able to meet it from their free surplus revenue.

A MONTH'S VITAL STATISTICS.—From the Registrar-General's returns for the past month we learn that there were registered in the eight principal towns of Scotland the births of 3,444 children, of whom 1,795 were males and 1,649 females. Of these 3,148 were legitimate, and 296 illegitimate, being in the proportion of 1 illegitimate in every 11·6 births, or the illegitimate births constituted 8·6 per cent. of the whole. In Perth 5·6 per cent. of the births were illegitimate; in Leith, 5·7; in Greenock, 6·1; in Paisley, 7·2; in Aberdeen, 8·5; in Glasgow, 8·8; in Edinburgh, 8·9; and in Dundee, 11·4 per cent. During the same period 3,001 deaths were registered, of whom 1,469 were males and 1,532 females. This number is 85 above the average for December during the last ten years, allowing for increase of population. From diseases of the zymotic class, whooping-cough was the most fatal, having caused 153 deaths, or 5·1 per cent. of the whole mortality; 7·7 per cent. of the deaths in Dundee were attributed to this cause. The deaths from inflammatory affections of the respiratory organs (not including consumption whooping-cough, or croup) amounted to 864, or 28·8 per cent. Those from consumption alone numbered 257, or 8·6 per cent. 74 deaths were attributed to violent causes, of which three were suicidal. One death resulted from delirium tremens, and 5 from the direct effects of intemperance. One male and ten females were aged 90 years and upwards, the oldest of whom were, a crofter aged 96, and a widow aged 96.

PROFESSOR GRAINGER STEWART.—We regret to have to announce that Professor Stewart is still confined to his bed at the Bridge of Allan, suffering from a severe attack of rheumatic fever. When we last made inquiries the Professor was reported to be somewhat better, but still unable to leave his bed.

MUNIFICENT BEQUEST TO THE EDINBURGH ROYAL INFIRMARY.—We understand that Mr. Thomas Laing, of Linhouse, West Calder, has left the residue of his estate, which it is estimated will amount to over £30,000, to the Edinburgh Royal Infirmary.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 6th inst., was 101, and the death-rate 23 per 1,000. Diseases of the chest accounted for 52 deaths, and zymotic causes for 10, of which 2 were due to fever, 2 to diphtheria, and 4 to scarlatina, the intima-tions of these diseases for the week being 10, 3, and 26 respectively.

THE DEATH-RATE OF GLASGOW.—The death-rate in Glasgow for the week ending with Saturday, the 6th inst., was 31 per 1,000 per annum, against 33 in the preceding week, and 27, 31, and 27 in the corresponding periods of 1882, 1881, and 1880.

FRESH OUTBREAK OF FEVER AT DUMFRIES.—For a few weeks Dumfries was free from fever, but again it has broken out. On the 8th inst. a woman was sent to the Infirmary, and on the following day four persons from one family, suffering from fever, were sent to the same institution.

BANFF.—TESTIMONIAL TO DR. MANSON.—On the 10th inst., Dr. A. G. Manson, of Banff, was entertained at a banquet in the Council Chambers of the Town Hall, and at the same time presented with 500 guineas and a magnificent silver tea tray. Provost Williamson presided, and there was a large company present. The principal toast was proposed by Sheriff Scott-Moncrieff, who also, in the name of the subscribers, made the presentation to Dr. Manson, who, he said, had begun in 1835 the practice of his profession in the parish of Forgue, Aberdeenshire, where he became known as a very skilful physician, and in many respects a most estimable man. He remained in the district for a

quarter of a century, after which he came to Banff. The amount subscribed for the testimonial was £500 10s., in subscriptions ranging from 1s. to £35, and the subscribers, of whom there were over three hundred, included representatives of all classes of the community. Dr. Manson, in returning thanks for the handsome gift, and also for the expressions of goodwill towards himself, spoke in terms of high gratification in regard to the kindness which he had experienced from all with whom he came in contact since he came to Banff.

EDINBURGH.—ANTI-VIVISECTION MEETING.—The annual meeting of the Scottish Society for the Total Suppression of Vivisection was held on the 10th inst., under the presidency of the Rev. Dr. Adamson. The secretary read the annual report, which stated that the movement was continuing to make satisfactory progress over the country, though a large amount of indifference still existed regarding the cruelty which the practice of vivisection caused to animals. During the year between 50 and 60 petitions had been presented to Parliament from Scotland calling for the total suppression of vivisection. These petitions contained over 30,000 names, one from Edinburgh containing nearly 20,000, and one from Leith with over 5,000 names, besides petitions from the Provost and Magistrates and Council of Dundee, and also from Glasgow and other places. The treasurer's statement showed that the income had been £173 13s. 2d., and the expenditure £184 4s. 3d. There was the customary mixture of "goodness" and "invective" in the speeches which followed, the chairman winding up with the very serious statement—if true—that "he had been authorized to state that at that moment £15,000 was being withdrawn from the University of Edinburgh in consequence of Professor Rutherford's practice of vivisection."

QUESTIONABLE ADVERTISEMENTS.

On the title-page of the last number of the *British Medical Journal* (January 13th) will be found the following advertisement:—"Bladder and Prostate in both Sexes. By David Jones, M.D., Founder of, and Physician to, the Home Hospital, Dean Street, Soho. The work contains illustrated diagrams of the cure of *stone without cutting*, pain, or danger, and numerous successfully-treated cases hitherto regarded incurable." Our attention having been drawn thereto by several correspondents, we sought in vain for name and qualifications of the said David Jones, M.D., both in the official Medical Register and the London Medical Directory. Would our contemporary inform us of the legal standing of "Dr." Jones, or whether the foregoing advertisement is considered of such a nature as to be entitled to receive the *imprimatur* of even the advertising columns of the official organ of the British Medical Association? Perhaps some of our readers can throw light on "Dr." Jones of the Home Hospital, Dean Street; if so, we shall feel obliged.

GAMBETTA'S DEATH.

PRINCIPAL official history, the *Union Medicale* gives the following particulars upon the best authority:—The wound of Gambetta, received on the 27th November, resulted from the bullet of a revolver, which entered by the palm of the hand and went out by the dorsal face of the forearm. It was almost completely healed by December 10th, but on the 18th, after a copious meal, he felt a severe pain in the right hip,

which lasted about half-an-hour, and disappeared gradually. For many years past this pain manifested itself frequently about an hour after eating, and Gambetta was in the habit of pressing the hand strongly over the region of the liver, when the pain gradually disappeared. The frequent repetition of the pain had accustomed him to carry the palm of his hand in this position. On this particular occasion the spot remained painful for a longer period. On the 16th he received several friends and felt fatigued; in the evening he experienced a rigor, temperature went up to forty centigrade, and the abdominal pain became more acute. During the following days the symptoms of perityphilitis showed themselves about the region of the ascending colon. The inflammation then extended to the abdominal wall and iliac fossa, gangrene supervened, and death ensued on December 31st. Diabetes was suspected, but not found to exist, but albuminuria was detected at each examination. At the autopsy made forty-eight hours after death, putrefaction of liver and kidneys prevented exact diagnosis. Recent inflammation of peritoneum was discovered in neighbourhood of ascending colon, with sub-peritoneal inflammation of the entire right hypochondrium, principally about the large intestine. Two large phlegmonous deposits were found in the costo-iliac space, with old adhesions between the thickened gall bladder and angle of colon, and between the vermiform appendix and cæcum. There were no deposits of pus—not more than two spoonfuls altogether; but the most important lesion found was an old stricture of the lower part of ileum and ileo-cæcal valve, so tight that the end of the little finger could barely get through. This stricture was evidently the cause of the pain which was felt in the left side after eating, when the food was passing from the small to the large intestine, and it became more violent during convalescence, because a careful dietary had been observed during the healing of the wound. He returned too quickly to his habitual régime. In short, the cause of death was, firstly, a wound of hand and forearm, cured; and secondly, intestinal obstruction causing phlegmonous inflammation in the locality of an old intestinal stricture in an obese subject, albuminuric, and perhaps diabetic, running into gangrene and death. The thoracic organs were healthy. The brain, of which the circumvolutions were perfectly normal, only weighed 1,160 grammes—somewhat under average. It was supposed that a syphilitic taint existed, but no trace of the diathesis was found, either during the illness or after death.

Correspondence.

THE PREVENTION OF HYDROPHOBIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The recent outbreak of hydrophobia at Whitton, in Radnorshire, directs attention to this terrible complaint, for which, at present, there is no certain remedy. A plan for the prevention, or, at least, mitigation of the disease, was introduced and put into practice some twenty years ago by M. Bourrel, of Paris, and this plan has since been reported favourably upon by Mr. Fleming, the eminent President of the Royal College of Veterinary Surgeons, in his work on "Rabies and Hydrophobia," p. 360-361. Bourrel's method, which has been successfully practised, consists of blunting the canine teeth and incisors of young dogs. This operation renders it impossible for a dog to inflict wounds on men or animals which might lead to inoculation with the virus of rabies. The treatment imposes no restraint upon the animal. "Bourrel's proposal," says Mr. Fleming, "has never been carried into general practice as far as I know, but it will be seen that it is by no means an unreasonable one; and in countries where dogs are particularly susceptible to rabies, or

during an epizooty of the disease, it might, and, indeed, must prove of the greatest utility. Even in ordinary circumstances, with vicious dogs it would be most injudicious not to resort to it to prevent their doing mischief."

Bourrel's experiments in this direction commenced in 1862, and were conducted upon thirty dogs. When the permanent teeth are well grown he states that the dog may be so disarmed. The operation occupies about eight minutes. There is no subsequent derangement of health, and the creature eats as well as before. The teeth are no more exposed to caries than they were previously; the lips conceal them except in aggression or defence, and the beauty of the dog is not impaired. "In general," says M. Bourrel, "it is a sharp pinching produced by the front teeth that causes inoculation; the skin is torn, or the bite draws blood. By blunting, or resection, sixteen obtuse surfaces are substituted for sixteen sharp points. Sporting dogs in the habit of tearing the game have been prevented from doing so by this measure, while the furious disposition of some dogs, such as watch-dogs, which render them dangerous to every one, was softened, and brutes which would have to be destroyed were consequently allowed to live. Terriers have not ceased to kill rats after this blunting; they have only lost their power to kill cats, which is a happy result. The same operation disarms those bull-dogs that certain individuals have the discreditable passion of exciting to fight; pet dogs have been operated upon without any inconvenience."

Granting that in rare cases sporting dogs would be deteriorated by this process of reducing their fangs, or even that exception should be made in their favour, there can be no doubt that, were the system applied to pet dogs, mongrels and other curs of low degree, who are, after all, the most fruitful causes of hydrophobia, the number of victims to that terrible disease would be reduced.

Apart from the absolute danger arising from a dog's bite, the sense of nervous apprehension and suffering to the victim is a serious evil. Bourrel's proposals excited a great amount of ridicule at the time they were brought forward, one journal suggesting that all dogs should be provided with false teeth; and no doubt, were the French physician's plan generally adopted, we should hear a great deal from certain emotional hobby-hunters about cruelty to animals. As a rule, however, this class of busybodies care more for pets and curs than they do for humanity.

With a view of eliciting information, I shall feel obliged if you will find space for this somewhat long letter.

Yours, &c.,
A MEMBER OF THE SANITARY INSTITUTE
OF GREAT BRITAIN.

Literature.

ESSENTIALS OF VACCINATION. (a)

DR. HARDAWAY'S work has come at a very opportune moment, as it gives very precise information on the practice of animal vaccination in the United States, and many important statistical tables to prove the importance of vaccinia as a preventive of small-pox. We strongly advise all who wish to know what can be said for and against vaccination to read it. Dr. Hardaway discusses at some length the question of the origin of vaccine, and decides in favour of its being mitigated variola. In Chapter V. he gives an excellent account of erysipelas, which rarely is caused by humanised lymph, and, it is said, never is caused by animal lymph. He also alludes to some other vaccinal eruptions, and among others to *vaccinia gangrenosa*, eczema, generalised vaccinia, and vaccinal syphilis. Chapter VI. treats of re-vaccination, and discusses the question, what constitutes a successful re-vaccination? He recommends it at puberty. In Chapter VII. our author speaks of humanised and animal vaccination, mentioning, by the way (p. 71), that animal vaccination has almost entirely superseded humanised in the United States, so that the relative merits of the two kinds of lymph are no longer spoken of. He asks whether the preventive power of vaccination has degenerated, and mentions that in 1802 a Committee of the House of Commons could only hear of two cases of small-pox after vaccination. "Even as late as thirteen years after the

practice was introduced no fatal case of small-pox after it had been heard of." So that Jenner thought small-pox might be stamped out by vaccinators. But he concurs with Dr. Cameron in thinking that vaccine is much less powerful now as a preventive, for the proportion in which vaccinated children are attacked and cut off by small-pox has greatly increased of late years as compared with the commencement of the century. On the other hand, Martin, of Boston, and Warlomont, of Brussels, say that animal vaccine is perfectly protective against small-pox, and that it does not deteriorate as humanised lymph does. It cannot convey syphilis, can be had in unlimited quantity in times of epidemics, and is free from erysipelatos infection. In Chapter X. our author quotes Macaulay, that the small-pox in the seventeenth century was comparable in its ravages with the plague. From 1783-99 one-tenth of the total mortality at Berlin was caused by it. In a single year it destroyed 100,000 Indians in Quito. In 1721 one-half of the population of Boston, U.S., were attacked, and one-thirtieth of them died. Even with humanised lymph, he says, Dr. Buchanan (*Med. T. and G.*, June, 1881) has shown that in 1880 there died in London from small-pox 1,532 persons of all ages, of whom 325 were certified to have been vaccinated, 637 as not vaccinated, and 570 belonged to the "not stated" class. Dr. Buchanan calculates that in London in 1880 there were 3,620,000 persons vaccinated, and only 190,000 unvaccinated, and he calculates from this that the death-rate from small-pox of all ages of the vaccinated was 90 per million, and 3,350 per million of the unvaccinated. Again, of those living under five years of age he finds the mortality to have been 40½ per million of the vaccinated, and 5,950 per million of the unvaccinated, so that even in its supposed degenerated state humanised lymph is a great preventive of small-pox. Lastly, our author speaks of the dangers of vaccination, and shows that small-pox was formerly a great cause of scrofula, which vaccination avoids. As to tuberculosis being communicated by animal vaccine, he alleges with truth that this can neither be affirmed or denied with our present knowledge. Compared with the millions of favourable cases, the one or two accidents arising from vaccination sink into insignificance, and we might as well give up railway travelling on account of accidents as abandon vaccination because it, like chloroform, sometimes causes a death.

A TREATISE ON THE THEORY AND PRACTICE OF MEDICINE. (a)

TWELVE hundred and eighteen most excellent pages truly but why placed between a single pair of covers whence they are sure rapidly to extricate themselves if subjected to the not over-careful treatment too often accorded the volumes of the medical students' library? This and other works of similar proportions would be much more handy and durable if published in two volumes. The favourable impression produced by this admirable treatise is amply proved by the fact that, among so many competitors, it has run through three editions since its first appearance six years ago. The present edition is brought well up to date, containing corrections, new matter, and additional woodcuts.

The pages relating to the legal management of lunatics, which include a copy of the necessary certificate with full explanations and instructions thereon, will be found especially valuable, as containing information not always easily accessible to those who may be unexpectedly called on to deal for the first time with such cases.

In these days of pathological bacilliology we read with satisfaction the guarded language of the author on the subject of the "Tubercle Bacillus" in the "Addendum," p. 1,173, where he says: "It is scarcely justifiable perhaps to assert at the present time that the bacilli discovered in tubercle have been absolutely proved to be the cause of tubercle. But it must be admitted that the evidence in favour of that view is very strong. Nor, even if this relationship be established, does it necessarily follow that tubercle is an infectious disease any more than ague is infectious. Still, the probability of its direct or indirect infectiousness becomes much increased. The parasitic origin of malignant disease remains to be discovered."

FREQUENT HÆMORRHAGE FOLLOWING FRIGHT.

M. MERRER reports that a deaf and dumb child of 14 years of age, having been very much frightened by a fire, was affected some days after with violent bleeding of the nose, which lasted 24 hours, notwithstanding the application of iron to it, and the use of the perchloride of iron. The indocility of the patient at first prevented the use of Belloc's probe, but afterwards it was possible to use it, because of an approach to syncope. The epistaxis had scarcely ceased when it was followed by vomiting of fresh blood, proceeding, doubtless, from the stomach, which resisted the application of ice for 24 hours, and was in its turn succeeded by coughing, causing a bloody expectoration. This last accident was successfully overcome by ergot of rye, and the child soon recovered its usual health.

PILOCARPIN IN POLYURIA.

In a recent memoir (*Thèse de Paris*), M. Dugroux asserts that pilocarpin by hypodermic injection, in the dose of one-sixth to one-third of a grain, has proven successful in some forms of polyuria. It brought about complete cure in two cases of azoturic polyuria, the one essential and the other symptomatic of interstitial nephritis; in this last case it also caused the disappearance of very marked amblyopia. In two cases of simple polyuria it caused a notable amelioration of the general symptoms. It proved unsuccessful in a case of polyuria in chronic saturnine poisoning, in a chronic case of simple polyuria, and in a case occurring to a patient in an advanced state of scrofulous cachexia.

GOOD NEWS FOR TEETOTALLERS.

WITH regard to the home consumption of wines, spirits, and beer last year, the records show that the consumption of imported wine was nearly 8 per cent. less last year than the preceding year, and 9 per cent. less than in 1880; in imported spirits the decline was at the rate of 1½ per cent. on 1881; in home-made spirits, for which the returns are only made up for nine months, the decrease was 1 per cent. Allowing for increase of population, the rate of decrease in the home consumption of spirituous liquors is very marked. At the same time there has been a remarkable growth in the consumption of tea. So far, last year compared with the preceding, the growth has been at the rate of 3 per cent.; in cocoa it was 8 per cent.

The Council of the London Model Abattoir Society proposes to consider the electric with other painless methods of slaughtering animals. Meanwhile it is pointed out that the suggestion for rapid killing of animals by means of electricity has already been tried. Some years ago Dr. Richardson made use of the large induction coil at the Royal Polytechnic Institution for testing the question, and killed several sheep and other animals by the electric shock. The experiments led to results which were to a certain degree promising, and to a certain degree disappointing. The electric discharge always succeeded in striking the animals into instant insensibility, and in many instances killed them outright; but in other instances, after the temporary production of all signs of death, there were indications of recovery, so that death had to be completed by other means.

DR. CORVISART, who was physician to Napoleon III., and the Prince Imperial, died suddenly, on the 24th ult., at his residence in the Champs Elysées, aged 71. He was nephew of Baron Corvisart, physician to Napoleon I., who died of apoplexy when he heard of the defeat of Waterloo. The Baron just deceased attended Napoleon III. at Chislehurst on his death-bed.

Medical News.

Liverpool Medical Institution.—The following is a list of office-bearers for 1883 elected at the annual meeting of this Society on January 9th:—President: Mr. J. Shadford Walker. Vice-Presidents: Mr. E. A. Browne, Dr. W. Macfie Campbell, Mr. Rushton Parker, and Dr. H. G. Rawdon. Honorary Treasurer: Dr. J. Barr. Honorary General Secretary: Dr. Frederick Pollard. Honorary Secretary to ordinary meetings: Mr. F. J. Paul. Honorary Librarian: Dr. J. E. Burton. Council: Dr. W. Alexander, Dr. R. S. Archer, Dr. W. Carter, Dr. T. Clarke, Dr. A. Dunbar, Dr. T. R. Glynn, Dr. J. Lambert, Mr. W. McCheane, Mr. J. K. Smith, Dr. S. Spratly, Dr. J. H. Wilson, Dr. A. Wiglesworth.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

DR. FRY.—We regret that we cannot accept the article for publication in our columns. It is too conspicuously written in defence of private interests; and even though all the statements were capable of rigid proof, they would be fitted only for the advertisement pages of the journal.

PROPOSED VACCINATION CONFERENCE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I regret to have to differ with your correspondent in reference to the proposed Conference. I have received one of the circulars referred to in your last issue, and am of opinion that such a question cannot be settled in the way proposed, nor will truth be thereby elicited. It may suit the anti-vaccination party to have this opportunity of airing their views at a Conference, which I have no doubt will be largely patronised by that party.

Mr. Makuna seems to object to official intrusion into this Conference. This is a mistake. Who are so well qualified to speak on this subject as the officials at Whitehall, who have had to deal with the vaccination of this country?

I am in favour of another Royal Commission—similar to the one which sat in 1871.

Yours faithfully,
OBJECTOR.

Yorkshire, Jan. 11th, 1883.

DR. E.—We are obliged for the information, and beg you to accept our best thanks for the frank and friendly intimation afforded in your letter. It is, of course, sufficient to know of the existence of the intention. It is now clear what course should be followed, and the note shall be speedily forwarded.

GRATUITOUS ATTENDANCE ON SERVANTS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of the 3rd inst. you quote, in answer to "Senex," from Greenwood's "Laws affecting Medical Men" the following passage: "A master is not bound to provide medical assistance for his servant." Perhaps you would be kind enough to refer me to the heading under which the passage above quoted is to be found, as I possess a copy of Greenwood's, but cannot find your quotation.

Yours very truly,
FELIX.

Jan. 3rd, 1883.

[The passage we quoted was not from Greenwood's book, but from "Laws affecting Medical Men," by R. G. Glenn, LL.B., p. 195.—ED.]

DISPENSARY MEDICAL OFFICERS AND RAILWAY SOCIETY PATIENTS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Is a dispensary doctor expected to visit railway society patients on dispensary or visiting tickets when the porters, watchmen, &c., &c., have a society amongst themselves, with their own medical officer appointed to attend to them and their families?

In case a ticket was issued to one of the above-mentioned, can the doctor refuse to attend?

I am, yours, &c., &c.,

Jan. 5th, 1883.

ONE EXTORTED ON.

[The case stated is a manifest imposition upon the Poor-law medical officer; but he is, nevertheless, bound to attend. It is a question whether the dispensary committee would cancel tickets issued under such circumstances. We think they ought.—ED.]

A GENERAL PRACTITIONER.—The first case we remember to have seen recorded was by Mr. Crispin Hutchinson; but the value of iodine in the treatment of erysipelas has been recognised for the last thirty years.

DR. COGHILL.—The case was commented upon in our columns in October last.

DR. C. B., DR. J. W., & MR. F. G.—The advertisement referred to is decidedly in bad taste, and should never have been allowed into the columns of our contemporary. We have our opinions of the author of it.

ACADEMICAL DISTINCTIONS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Looking over "Whitaker's Almanack" of this year, I observed he gives the distinctive hoods of Divinity, Law, and medicine, also Music, Engineering, Philosophy, &c., granted by recognised British Universities. I should like to know what distinctive costume appertains to Members and Fellows of the Royal Colleges of Surgeons and Physicians of Great Britain and Ireland; also if Canadian professional diplomas, as M.D. and M.S. of any University or College of the country, can be legally registered here?

Yours truly,

INQUIRER.

London, Jan. 9th, 1883.

["* There is no distinctive hood or other costume for Fellows or Members of the various Colleges of Physicians or Surgeons except the official robes worn by Presidents, Censors, &c., when in office. University graduates only are entitled to wear the hood of the University whose degrees they hold. With reference to our correspondent's last question, on the subject of Canadian diplomas, those registrable in the United Kingdom are—the University of Toronto; Trinity Medical School, Toronto; McGill College, Montreal; Bishop's College, Montreal; Royal College of Physicians and Surgeons, Kingston; and the University of Laval, Quebec.—ED.]

DR. A. J.—Your opinion exactly coincides with that we have founded on experience; there is certainly neither cohesion nor organization among members of the Army Medical Service, and every fresh attempt to alter such an anomalous state of things is met by discouragement, if not utter indifference on the part of those most interested.

FEES FOR VACCINATION PROSECUTIONS.—"S. D." asks: When a dispensary medical officer is called upon to prove cases of vaccination defaulters at Petty Sessions—(1) To what fee is he entitled? (2) By whom is the fee payable? and (3) Does the fact of his having received no subpoena make any difference?

[Sec. 10 of Vaccination Amendment (Ireland) Act, 42 and 43 Vict., cap. 70 (page 619, "Irish Medical Directory"), says: "The guardians . . . may direct proceedings to be instituted for the purpose of enforcing obedience to the provisions of the Acts. The medical officer of any dispensary who may be required by the guardians of the union to attend and who shall attend at any such proceedings shall, in addition to his actual expenses, be entitled to receive for his remuneration for such attendance such sum, not exceeding one guinea for each day upon which his attendance shall have been required and given, as the court before whom the proceedings are had shall certify. . . . If the court is of opinion that they should be allowed, the justice or one of the justices shall ascertain and certify the amount thereof to the guardians . . . and such amount shall be payable out of the poor rates of the union. . . ."—Note, 1. That the medical officer must be "required by the guardians." Subpena is not necessary. 2. That he must have attended. 3. That the fee must be certified by the magistrates. It is payable by the guardians.—ED.]

RUSTIOUS (Epping).—There are always two ways of doing things—a right way and a wrong. You have, unfortunately, selected the wrong method in the case you describe, and the result so inexplicable to yourself is the natural consequence of the treatment adopted. It will be necessary now to recreate a granulating surface, and proceed as in dressing an ordinary open wound.

MEDIOUS.—Smoking, if only moderately indulged in, and not abused, is not productive of consequences properly described as evil. In those exceptional cases where injurious effects are attributable to tobacco, it is probable that individual idiosyncrasy will suffice to explain their occurrence, assuming, that is, that there is no excessive consumption of the weed. Pipes kept properly cleaned are by far the healthiest vehicle for the enjoyment of tobacco.

MEETINGS OF THE SOCIETIES.

SOCIETY OF ARTS.—This (Wednesday) evening, at 8 p.m., Mr. W. K. Burton, "The Sanitary Inspection of Houses."

ROYAL INSTITUTION.—Thursday, Jan. 18th, at 3 p.m., Professor Dewar, "On the Spectroscope and its Applications."

HABYRIAN SOCIETY OF LONDON.—Thursday, Jan. 18th, at 8 p.m. Annual Meeting: Election of Officers; President's Address and Conversations.

ACADEMY OF MEDICINE IN IRELAND.—Friday, Jan. 19th, at 8 p.m., Living Specimens: Dr. J. Magee Finny, A Peculiar Case of Vesiculo-Tubercular Disease of the Skin.—Mr. Arthur Benson, A Case of Chancre on the Upper Eyelid.—Specimens exhibited by Card: 1. Dr. F. J. B. Quinlan, Bacillus of Tubercle in Sputum. 2. Ditto in Lung Tissue.—2 Dr. Henry Kennedy, Urinary Calculus.—3. Aneurism of Arch of Aorta obliterating Arteria Innominate.—4. Dr. H. C. Tweedy, Heart showing Vegetations on the Mitral and Aortic Valves.—5. Dr. A. W. Foot, Drawings of Facial Chromidrosis.—Papers: 1. Dr. E. A. Hayes, "Case of Empyema treated by the Radical Method, with Notes on some Antiseptic Fluids employed."—2. Dr. J. M. Purser, "Notes of a Case of Empyema."—3. Dr. W. J. Smyly, "Sudden Change in the Colour of the Hair and Skin in an Infant."

ROYAL INSTITUTION.—Friday, Jan. 19th, at 9 p.m., Mr. E. Bosworth Smith, "On Early Life of Lord Lawrence in India."

ROYAL INSTITUTION.—Saturday, January 20th, at 3 p.m., Mr. E. Bosworth Smith, "On John Lawrence at Delhi and its Neighbourhood."

ROYAL INSTITUTION.—Tuesday, Jan. 23rd, at 3 p.m., Professor W. C. Williamson, "Primaeva Ancestors of Existing Vegetation."

Vacancies.

Bromyard Union.—Workhouse Medical Officer. Applications to be sent to the Clerk on or before Jan. 22nd.

Bromyard Union.—District Medical Officer. Salary, £106, with fees extra. Applications to be sent to the Clerk on or before Jan. 22nd.

Children's Hospital, Birmingham.—Assistant Resident Medical Officer. Salary, £40, with board, &c. Applications to be sent to the Secretary not later than Feb. 1st.

London Lock Hospital.—House Surgeon. Salary, £50, with board and residence. Applications to be sent to the Secretary on or before Jan. 23rd.

Spike Island Convict Prison.—Temporary Resident Apothecary. Salary, £118, with apartments, &c. Applications to be addressed to Chairman General Prisons Board, Dublin Castle, before Jan. 20th. (See Advt.)

Royal Surrey County Hospital.—House Surgeon. Salary, £75, with board, &c. Applications to be sent to the Assistant Secretary on or before Feb. 6th.

Appointments.

CASEY, E., M.B., C.M. Aber., Medical Officer for the Sutton District of the Freetown Union.

COTTER, J., M.D., Physician to the Cork Fever Hospital.

HADDEN, W. B., M.B. Lond., M.R.C.P., Medical Registrar to St. Thomas's Hospital, London.

JONES, W. E. F., L.R.C.P.E., L.R.C.S.E., Medical Officer, Medical Officer of Health, and Public Vaccinator for the Llanfair District of the Llanfair Union.

LOWE, G., M.B., Medical Officer for the Fourth District and Workhouse of the Forehoe Union, Norfolk.

LYNAM, E. G., M.B. C.S., House Surgeon to King's College Hospital.

MADDYVER, J. O., M.D., M.S. Glas., Medical Officer for the Broughall District of the Cannock Union.

MOULLEN, Dr., Medical Officer to Gorey Infirmary.

O'BORKE, C. T. J., L.R.C.P.E., L.M., L.R.C.S.I., Medical Officer, Medical Officer of Health, and Public Vaccinator to the Crossakel Dispensary District, County Meath.

RYAN, J., L.R.C.P.E., L.R.C.S.I., Medical Officer for the First District of the Northsack Union.

RYAN, J. N., M.D. QUI., L.R.C.S. Ed., Medical Officer for the Weymouth District of the Weymouth Union.

TIZARD, H., M.D. St. And., M.R.C.S., Medical Officer for the Melcombe Regis District of the Weymouth Union.

Births.

CRIBB.—Jan. 6th, at Bishop's Stortford, the wife of Henry Cribb, L.R.C.P. Lond., of a daughter.

DOLAN.—Jan. 9th, at Horton House, Halifax, Yorks, the wife of T. M. Dolan, F.R.C.S.E., of a son.

Deaths.

CULLMORE.—Dec. 27th, at Yole Grove, co. Wexford, John B. Cullmore, L.R.C.P., L.R.C.S. Ed., Medical Officer, Fethard Dispensary District, aged 81.

FOX.—Jan. 7th, Francis Ker Fox, M.D., of Brialington House, near Bristol, aged 79.

FREEMAN.—Jan. 9th, at his residence, Stowmarket, Spencer Freeman, M.R.C.S., aged 79.

LYON.—Jan. 6th, at 276 Bath Reservoir, Glasgow, James George Lyon, M.A., M.D., aged 48.

PRIOR.—Jan. 4th, suddenly, at his residence, Donnington House, St. Albans, E. H. Prior, M.D., L.R.C.P., J.P., aged 87.

SPULL.—Jan. 6th, at Essex House, Hammermith Road, Barnard Spull, F.R.C.S., L.S.A. Lond., aged 80.

WYBRANTS.—Jan. 1st, at Shepton Mallet, Jonathan Wybrants, M.D., aged 66.

ON

THE TREATMENT OF SOME OF THE FORMS OF VALVULAR DISEASE OF THE HEART. (a)

By A. ERNEST SANSOM, M.D., F.R.C.P. Lond., Physician to the London Hospital; Senior Physician to the North-Eastern Hospital for Children, &c.

LECTURE I.—ENDOCARDITIS.

The Rational Bases of Treatment—Morbid Anatomy—Clinical Investigation—Origin and Progress of Endocarditis—Study of Endocarditis occurring in Children—Pathogenesis—Existing Methods of Treatment—Preventive Treatment.

(Continued from page 48.)

SUCH is the evidence—the important evidence, as I estimate it—to be obtained as to the rise and progress of endocarditis from the clinical observation of the cases occurring in children. It becomes us, however, to revert to the general subject, to the disease as it is seen in adults, and to inquire whether there are any other diseases with which we find endocarditis associated. In many acute fevers—typhoid, for example—it is so rare that I consider it most probable that some other factor must have been in existence in the cases in which it has been observed. In *diphtheria* it has been said to be frequent. M. Labadie Lagrave has described it as occurring in fifty cases out of 100. In this country, however, observers have, so far as I am able to ascertain, noticed no such association: certainly, I have not myself, and I cannot refrain from concluding that special features (might it have been a relation with scarlatina?) marked the epidemic cases of which M. Labadie Lagrave has so carefully recorded. (a) I cannot help thinking that the term *diphtheritic*, as applied to ulcerative or necrosing endocarditis, has been productive of confusion.

An association between septicæmia and endocarditis has been noted, and also, as my own experience has confirmed, with puerperal conditions. M. Lancereaux recorded five cases in which it was thus observed: "In all these cases,"

he says, "the valvular affection manifests itself with characters of striking similarity; localisation to one portion only of the diseased orifice, exuberant vegetation, termination by necrosis, and ultimate phenomena of infection. (b) In fact, this is a variety of the ulcerative endocarditis which we shall hereafter consider.

And now let us approach the question of the *pathogenesis* of endocarditis. Excluding the ulcerative form, which we can more conveniently discuss subsequently, and the form which is secondary to arterial degeneration (because I think it will scarcely be denied that the endocarditis is here due to the involvement of adjacent endocardium in the sub-inflammatory changes which are an essential feature in the aortic disease), there remains the large class, which includes the exudative and the sclerosing forms which I have described. These are, I consider, from their clinical and pathological characters, to be grouped together as the *rheumatic form* of endocarditis, the sclerosing being the chronic form of the exudative.

Now I think that our clinical evidence has taught us that such endocarditis may arise in an extremely insidious manner; that it may give no evidence of its rise and progress by signs nor symptoms, nor even by rise of temperature. It may probably be in existence at the very earliest period of an attack of rheumatism, fever, and even with great probability precede it unnoticed (for such may be the significance of the muffled or prolonged first sound heard at the earliest period of such disease). Moreover, it may progress *after* the attack of rheumatic fever, causing gradual retraction of the valve in a patient who may have been discharged from treatment as free from cardiac complication. Such is the disease, insidious in onset, course, and character, the causation of which we have to consider. However occult its origin and course, we must allow that the inflammation of the endocardium is an integral part of the rheumatic process, that it is produced by the same agency which in many cases, though not in all, produces inflammation of the fibrous textures of the joints. Such morbid agent is, without doubt, distributed by the blood. The question occurs, Is it introduced from without or developed within? The view of its extrinsic nature has been forcibly argued lately, especially by Dr. MacLagan. (c) The hypothesis

(a) Des Complications Cardiaques du Croup de la Diphthérie. Paris, 1873. Cf. Morrell Mackenzie, "Diphtheria," p. 64. London: J. and A. Churchill. 1879.

(b) "Anatomie Pathologique," p. 537. Paris: Victor Masson et fils. 1871.

is that the *materies morbi* which produces it is a form of malarial, and as such, is of the nature of a living, probably a fungoid, organism. Against such a view is, I think, the point which I have brought forward as so strongly borne out by observation—that endocarditis is not a pyrexial disease. Our knowledge of the action of low organisms upon the living body tells that they give rise to fever. It is, to my mind, highly improbable that proliferating germs introduced into the blood should cause an inflammation of the endocardium and yet fail to increase the general temperature of the blood. Moreover, the hypothesis fails to explain, as I consider, many of the phenomena which are explained by the other, viz., that the origin of the *materies morbi* is from within.

Let us consider, therefore, the second proposition—viz., that the endocarditis as well as the other phenomena of rheumatism are due to a perverted retrograde metamorphosis of tissue. The evidence seems to me to point this theory as the true one. First, we have hereditary proclivity; this, I consider, obtains not only as regards rheumatism in general, but endocarditis in particular. Secondly, proximate causes—those which I consider proven are sudden exposure to cold, the influence of certain acute specific diseases. What characterises these acute specific diseases—scarlatina and measles? An implication of the skin in a morbid process in both; of skin and kidneys in one. All such causes have one character in common—the production of an impediment to elimination. In a large number of instances I agree, of course, that proximate causes are not in evidence. In the next place, the proved conditions of the disease. An extremely acid sweat is excreted; lactic acid has been demonstrated in it, but it is not proved that lactic is the only acid thus excreted. Certainly there must be some other agent to communicate the peculiar odour which the perspiration manifests. Again, the urine is abnormally acid, and the saliva, which is normally alkaline, is in rheumatic conditions decidedly acid. Furthermore, the blood is abnormal, in that it contains an undue proportion of an excrementitious product—viz., fibrin; it is highly coagulable. What is not proven, however, is that the blood is acid; on the contrary, in rheumatism the blood-serum is alkaline. (a) At this step of the inquiry, experimental evidence comes to aid us. Dr. B. W. Richardson, to test the old theory of Prout that lactic acid is the pathogenetic agent, injected a solution of lactic acid into the peritoneal cavities of animals, and found undoubted evidence of the production of recent endocarditis in the valves of the right side of the heart. These observations have been confirmed by Rauch; but the conclusion that the lactic acid is the *vera causa* of the inflammation has been contested by Réyer, on the ground that endocarditis is common in dogs as an idiopathic disease. I think we may readily dismiss such an observation, from the fact that Dr. Richardson's observations give convincing proof of a recent inflammation far exceeding in prevalence the normal morbidity of the canine endocardium. And Dr. Richardson's observations have been confirmed by evidence which, though clinical, is also experimental. Dr. Balthazar Foster has shown that after injection of lactic in the human subject, phenomena in all respects corresponding with those of acute articular rheumatism were produced. "They came on when the acid was taken, and ceased when it was discontinued." (b)

This evidence, I take it, valuable as it is, is illustrative and analogical rather than direct and dogmatic. For me, at least, it shows that lactic acid can be an agent in the production alike of rheumatism and of endocarditis. But it does not prove that it is the only agent. We have no proof that the free acid exists in the blood in the disease; but yet it seems to me that we have full and sufficient proof that the normal retrograde metamorphosis is greatly altered; that the blood is changed; that in the course of metabolism many products are formed, with the result that lactic acid and other acids are excreted in abundance. Sufficient this, I think, for our present purpose. Is it not probable that the pathogenetic agents are many? I mean that there are numerous products between fibrin on the one hand and the excreted morbid acid on the other, capable of giving the irritating impulse.

One step further in this inquiry. The rôle of the nervous system in this connection may be a very important one, and we may ask whether there may not be a portion of the central nervous system specially concerned in the control of the chemical processes of metabolism, just as there is probably a

centre which regulates the temperature of the body. Dr. P. W. Latham has advanced the theory that there is such a centre—that such centre may be disturbed by external cold or by the accumulation of lactic acid in the blood. So he considers that the phenomena of rheumatism may be induced by the intraspinal change, just as the arthropathies are induced in locomotor ataxy. And if the disturbance of such centre involve also the neighbourhood of origin of the vagus, cardiac, pulmonary or pleuritic complications may be developed. (a)

I must now approach another part of my subject, and inquire concerning the efficacy of extant methods of treatment in regard to rheumatic endocarditis. It has been claimed of almost all methods of treatment of rheumatism that have been advocated that they have been efficacious in controlling or preventing the cardiac complications of the disease. The individual experience of observers has been cited again and again to prove the efficacy of this or that remedy or method in mitigating the chief danger of rheumatic fever. Yet proof of such vaunted efficacy has soon been found to be unsatisfactory, and it may be confidently asserted that no antiodotal treatment is yet known—that we have, for instance, no drug which can influence endocarditis as quinine influences ague or as mercury and iodide of potassium influence syphilis. The discussion so ably sustained in this Society during the last session, which has been fully reported, has put the claims of various forms of treatment of rheumatic fever to a numerical test. The results of treatment by rest and mint-water, by alkalis, by blistering and by administration of salicin and its compounds, were compared, and it is fair to assume that if any agent other than these had been efficient in the treatment of rheumatic fever or of endocarditis evidence would have made this apparent. The result of the discussion, which it is unnecessary to epitomise, (b) was to show a strong concurrence of testimony to the effect that the administration of salicin and the salicylates very decidedly reduced the suffering and the fever of rheumatism, but in no marked degree influenced the development of endocarditis and other cardiac complications. *Prima facie* this seems to be a strange conclusion, for one might imagine that an agent which reduced in such marked degree the pain and fever which must contribute to disturb the heart, even if it had no decided effect upon the rheumatic process within the heart, would with great probability influence for good the inflammatory process in pericardium as well as endocardium. The conclusion is forced home, however, alike by individual experience—for we find that pericarditis and endocarditis are shown by physical signs to rise and progress in patients who are fully under the salicin treatment—and by statistical inquiry from large numbers of cases treated by the salicin compounds compared with those treated in the pre-salicylic era, such as has been carefully followed out by Dr. Gilbert Smith. (c) Dr. Mac-lagan, to whom the profession and the public are indebted for the introduction of agents which have at any rate been proved to contribute to the comfort of suffering patients, himself allows that the hopes that they would ward off cardiac complications have not been realised. (d) He considers the reasons for such failure to be (1) that endocarditis has often begun in an attack of rheumatism before the sufferings of the patient have been so pronounced as to call for treatment; (2) the inflamed endocardium can never be placed in the conditions of rest which are necessary for cure. I endorse both these propositions, and will add to them.

To put the matter clinically, or practically. We observe, let us assume, a patient in a first attack of rheumatic fever. He presents (a) a murmur indicating an endocardial complication. I think I must have convinced you that such endocarditis may have arisen, not during the attack from which he was at present suffering, but from the disease acquired insidiously at any time previously. It is obvious that any remedy would fail to divert the cardiac complication in such a class of cases. Or (b) a modification of sounds or actual systolic murmurs developing at the apex make us suspect the present rise and progress of endocardial inflammation. But such may have had its commencement long before the advent of the other symptoms, for no sign will betray the gradual swelling of a valve. A swollen valve is not necessarily incompetent. On the other hand, a veritable

(a) Cf. Charcot, "Lectures on Senile Diseases." Sydenham Society's Translation. P. 162.

(d) "Rheumatism." Pekin. P. 266.

systolic murmur at the apex is no conclusive proof of endocarditis, for it may be due to adynamia of cardiac muscle. Here is a double source of fallacy in the statistics of the cardiac complications of rheumatism. Or (c) the patient manifesting no evidence of valvular impairment, is at the termination of his attack of rheumatic fever discharged as free from cardiac trouble. Sir W. Gull and Dr. Sutton have said that, "if the patients pass the first few days of the rheumatic fever without the heart becoming involved, then they do not contract heart disease during the latter part of the rheumatic attack." (a) Is such a conclusion justified? I think not. A valve may be inflamed and give no evidence of incompetence; the patient may be discharged and show no signs of cardiac trouble, but a slow process of shrinking or of sclerosis may be going on, and when the patient next presents himself there may be undoubted evidence of endocardial mischief. This is, I consider, by no means of infrequent occurrence, and is one reason why a second attack of rheumatic fever is attended with such notable numerical evidence of a highly increased ratio of cardiac complication.

For such reasons as these I think it impossible—the sources of error being so numerous—that we can get from statistical inquiry satisfactory evidence as to the efficacy of different plans of treatment in warding off endocardial disease, and I dissent from those who hold that a remedy which is efficacious in the treatment of acute rheumatism ought to show, on numerical inquiry, a favourable influence on the correlated heart disease. I consider the treatment by salicin and the salicylates, even though no good results are manifest as regards cardiac complications, to be the most favourable to the patient of all forms of treatment hitherto known.

In such case it may be legitimately asked whether I adopt an altogether pessimist view of the treatment of endocarditis. Can nothing be done? My answer is—much; but it must be in the direction of *preventive treatment*.

My own experience is strongly towards the conclusion that endocarditis is more prevalent, as well as more extensive and severe, among the poor than among the well-to-do. This question is one that might, with advantage, be put to the numerical test; we greatly want the evidence of the family practitioner to compare with that afforded by our hospital statistics. The predisposing causes to the advent of endocarditis, which, as I have shown, can arise without the intervention of obviously rheumatic phenomena, are most probably—1. Exposure to vicissitudes of temperature. 2. An irregular and improper dietary. These are the impulses to a perverted nutrition, resulting in the retention within the blood of those excrementitious products which we may call "the rheumatic poison." Attention to the clothing and proper feeding of infants and children constitutes, in my mind, therefore, the treatment of the first importance as regards endocarditis. There is no need nowadays to insist on the importance of preventive treatment as regards the zymotic diseases. This is well recognised. Is it not quite as important as regards the subtle disease we are considering? I would, whilst recognising the difficulties of such proceeding, strongly recommend the periodic medical examination of children, even though they present no obvious signs of disease.

Of no less importance is the treatment in regard to the zymotic diseases which are correlated with endocarditis—viz., scarlatina and measles. The subject of an attack of scarlatina should be watched with great care for long periods after convalescence. Moreover, the slightest sign of throat ailment, especially with children, should be looked upon with suspicion. I have no doubt whatever that in a large number of instances ulcerative tonsillitis of zymotic type occurs in children unnoticed and unknown, and that in many such a renal complication is instituted, which is also neglected. The rise of endocarditis in such case is, as I have said, not during the period of fever. I do not recognise the influence of morbid germs in *directly* occasioning the inflammatory change in the valve.

The teaching I would enforce, therefore, is that the subject of scarlatina, or of the allied forms of throat affection, should be watched, protected and dieted, and treated for periods much longer than is now usual. And as regards measles, there is, unfortunately, a widely-spread tendency to regard this as a very slight ailment that requires little or no treatment. Experience tells us, however, that it is often not only the immediate precursor of broncho-pneumonia frequently, and heart disease occasionally, but that it effects a deleterious

change upon the powers of nutrition which lasts, as in the case of scarlatina, for long periods. The subsequent treatment, therefore, of the subjects of measles should, in my opinion, be much more protracted than it is at present. Such is an outline of what I consider the common-sense treatment of the first causes of endocarditis. During its rise and progress in an attack of rheumatism I prefer the treatment by salicin or salicylate in sufficient doses (usual gr. xx. 4tis horis till subsidence of the pain and pyrexia, and afterwards the same dose thrice or twice a day). From the evidence of Dr. Isambard Owen there is a good case in favour of combining with this the administration of full doses of alkalies. (u) Vesication by application of liq. vesicatoris in the left axilla I think also of service.

It now only remains for me to allude to the clinical significance of *ulcerative endocarditis* with regard to indications for treatment. It happens sometimes that this affection arises and runs its course with little or no evidence that the endocardium is impaired. Such cases often present a strong resemblance to typhoid fever. Here treatment is of no avail, the disease is uniformly fatal. By far the most frequently the disease is engrafted, as it were, on chronic disease of the valves. It appears to me that such cases can be divided into two classes—the infective and the non-infective. In the infective cases there are extraordinary disturbances of temperature, multiple emboli, and septicæmic signs, or even abscesses. It is in such that micrococci are discovered. They are, I believe specific organisms—derived from some subtle zymotic influence or from a virus, as in the puerperal cases. It is not that the micrococci induce the endocarditis, but they complicate the already existent endocarditis by bringing about necrosis of the diseased tissue. In other cases, though nearly all are characterised by embolism, the proof of infection, and, as I think, the probabilities thereof, are wanting. In a case lately under my care in the London Hospital there was no marked pyrexia whatever, the temperature never exceeding 101° F., and for the most part keeping close to the normal. I consider it most probable that in some such cases the ulceration is induced by mechanical causes. Drs. Wilks and Moxon have pointed out that a great mass of vegetation may cause ulceration of the heart-wall by direct pressure, or a fibrinous clot swinging in the blood-current coming sharply into contact with the muscle, may by friction start an ulcer. (b) In like manner I think it very probable that a weighty vegetation, or mass of vegetations, upon a valve may by agitation in the blood-current so disturb the nutrition of the endocardium which constitutes its base as to start the process of necrosis.

The treatment of ulcerative endocarditis when once established is hopeless, but the lessons taught by a study of the cases are, I consider—(1) that more than ordinary care should be exercised to keep the subjects of valvular disease of the heart from possible sources of infection; (2) that any threatening of endocarditis should be treated by the most perfect physiological rest attainable; (3) that nutrition should be sustained to the highest degree practicable.

RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S. Eng., M.S. Lond.,
Surgeon to the London Hospital.

PART II.—*Reported Cases of Recovery—Treatment—Conclusion.*

(Continued from page 60.)

THE case under Mr. Morris (c) presents the following history:—On June 4th, 1879, W. H., 39, an upholsterer, was drinking at a public-house when a difference arose between him and another man, which they thought they ought to settle by wrestling. He was thrown with much force, and forcibly knelt upon by his opponent with both knees applied to the lower part of the abdomen. He lost consciousness for a time, and on coming

(c) *Medical Times and Gazette*, November, 1879.

(a) "Medico-Chirurgical Transactions," vol. iii., p. 80.

to, walked home—a mile, taking over an hour to do the distance. Before the encounter he had not passed water for an hour or two, and he was drinking up to the moment of wrestling. When he reached home he tried several times to pass water, but could not. Within an hour or two of getting into bed he voided a small quantity of blood. He continued his efforts, and passed small quantities of urine less and less charged with blood till it became nearly natural. Altogether, in thirty-six hours he estimated the amount voided at not more than three-quarters of a pint. At first he experienced pain at the lower part of the stomach; but this, without altogether leaving the lower regions, gradually got higher and higher up his stomach. He vomited frequently a quantity of greenish fluid. On admission to the hospital his face looked pale, sunken, and anxious; his chin was covered with a cold perspiration; his abdomen was tympanitic, distended, and extremely tender, the slightest pressure causing him to wince and cry out. Nothing abnormal was discovered *per anum*. He had micturated voluntarily with great pain and difficulty. A No. 7 silver catheter was easily introduced, and three or four ounces of clear normal urine were withdrawn, and by pressure a few blood clots were expelled. *The catheter was moved about to detect a rent, and none was found.* An elastic catheter with india-rubber tubing was fixed in the bladder. Plenty of urine was daily drawn off, at first clear, but afterwards becoming cloudy and purulent. On the 12th day after the accident the catheter was removed; the patient passed water voluntarily, and from this time made uninterrupted progress towards recovery. It must be added that thickening and hardness of the tissues in front of the bladder was observed some days after the patient's admission to the hospital. Mr. Morris regarded his case as a rupture of the bladder anteriorly, partly intra-peritoneal and partly extra-peritoneal; and he was supported in his diagnosis by all the surgeons who saw the case. The grounds for the diagnosis were these:—The patient had been drinking, and his bladder was full or moderately distended. He was knelt upon with great force. There was collapse followed by great pain, and several fruitless efforts to micturate. Only three-quarters of a pint of urine and blood were discharged from the bladder in the first thirty-six hours after the injury. On the introduction of the catheter thickening in front of the bladder was detected, and afterwards there was discharge of pus with the urine, this pus being poured through the rent into the cavity of the bladder. With the greatest respect for the opinions of so distinguished a surgeon as Mr. Morris, I cannot see adequate justification for the diagnosis propounded. It entirely rests upon the supposition that the bladder was full at the time of the injury. That the man had been drinking is most true, but equally true it is that he had passed water "an hour or two" (a very loose estimate of time) before the injury; and in all probability he was merely sipping his liquor whilst engaged in the hot argument, not gulping down the large quantities of liquid necessary to ensure the required distension of his bladder in the time between urination and the conflict. Even the patient's own account is insufficient to render it clear that the bladder contained any considerable quantity of urine, and his statements are not precise enough to be accepted without qualification. Now read the case on the supposition that the bladder had not risen above the pubes. The violent kneading with the knees—which must have produced rupture of a full bladder—contused the tissues, fascia, bladder, and peritoneum, fully accounting for the blood in the bladder, the thickening and hardening of the tissues anteriorly, and the peritonitis. The shock and depression, and the constant vomiting of greenish fluid diminished the amount of secretion of urine in the first thirty-six hours; and the mere rough estimate of the patient is not as valid as the reception of the urine into a graduated measuring glass.

Moreover, the passage of three-quarters of a pint of urine or more within the first thirty-six hours by the voluntary efforts of the patient is an unusual circumstance; whilst he was under observation in the hospital the urine removed was abundant. Pus in the urine is sufficiently accounted for, as in Mr. Page's case, by the retention of the catheter. As soon as the catheter was removed the urine cleared. If the foregoing explanation suffices, a complete rupture of the bladder, intra-peritoneal or extra-peritoneal, would be out of court; and the accuracy of touch which Mr. Morris displayed when he used the catheter to search for a rent and found it not, would be amply vindicated.

Mr. Chaldecott's (a) celebrated case remains. Though last to be considered, in point of time it commenced the series of recoveries; and has, I fear, been the cause of claims to recovery in other instances, owing to the support which it has lent to the opinion that the peritoneum is capable of tolerating and absorbing urine effused into its cavity. The case has been incompletely recorded, and runs as follows:—At midnight on the 7th of April, 1846, J. Philps, 50, wine merchant, of Dorking, *healthy and temperate* (!), having passed two or three hours at a concert, hastily crossed the street to empty a full bladder, and, the night being dark, ran against a newly-erected post, with the top of which the lower part of his abdomen came into violent contact. He fell immediately, and afterwards with great difficulty reached his home—about a hundred yards distant. Half-an-hour afterwards he was seen by Mr. Chaldecott, who found him faint, suffering from severe pain in the abdomen, feeling the desire but deprived of the power to evacuate his urine. A catheter was introduced easily and completely into the bladder, and drew off neither urine nor blood. He was kept in bed, and had hot fomentations applied. Reaction set in, attended with an increase of pain. Twenty leeches were ordered and a gum catheter passed, but still there was no urine. The catheter was used every three or four hours, but up to 2 p.m. fruitlessly. Eighteen hours after the accident—*i.e.*, at 6 p.m.—he was seen by Mr. Aston Key. The symptoms of peritonitis had then increased; the belly was painful, swollen, tender; the pulse rapid and feeble; the countenance anxious. Mr. Key introduced a catheter, and drew off one ounce of bloody urine. At 10 p.m. "2 scruples" (40 minims, ?) of liquor opii sedativus were administered, and produced in a few hours a comfortable sleep. Four hours after Mr. Key's visit four ounces of clear urine were obtained; and from this time—that is, *twenty-two hours after the accident*—the pain, swelling, and heat in the stomach and abdomen gradually declined, and the bladder was found to hold urine. The catheter continued to bring away clear urine. On the 10th the patient had a smart attack of gout—a disease to which he had never been subject. All went on well till the 13th (sixth day), when from a strong desire to be independent of the catheter, he made straining efforts to pass his water; and scarcely had he passed a tablespoonful when he felt (to use his own expression) something give way, and a burning pain all over his stomach and bowels, as if boiling water had been poured over them, and the same symptoms of faintness and distress occurred as when the accident first happened. Mr. Chaldecott saw him within a few minutes of the second attack, and withdrew a teaspoonful of urine with the catheter. The peritonitis became again acute, with the addition of excessive sickness. He was treated with fomentations, leeches, calomel, and a full opiate; and *after the lapse of four hours* the bladder was found to retain urine. He had another attack of gout, and the peritonitis gradually subsided; and he recovered completely. Mr. Chaldecott diagnosed a rupture of the bladder into the peritoneal cavity, and Mr. Aston Key concurred and gave an unfavourable prognosis. The urine, according to

(a) *Provincial Medical and Surgical Journal*, 1846.

Mr. Chaldecott, was absorbed by the peritoneum, and this absorption was the cause of the attack of gout. The wound in the bladder was under repair when it was reopened by the straining to pass water, and all the symptoms recurred. The following letter, kindly addressed to me by Dr. Todd, of Bognor, helps to elucidate the case, and will be read with interest:—

Bognor, 7th November, 1882.

Dear Sir,—I have been interested by your papers in the *Lancet* on "Rupture of the Bladder," more especially as I was acquainted with the patient of Mr. Chaldecott. He was under my care for the last fifteen years of his life; I have frequently questioned him about his accident. In the main he agreed with the report as it appeared in the *Lancet*, 1846, vol. ii., p. 376 (he always kept a copy by him, which he amused his friends with). He states that before leaving the concert room he had an urgent desire to pass water, but could not at once get out. When he did so he ran towards the yard, striking himself against a post as described. He insisted that he then felt something give way, and then became faint, &c. He was careful to distinguish the first giving way from the second on the occasion of his attempting to relieve his bladder without the catheter. He said Mr. Key was quite convinced as to the nature of the injury, and "told him he must settle his worldly affairs, as he feared he had but a short time to live." His daughter tells me he never had the gout until after the accident. Since then he had seven attacks—chiefly in the feet. I should hardly call him a temperate man; he was the landlord of an hotel, and his daughter says he used to drink the best part of a bottle of port daily, and from hints he has dropped I should think very often a good deal more. He died in 1876, in his eightieth year, from hypertrophy of the heart, chronic Bright's disease, and uræmia. For many years he suffered from chronic bronchitis; most probably gouty. I have sent you these few particulars thinking they might interest you, but more especially to draw your attention to the first sense of giving way when the patient struck the post.

I am, dear Sir,

Yours faithfully,

J. M. TODD, M.D.

In my reply to Dr. Todd I endeavoured to ascertain when Mr. Philp had last made water, and whether he had drunk anything between that time and the hour of his leaving the concert-room; and, further, the exact nature of the sensation experienced when he ran against the post. I also regretted that a post-mortem examination had not been performed and the bladder preserved, as the presence of a cicatrix would have been conclusive evidence of rupture. Dr. Todd could not give me any further particulars, and did not remember that his patient mentioned any burning or smarting sensation at the time of the accident. Mr. Philp said on receiving the blow he immediately became sick and faint; he reached his house crawling on his hands and knees. It is certainly a serious omission in the record of the case that no evidence is adduced to prove the fulness of the bladder at the time of the accident beyond the fact that the patient went across the road to make water. It should have been stated when the patient last made water, and whether he had been drinking in the interval. To describe the bladder as *full* or *distended* on the mere impression of the patient is a *petitio principii*. The sensation experienced of something having given way—not mentioned in the original account—does not appear to have been of a very definite character, and is not conclusive. The absence of both blood and urine from the bladder in a traumatic case, notwithstanding frequent introductions of the catheter in the first fourteen hours, is unusual, and there was no confirmation of the rupture by local examination or manipulation with the catheter. Whether the catheter was freely movable, or incapable of being rotated or

depressed, is not mentioned. Clearly Mr. Aston Key did not demonstrate the existence of a rent in the bladder. That the peritoneum should be capable of absorbing so large a quantity of urine as the bladder would contain when full, that peritonitis should immediately set in, and then *begin to subside in twenty-two hours* after the accident on the administration of "two scruples" of liquor opii sedativus, is a hard saying, and, to my mind, almost incredible. Nevertheless, if the bladder was really full when the patient ran against the post, it could scarcely escape a rupture, and any other explanation of the absence of urine on catheterism, as enlargement of the third lobe of the prostate, or the existence of a supplementary bladder or diverticulum, seems inadequate and improbable for more reasons than one. On the supposition of a rupture the choice lies between the sub-peritoneal, the extra-peritoneal, and the intra-peritoneal varieties, and the objections to either of the two former kinds are, in my opinion, as strong as to the intra-peritoneal rupture. Absorption of urine from the cellular tissue is not more tenable than absorption from the peritoneal cavity. But are we forced to choose between conclusions alike contrary to all probability and experience? I do not think that we are. I do not dispute the good faith of the patient, that he had a desire to make water, that he believed his bladder to be full, and told Mr. Chaldecott so. I do not accede to a suggestion made years ago by Dr. Eben Watson, that the urine escaped from the patient's urethra, without his knowledge, after the accident; but I cannot help strongly suspecting that the bladder was empty. Temporary suppression of urine—determined possibly by a chill at the concert—with irritable kidney from latent or incubating gout, would account for the phenomena. At all events, the view of suppression of urine advanced by Dr. Eben Watson, (a) although supported by arguments which Dr. Gillespie combated with some success, has not, by any means, been disproved. It is a noteworthy circumstance that neither blood nor urine was found in the bladder—not even a streak of blood on the catheter—but the bladder was absolutely empty. Nothing came away for fourteen hours. After eighteen hours Mr. Aston Key drew off an ounce of bloody urine, and then four hours later, under the influence of warmth and two scruples of liq. opii sedativus, a *refreshing* sleep is obtained; the attack begins to pass off, and clear urine is secreted. Two days afterwards the gout plainly shows itself. If suppression of urine holds good for the first attack, it equally holds good for the second, notwithstanding the subjective sensations of the patient. The term "peritonitis" must not be taken literally, but as representing the group of symptoms resulting from the incompetent kidneys and the effects of the accident. If, in spite of the considerations here adduced, the case should be quoted by surgical authorities as an instance of recovery after intra-peritoneal rupture of the bladder, there is still a suggestion to be made which would diminish the difficulty of accepting this conclusion, and that is, that the uræa may have been almost completely absent, as in the case of Bright's disease which came under Mr. Harrison's care on account of extravasation of urine, the result of a co-existing stricture. This explanation is not so satisfactory to my mind as complete suppression, but it is more satisfactory than recovery after effusion of a large quantity of normal urine into the peritoneal cavity not removed by operation. The insuperable character of the obstacle to recovery presented by urine pent up in the peritoneal cavity to the surgical mind is strikingly exemplified by a remark of Mr. Reginald Harrison, who, whilst endeavouring to uphold

(a) For Eben Watson's views see the *Edinburgh Monthly Journal* for October, 1848 and for 1849, p. 561; and for the controversy between him and Dr. Gillespie concerning Mr. Chaldecott's case, see the *Edinburgh Medical Journal* for March, 1859, p. 84, and the *Glasgow Medical Journal* for 1859.

the genuineness of Mr. Chaldecott's and Dr. Thorp's cases, unwittingly overthrows their claims. "In these cases," he says (a) "there can be no doubt that large quantities of urine were drawn off from the peritoneal cavity which, if allowed to remain, it is reasonable to suppose would have induced fatal consequences." Now it so happens that in Mr. Chaldecott's case scarcely anything was drawn off by the catheter, and the urine believed to have been poured into the peritoneal cavity is supposed to have been absorbed by the peritoneum, though not without resentment, and after two or three days incubation, to have taken the form of gout; whilst in Dr. Thorp's case a prolonged research in the peritoneal cavity only resulted in the meagre amount of less than twelve ounces of urine with a reddish tinge. In both cases the results of catheterism constitute a strong argument against the correctness of the diagnosis of intra-peritoneal rupture, and inasmuch as "it is reasonable to suppose" that a quantity of urine retained in the peritoneum "would have induced fatal consequences," and inasmuch as in both instances, if the cases were genuine ruptures, this retention certainly occurred, and the patient nevertheless recovered with remarkable rapidity, I must claim Mr. Harrison as unconsciously a strong supporter of my view that a rupture of the urinary bladder into the peritoneal cavity did not exist in either instance.

AN ESSAY UPON HIP-JOINT DISEASE.

By S. D. CLIPPINGDALE, M.D., F.R.C.S.

(Continued from page 52.)

IV.—THE MORBID ANATOMY.—(Continued.)

Changes in the Acetabulum.—The acetabulum may be the seat of the same structural changes which affect the head of the femur. The ulcerative process, however, which reduces the head, enlarges the acetabulum. Ulceration of the acetabulum varies much, both in area and in depth. In area the whole of the cavity, or only a small part of it may be involved; its margin, or its central position. The part usually affected is its upper and posterior fourth. In depth, ulceration of the acetabulum may produce either a slight erosion, a transparent thinning of the floor or a perforation. Thinning of the floor of the acetabulum, without perforation, may take place to such an extent as to produce a bulging into the pelvic cavity. This generally takes place when the patient is young and the bone soft.

Perforation of the Acetabulum may be marginal or central. Marginal perforation occurs but rarely. It may take place in any portion of the rim, pubic, iliac or ischiatic. In a case recorded by Adams, of Dublin, (b) there was a perforation of the iliac portion of the rim through which matter passed into the substance of the psoas muscle, overlying it here, and travelled upwards to the spine. Central perforations are far more common, and vary in size and in number. In size a perforation may vary from the smallest conceivable aperture, to one the size of the forame ovale. As to number, as a rule, only one perforation exists; but two or three are frequently met with, and in a specimen in University College Museum (c) there are eight. In young subjects the ulcerative process attacks the Y-shaped cartilage in preference to the bone, so that a Y-shaped perforation is produced; and, if the ulceration proceeds, it sometimes separates the three bones of which the innominate is originally composed. It will be readily understood that the round ligament is not likely to remain after perforation has taken place, and the co-existence of these two conditions is so remarkable that reference may be made to the only two specimens I have met with. (d)

(c) Prep. 807.

(d) London Hospital Museum Gcc 61, and St. Mary's Hospital Museum, A.C. 59.

Frequency of Perforation.—As to the frequency of perforation, of 223 post-mortem specimens examined, a perforation, healed, partly healed, or patent, existed in 49; so that from this, perforation would seem to occur in about 22 per cent. of the cases.

Causes of Perforation.—The two principal factors in the production of perforation are, firstly, the softening of the floor of the acetabulum by the inflammatory process, and secondly, the pressure with friction of the head of the femur. It is probable also that perforation may be produced by a mass of caseous matter in the acetabulum ulcerating on one side into the cavity of the pelvis, and on the other into the joint.

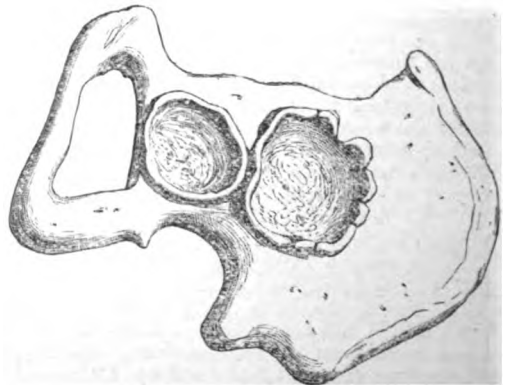

Occlusion of a Perforation.—A perforation may be closed by either membrane, lymph, or bone. Membranous occlusion is usually produced by an inflammatory thickening of the obturator fascia. A plug of lymph often occludes a perforation in the acute stage of inflammation. Bony occlusion, however, is that which is commonly met with, and this only takes place in an advanced stage of the disease.

Coexistence of Perforation with Dislocation.—As perforation is due in part to the pressure of the head of the femur, it would be expected that perforation is seldom found when the head of the femur is dislocated. In 56 cases of perforation, dislocation occurred in 4 only, and in these it probably took place after perforation had been effected.

Bi-lateral Perforation may, of course, take place when the disease is bilateral. The most remarkable case of this condition occurred in a patient under the care of Mr. John Scott at the London Hospital. In this case the abscesses from the opposite joints communicated with one another in the pelvic cavity. (a)

Diseases of the rest of the Innominate Bone.—Caries arising in the acetabulum may extend to any other part of the innominate bone. As a rule it only encroaches to some slight extent upon the dorsum of the ilium. The whole bone, however, may become involved, and in some cases the matter passes into the substance of the ala of the ileum, distending this until, as in a specimen at St. Thomas's Hospital Museum, (b) it attained the size of a cocoa nut.

Formation of a new Acetabulum generally takes place to a greater or less extent after dislocation. The new acetabulum is generally situated upon the dorsum of the ileum, above and behind the old one, but its seat of course varies with the direction of the dislocation. The old acetabulum becomes filled up; the new one is of less regular shape and larger than its predecessor, this being due apparently to movement of the bone during the formation of the new socket. The drawing below is from one of the most typical cases of formation of new acetabulum.

Clinical Records.

ST. MARY'S HOSPITAL.

Caries of the Ileum, with Abscess Cavity in the Right Loim.

Under the care of Mr. A. T. NORTON.

THE patient was admitted to the surgical wards on the 30th Oct., 1882. She complained of pain in the right lumbar region and of the hip-joint. She stated that about a month ago she felt well in the morning, but in the evening was taken with a very severe pain in the lower part of the back. On examination, she was lying upon the back, with the right leg drawn up, complaining of pain in the hip, which increased on attempting to extend the thigh, and she stated that she could not move the knee without greatly increasing the pain. This patient had been sent into the hospital for incipient disease of the hip-joint. She was very pale, thin skin, red hair, and had all the appearance of strumous diathesis. I held the thigh firmly, so that it could not move, and then flexed and extended the knee-joint without pain; then I raised the leg, flexing the thigh to a greater extent than the patient held it, and rotated the head of the femur on its socket, and forcibly pushed the head into the joint without pain. By this means I determined that the knee and hip were sound. The position in which the patient retained the thigh flexed and everted, directed me to examine the spine, suspecting psoas abscess, but I found that percussion of the spine with some violence caused no pain, and on pressing my fingers into the abdomen over the region of the psoas, I discovered an apparent tumour. The tumour occupied the posterior part of the iliac fossa, extending upwards about two inches above the level of the posterior spine of the ileum. It was painful on pressure, and by placing one hand over the right loin, and the other in front, I considered that I detected fluctuation. The temperature was now taken, and ran 103·6 in the evening, 99° on the following morning, 102·4 the next evening, and again in the morning 99°. This chart I consider diagnostic of the existence of matter, so that I could now decide that an abscess had formed in the region referred to, and it remained to decide where the pus was formed. I concluded that suppuration must be the result of either (1) caries of the spine; (2) caries of the ileum; (3) perityphlitis; or (4) perinephritis.

Caries of the Spine.—The symptoms referring the disease to caries of the spine were the interference with the action of the psoas and iliacus muscles, and the presence of suppuration; but if the spine were affected there ought to be pain on striking the region of the affected vertebræ. With so large a quantity of pus there must be active change in the bodies of one or more vertebræ, and consequent deformity of the spine, which did not exist. The sitting posture should be accompanied by pain, and the patient should have experienced for some time heaviness and difficulty in walking or sitting, but all these signs were absent. It could not, therefore, be caries of the spine.

Perinephritis.—This condition can rarely occur in an idiopathic form. It is generally consequent upon some forms of kidney disease or kidney injury. Some of you may have seen in the wards a short time ago a man who was run over, the wheel passing across the abdomen. In that case the kidney was injured, and blood flowed with the urine for two or three days in considerable quantity. After the hæmorrhage was arrested, pain continued in the left loin; then arose the symptoms of inflammation, and ultimately suppuration, the abscess opening over the crest of the ileum. In this case manipulation detected extensive enlargement in the region of the kidney, extending down the loin to near the ileum, but not projecting into the iliac fossa, like the tumour in the case under consideration.

Perityphlitis, like perinephritis, is not likely to occur as an idiopathic condition. There is usually some irritant in the cæcum—either it may be a foreign body, or chronic typhlitis from indurated fecal accumulation, with chronic constipation, or in some cases, on the contrary, diarrhoea. Then again, perityphlitis is rather a cellulitis along the cæcum, whilst this tumour was more easily detected from behind, and belonging more to the region of the loin. There was, to my thinking, an absence of the symptoms special to perityphlitis.

There remained only caries of the ileum. Such symptoms were present as would occur with caries of the ileum, an

abscess traced down into the iliac fossa interfering with the action of the iliacus muscle and taking over a month to develop itself; pain traced to and limited to the posterior fourth of the ileum by carefully indenting the finger over the crest into the iliac fossa; also, by continued pressure on the posterior fourth of the crest, œdema, or plastic exudation, with some thickening, was detected.

The only treatment that could be adopted was complete rest and the application of poultices to the region of the abscess. I did not like at this date to puncture the tumour, because I could not be sure of its relation to the peritoneum; ultimately, however, I was enabled to open it by passing the knife immediately above the crest. After the abscess was opened, the temperature chart—which had been 104° at night, and 101° in the morning—dropped about two degrees, but the discharge was profuse. In cases of caries of bone, when the cavity is not able to be exposed, and when indeed the treatment consists mainly in proper supporting nourishment and hygienic arrangements over an indefinite period of time, hospital atmosphere is decidedly injurious, and she was therefore advised to return to her home in the country.

Special.

OPHTHALMIC NOTES.

ACHROMATOPSIA IN HYSTERICAL PATIENTS.

FRENCH physicians and surgeons, as Charcot, (a) Landolt, and Galezowski, have paid particular attention to the subject of achromatopsia in hysterical patients. The following abstract of a communication by Dr. Paul Richer presents a fair view of the phenomena observed in this interesting class of cases. Dr. Richer tells us that Galezowski has shown that the amblyopia of hemianæsthetic hysterical patients is habitually accompanied by general or partial achromatopsia, and M. Landolt has laid down certain laws according to which in this sense perversion acts. Landolt believes that in a normal subject all parts of the field of vision are not equally apt to perceive various colours; in other words, the field of vision is physiologically more extended for some colours. Thus, blue has the greatest visual field, yellow coming next, then orange, red, green, whilst violet is only perceived by the most central parts of the visual field. Charcot recognises numerous exceptions to the rule laid down by M. Landolt. In the patients on whom he experimented red was found to have the greatest extent of field, then in invariable order, yellow, blue, green, and lastly, violet. In hysterical amblyopia these characters of the normal state were modified. In a patient in whom red is in the normal state, the following phenomena are observed: The violet circle disappears, and the patient, distinguishing all other colours, is incapable of distinguishing violet, then progressively, green, blue, yellow, and finally red disappear. In the highest degree of hysterical achromatopsia all the colours cease to be perceived, the notion of form and design being preserved. The phenomena of the disappearance of colours have been the subject of the experiments of Charcot, in its connection with the influence of artificial magnets on general and special sensibility. A magnetised bar is brought near the temple of a subject suffering from general and sensorial anæsthesia, on the side of the achromatopic eye, at a distance of one or two centimetres. In some seconds, or in fifteen or twenty minutes, we can follow step by step the successive reappearance of colours in this eye, precisely according to the order indicated in the degree of the extent of visual field. Thus the colour first appears in the field which offers the greatest extent of view, most frequently red, then in turn yellow, blue, green, and lastly violet. At the same time, the eye at first achromatopic recovers the notion of colour, but

(a) *Progrès Medical*, Nov. 22nd, 1879, page 914.

the other eye becomes affected in an inverse order. This is called the phenomena of transfer. But once transfer is obtained and vision of colour restored to the achromatopic eye, whilst it has disappeared in the sound eye, the experiment is not terminated; what are termed consecutive oscillations then occur. Whether the magnet be maintained or not in the first situation, the notion of various colours soon disappears according to the order indicated, commencing with violet and finishing with red in the eye primarily affected, and reappearing in the inverse order in the eye primarily sound. These phenomena oscillate from one eye to another for a variable length of time, the patient finally returning to her primitive condition. The following case more fully explains the nature of the phenomena:—

(Charcot and Richer.) Maria X., hystero-epileptic, hemianæsthetic on the left side and achromatopic on the same side, achromatopsia not complete. She has perception of red in both eyes, but the left eye cannot distinguish yellow, blue, green, or violet. Nov. 3, 1878.—One of the poles of an artificial magnet was placed near the left temple, about a centimetre from the skin. The right eye was closed with the hand and the left eye alone was observed. She distinguished only red with this eye; all other colours presented to her appear as white or grey. On passing successively before her variously coloured papers, about the end of the third minute of application she distinguished yellow; then vision of other colours appear in the following order:—

1. *Oscillation*.—In 3m. 30s. vision of blue; in 5n. vision of green; in 6m. 30s. vision of violet. At this time she possessed in the left eye vision of all colours, but in consequence of the phenomena of transfer she cannot distinguish any colour with the right eye except red. Observation continued with the left eye. Very soon, in spite of the application with the magnet, colours disappeared precisely in the inverse order. At 9m. 10s. violet disappeared, at 9m. 20s. green, at 9m. 30s. blue, at 9m. 40s. yellow, red persisting. The patient was now in the primary state, but oscillations commence as follows. These oscillations are noted only in the left eye:—

2. *Oscillation*.—Return of yellow, 11m. 40s.; return of blue, 12m. 0s.; return of green, 12m. 35s.; return of violet, 13m. 0s. Disappearance of violet, 14m. 40s.; disappearance of green, 14m. 45s.; disappearance of blue, 15m. 0s.; disappearance of yellow, 15m. 25s. Red persists.

3. *Oscillation*.—17m. 10s. return of yellow; 18m. return of blue; 18m. 40s. return of green; 19m. 25s. return of violet. 20m. 50s. disappearance of violet; 21m. disappearance of green; 21m. 20s. disappearance of blue; 24m. disappearance of yellow. Red persists.

4. *Oscillation*.—At 24m. 25s. return of yellow; at 24m. 50s. return of blue; at 25m. 30s. return of green; at 25m. 55s. return of violet. At 27m. 15s. disappearance of violet; at 27m. 21s. disappearance of green; 27m. 50s. disappearance of blue; at 28m. disappearance of yellow. Red persists.

5. *Oscillation*.—At 30m. 45s. return of yellow; 31m. 20s. return of blue; 31m. 30s. return of green; 32m. return of violet. At 33m. 15s. disappearance of violet; at 33m. 15s. disappearance of green; 33m. 35s. disappearance of blue; at 34m. disappearance of yellow. Red persisting.

6. *Oscillation*.—36m. 10s. return of yellow, 38m. disappearance of violet; 36m. 35s. return of blue, 38m. 10s. disappearance of green; 37m. 10s. return of green, 38m. 20s. disappearance of blue; 37m. 30s. return of violet, 38m. 40s. disappearance of violet. Red persists.

7. *Oscillation*.—40m. 10s. return of yellow, 43m. 15s. disappearance of violet; 40m. 40s. return of blue, 43m. 35s. dis-

appearance of green; 40m. 50s. return of green, 43m. 50s. disappearance of blue; 41m. 10s. return of violet, 41m. 0s. disappearance of yellow. Red persists.

8. *Oscillation*.—51m. 30s. return of yellow, 54m. 20s. disappearance of violet; 52m. 15s. return of blue, 54m. 30s. disappearance of green; 53m. 0s. return of green, 54m. 50s. disappearance of blue; 53m. 15s. return of violet, 55m. 0s. disappearance of yellow; 56m. 10s. disappearance of red.

At this time for three minutes the patient is totally anæsthetic and achromatopic in both eyes, but very soon the colours re-appear.

9. *Oscillation*.—60m. 25s. return of red, 65m. 10s. disappearance of violet; 61m. 35s. return of yellow, 65m. 30s. disappearance of green; 62m. 20s. return of blue, 66m. 0s. disappearance of blue; 62m. 50s. return of green, 66m. 25s. disappearance of yellow; 63m. 10s. return of violet. Red persists.

10. *Oscillation*.—The vision of all colours persists now in the right eye for nearly three minutes, transfer to the left eye; at 38m. 20s. all the colours disappeared.

11. *Oscillation*.—At 39m. 20s. all the colours appeared; at 44m. all disappeared. Experiment finished. The subject of these experiments was particularly susceptible to the æsthetic agent; it was sufficient to apply the magnet near the hand to modify the sensibility of all the side of the body, and at the same time to affect vision.

What is the value of these experiments? There is great difference of opinion as to the same, as Gamgee (a) assigns no importance to them, whilst the French savants swear by them.

This form of achromatopsia might be confounded with Daltonism, but it differs from it. The colour-blind mistakes one colour for another, as green for red, whilst the hysteric achromatopic loses completely the notion of colours. She sees objects coloured "white" or "grey," but never has an erroneous perception of colour.

To be continued.)

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

OBSTETRICAL SECTION.—FRIDAY, DECEMBER 22ND.

The PRESIDENT in the Chair.

OPENING ADDRESS.

DR. DENHAM, after some preliminary observations, took for the subject of his inaugural address "The Progress made in Obstetric Medicine during the last Fifty Years," selecting as the basis of his remarks a comparison of the Rotunda Hospital Reports of Drs. Collins and Shackleton with those recently published by Dr. George Johnston. Dr. Collins during his seven years Mastership had 16,414 deliveries, in which the crotchet was used 118 times, and the forceps or vectis 27 times. The number of deaths amounted to 164. Dr. Shackleton reported 13,748 deliveries, with the use of the perforator in 130 cases and of the forceps in 200 cases, and the loss of 163 patients. Dr. Johnston reported 8,908 deliveries; 28 craniotomy, 90 version, and 750 forceps cases. He lost altogether 169 patients. Commenting on these figures Dr. Denham observed that it was patent that by the more frequent use of the forceps in modern obstetrics much had been done for relief, without adding to the dangers of labour, and that great numbers of children were now delivered alive who under the old practice would have had to be destroyed. The beneficial results of the introduction of chloroform, the greater use of sea-tangle tents, the operation of ovariectomy, followed as it has been by so many new operative procedures, were briefly alluded

(a) "An Account of a Demonstration of the Phenomena of Hystero-Epilepsy." *British Medical Journal*, page 645, vol. II., 1878.

to as having done much to bring gynecologists into the front ranks of bold and successful operators, and to break down the barrier which at one time existed between this and other branches of the profession.

EXHIBITS.—RECENT SPONTANEOUS DETACHMENT WITH RENT IN THE SUBSTANCE OF THE RETINA.

Mr. ARTHUR BENSON exhibited a male patient showing a well-marked example of the above condition.

ACUTE PERICARDITIS FOLLOWING ON AN ATTACK OF ACUTE ARTICULAR RHEUMATISM.

Dr. G. F. DUFFEY showed the heart and pericardium of a male patient, aged fifty, exhibiting the recent pathological effects of an acute pericarditis which had lasted only for about eighteen hours.

FROZEN SECTIONS THROUGH A FULL-TIME STILLBORN FETUS.

Dr. ROE exhibited a series of these frozen sections which he had lately made—(1) Section through medial horizontal plane of foetal head; (2) section through the shoulder-joint and upper part of the chest; (3) section through the level of the third costal cartilage.

DOUBLE OVARIAN DERMOID CYSTS.

Dr. POOLE showed, for Dr. Kidd, two dermoid ovarian cysts removed from an unmarried patient, aged thirty-eight. Growth of tumour noticed for three years. The larger tumour involved the left ovary, and weighed on removal about six pounds. It is composed of numerous loculi of various sizes, some containing glairy mucoid fluid, and other masses of sebaceous matter mixed with hairs. Hard centres of ossification felt in portion of cyst walls; one of the larger cysts contained a matted mass of long dark hairs, on removing which a mass of bone was found jutting sharply into the cavity and bearing on its apex two closely-united teeth. The smaller tumour belonged to the right ovary, and is seen to consist of two cavities, one containing sebaceous matter with a few hairs, and in one part of its walls a mass of bone; the other containing a quantity of light-coloured hair and several teeth irregularly set in a bony wall.

Mr. P. S. ABRAHAM showed under the microscope preparations from above cysts, illustrating their contents and different portions of their walls.

PETO-AMNIOTIC ADHESIONS, ASSOCIATED WITH NUMEROUS DEFORMITIES OF A FULL-TIME FETUS, INCLUDING COMPLETE ECTOPIA OF THE ABDOMINAL VISCERA.

Dr. NEVILLE exhibited this specimen, and with it a four months foetus, around whose right forearm the funis had become looped and adherent, associated with deformities of both hands, &c.

CICATRICIAL OCCLUSION OF THE VAGINA.

Dr. MORE MADDEN said: At present our clinical experience of retained menstruation or impeded parturition, consequent on post-partum adhesions of the vaginal walls, is fortunately more limited than must have been the case in the practice of our predecessors, when the second stage of labour was frequently allowed to run on for twelve or even twenty-four hours, and when instrumental assistance was directed by the most eminent authorities to be withheld until the vital powers were all but exhausted. Still such cases are occasionally met with. Of somewhat greater frequency in the causation of this condition in modern practice is the opposite error of premature application of the forceps before the natural dilatation of the passage, or by the misdirected force or undue haste with which instrumental extraction may be effected. Another source of such occlusion is the abuse of escharotics for the treatment of uterine disease. Apart from these causes, the occurrence of vaginal occlusion after parturition is exceptional. The following are notes of a case of this kind which recently came under my care in the gynecological ward of the Mater Misericordiae Hospital:—The patient, aged thirty-eight, had been years married, and had given birth to four children. She never had any difficulty in parturition, and her recoveries were always rapid. Six months before admission she had a miscarriage on the fourth month. This was caused by over-exertion, and presented nothing peculiar. Up to this time her general and uterine health had been excellent. Two months after miscarrying she began to complain of obscure pelvic pain, with sense of local fullness and bearing down. Her menses did not return, and as she had previously been very regular in this respect, she naturally supposed herself to be again pregnant. The pelvic pain

increasing, however, and being now attended with dysuria, troublesome tenesmus, and obvious impairment of her general health, she sought medical advice. When admitted into hospital, her general symptoms and history suggested retroversion of the gravid uterus. On examination this was found not to be the case. The pelvic cavity was filled by a large globular tumour, which extended backwards so as to flatten the rectum against the sacrum, and upwards and forwards so as to displace the bladder. The entrance to the vagina was thus obstructed, so that the finger could only be passed in for an inch and a quarter. On bi-manual recti-abdominal exploration, the uterus was found enlarged to the size of the fourth month, but in its normal position. The patient was then placed in lithotomy position, the parts widely separated by retractors, and the seat of the obstruction, which was seen to consist of a tense, convex, fibrous-looking septum, thus fully exposed to view. This diaphragmatic-looking cicatricial structure was then punctured with a fine trocar, and a small quantity of retained menstrual fluid drawn off by the aspirator. As the fluid was too viscid to pass freely through the canula, the aperture was enlarged so as to admit the point of the finger, with which it was torn through so as to allow the gradual escape of about eighteen ounces of thick, treacle-like, catamenial matter. For two days afterwards this continued to drain away, and probably as much more escaped in this way. The membranous partition described formed the floor of a large hour-glass-shaped cavity, the lower part of which was bounded by the distended vaginal walls, communicating through the open os and expanded cervical canal with the dilated uterine cavity which formed its upper and smaller portion. On the day following the operation she had rigors, her pulse and temperature ran up, the abdomen became tympanitic, there was considerable uterine pain and tenderness, and for the ensuing week her life hung in the balance from severe metro-peritonitis. This, however, ultimately subsided under treatment. The opening was then cautiously and gradually expanded by dilators, and kept patulous by glycerine tampons until all trace of constriction had disappeared. She was retained under observation until the next monthly period, which was perfectly normal, had passed over, and being then well, was discharged from hospital. The foregoing instance of vaginal occlusion in a patient who had given birth to several children, and without any previous history of the usual causes of this condition, is interesting from the infrequency of such cases, and from the possibility of such an occurrence being an occasional cause of menstrual retention or an obstacle to impregnation or parturition. Moreover, it illustrates the danger attending the treatment of such cases, in proof of which the writer adduces the conclusion, from the observations of the principal authorities on the subject, that the treatment of cicatricial vaginal obstruction is by no means as safe as it is facile. And that the safest instrument in the removal of these adhesions is the surgeon's finger—the mortality following the use of any cutting instrument being nearly threefold that resulting from their digital separation.

Dr. ATTHILL said that the case was unique in his experience. He did not think that the occlusion could have resulted so completely from any abuse of caustics. It was probably due to the occurrence of adhesive inflammation, such as he had seen result in a like way in the case of women who had never been pregnant.

Dr. KIDD narrated the history of a case recorded by the late Dr. Sawyer, in which a cicatricial occlusion of the vagina was found as an impediment to labour at the end of her second and third pregnancies—the occlusion having on each occasion to be opened up by crucial incisions. He insisted on the impossibility of negating the co-existence of pregnancy with almost any amount of occlusion, illustrating this point by the details of many cases which had fallen under his own observation. It was often very difficult to say whether the occlusion had taken place before or after conception. Dr. M'Clintock had described a form of annular contraction due to atrophy of the vaginal walls in aged women. He (Dr. Kidd) had seen cases of a like kind in much younger women. Possibly, in Dr. Madden's case, an annular contraction of such a kind had formed, proceeding to such an extent as to form an "impermeable stricture," thus giving rise to the occlusion.

Dr. J. A. BYRNE did not think Dr. Kidd's explanation held in Dr. Madden's case. Atrophic contraction was limited to older women. Strong escharotics injudiciously

applied were, he thought, among the most frequent causes of vaginal or cervical occlusion. When retention of the menses resulted, they should be let out slowly and cautiously.

The PRESIDENT thought that coonception might occur in spite of very considerable occlusion. Occlusion did not seem to be so frequently met with now as when the forceps was less often and more tardily used.

Dr. MORE MADDEN briefly replied.

BREAKING STRAIN, OR TENSILE STRENGTH OF THE UMBILICAL CORD.

Dr. NEVILLE read a paper on this subject, founded upon 125 experiments made by him on the fresh cords of full-time children. Having explained the method of making these experiments, in which only the 12-14 inches of the cord nearest to the placenta were tested, he stated his conclusions as follows:—In 100 cords from which the blood had been allowed in great part to escape before subjecting them to strain, the average tensile strength amounted to 12.5 lbs.; one cord bore a strain of 27 lbs.; nine cords a strain varying from 20 to 25 lbs.; eighteen of from 15 to 20 lbs.; forty-eight of from 10 to 15 lbs.; twenty-three of from 5 to 10 lbs.; and one of less than 5 lbs. In the case of 25 cords tested without allowing any escape of the blood contained in them, the average breaking strain was found to be very little above 11 lbs., or nearly one and a half pounds less than in the other case. The cords belonging to male were found to have an average strength of 1.5 lbs. more than those of female children; multiparity made no appreciable difference in strength. The strain was always gradually increased until the cord broke; and rupture was most commonly found to be first marked on the outer aspect of the cord where an umbilical vein projected in a varicose manner. Thin, straight, and wiry cords, possessing a comparatively small amount of Whartonian jelly, and whose surfaces were least marked by varicose projections, habitually bore the greatest strains. The rather scanty literature on the subject was summarised; especially a paper by Pfaunkuch (A. f. G. Band. VII., Heft. 1), who studied the effects of a sudden strain caused by the falling of the child's body, if delivered when the woman was in the upright position. Dr. Neville considered the question of a gradual drag as affecting inversion of the uterus. Assuming as conditions a strong funis abutting at or near the centre of the fundus on a firmly adherent placenta, and a flaccid pliable uterus wanting in contraction and retraction, he thought improper tractions on the cord very likely to terminate in inversion. Inversion is a rare accident, because these conditions are rarely met with in combination, and because real fundal attachment of the placenta is particularly uncommon, notwithstanding text-book statements to the contrary.

Dr. MACAN considered that there could be no doubt that inversion might readily be effected by pulling on the cord under the circumstances laid down in the paper. He would lay special stress on the fact that traction, in order to result in this way, should be made at right angles to the uterine wall at the site of placental attachment. This only could happen when the placenta had a fundal attachment.

Dr. ATTHILL compared inversion as an accident of delivery, with that which resulted from an intra-uterine tumour. In the one case he believed that, as a matter of personal observation, the tumour, and in the other case the placenta would always be found attached to the fundus. The fundus was the part of the uterus most susceptible of irritation. Irritation would set up contractions, and these would expel either the tumour or placenta, and along with either might invert the uterus. Pulling on the cord might facilitate the inversion, but could not act as a sole cause of this accident.

Dr. FITZPATRICK also spoke, and Dr. NEVILLE did not reply.

MUMMIFICATION OF ONE FŒTUS IN A TWIN PREGNANCY; LABOUR AT TERM.

Dr. J. R. KIRKPATRICK exhibited a specimen of a mummified fœtus, with the placenta and membranes belonging to both children of a pregnancy which had gone to full time. There was a single placenta, and double membranous sac; that portion of the placenta which belonged to the mummified fœtus being shrunken and degenerated. The fœtus appeared to have died about the sixth month, and to have been since retained without occasioning any pathological symptoms. It was first born, after which the other child presenting by the

shoulder was turned and born alive and healthy. The living child, a female, weighed 8 lbs. The placenta was quickly afterwards naturally expelled. The mother was a healthy multipara, æt. 33; her six previous labours having terminated normally.

PATHOLOGICAL SECTION.—FRIDAY, JANUARY 6.

PROF. BENNETT (Sectional Secretary), and Mr. THOMSON (General Secretary), were in attendance.

SPECIMENS EXHIBITED BY CARD.

Dr. F. HEUSTON exhibited an oval, dermoid tumour of the right ovary, the circumference being ten inches, and the diameter nine. He had removed it from the body of a dissecting-room subject, æt. 65. The tumour was connected by adhesions with the surrounding viscera. Microscopic sections of the wall of cyst showed bony plates and nodules of cartilage. A fibroma existed in the upper and posterior portion of the vagina.

Mr. ARTHUR BENSON exhibited drawings of two cases of rupture of the choroid from external injury. Case 1.—From the left eye of a man, æt. 33, who received the injury three weeks before admission to the St. Mark's Ophthalmic Hospital by a fall from a horse. The rent in the choroid was seen to occupy a space midway between the disc and the yellow spot, and was crescentic in form, its concavity being directed towards the disc. The rent was marked by a considerable accumulation of pigment. The retinal vessels ran over it without any alteration in their curvature or direction. The pigment occurred six or seven weeks after the accident, and was not the remains of hæmorrhage. Case 2.—From a girl, æt. 19, who had, six months before admission, received a blow from a portion of an exploding coffee-pot. There were three separate rents in the choroid—one at the yellow spot; the second, a small crescent above the disc; and the third, a large irregular rent above the last, and near the periphery.

Mr. T. S. M'ARDLE exhibited tumours of the cerebellum, removed from a child, æt. 10, who, three days after a fall on his head, was admitted into St. Vincent's Hospital, with all the symptoms of cerebro-spinal meningitis. Sections of the tumour, prepared by Mr. P. S. Abraham, showed giant cells, with caseation of the central parts of the tubercular mass. Mr. M'Arde also exhibited a toe with fibroid tumour attached. The tumour was painless, and slow of growth, until within a month of its removal. A short time before admission into St. Vincent's Hospital, caustics had been applied, with the effect of increasing the size and altering the surface of the tumour, as well as rendering it painful. Mr. M'Arde likewise exhibited a specimen of thickening of nasal septum, removed from a patient who died of inflammation of the lungs, and in whom the nasal passages were almost occluded by thickening of the mucous membrane over the turbinated bones and septum.

Mr. ANTHONY H. CORLEY exhibited a specimen of extra-capsular fracture of the neck of the femur. The patient was over 80 years of age. It was not quite certain whether fracture was caused by a blow or a fall, as it was stated that she was struck with a poker, and fell in consequence. She lived three weeks after the accident, and had more power than usual in turning in bed. There were no signs of severe contusion. She suffered from bronchitis and emphysema, and died rather suddenly. The fracture was comminuted, the great trochanter being split vertically.

Dr. J. MAGEE FINNY exhibited a specimen of cirrhosis, or fibroid induration of the upper lobe of the right lung, in which the disease was strictly limited to that lobe, and had caused it to be converted into a series of cysts, varying in size from a pea to a small marble. There was a complete absence of the normal alveolar tissue, which was replaced by dense fibro-cellular tissue of a greyish red colour. The cysts, which, as a rule did not communicate with each other, contained a yellow muco-purulent secretion (free from special foetidity), and were lined with a mucous membrane, continuous with that of the bronchi. They permeated the entire lobe, giving it a very peculiar honeycomb appearance. The bronchi were slightly dilated in their tertiary division. It seemed as though the alveolar tissue alone, to the almost total exclusion of the pleura, and to the partial exclusion of the bronchi, was the seat of the fibroid change. No other

exactly similar case has been observed, and while the lines of demarcation between bronchiectasis and the cirrhosis of Corrigan are by no means so marked as some recent writers (including Tuergiersen in Vol. ix. "Ziemssen's Cyclop.") would imply, it was plain that in the specimen the bronchial dilatation had little, if anything, to say to the condition of the lobe. The pleura of the right lung was thickened, and adherent to a very slight degree, and sent no fibroid prolongations into the substance of the lung. The patient, a boy, *et.* 17, was under observation for but a week, having been admitted to Sir Patrick Dun's Hospital on Dec. 21st, 1882, for a supposed attack of pneumonia of the upper lobe. On the 26th Dec. physical examination showed the presence of what was thought to be a multiple abscess of that lobe, and pleural effusion of a latent type of the left side to the left of the sixth rib. In the course of the case, two days before death, the pleuritic friction was heard as high as the fourth rib. Over a limited extent, occupying the third and fourth costo-sternal articulations, a double friction sound, synchronous with the impulse of the heart, and increased by pressure, was readily made out, and heard by several observers. It was thought to be of pericardial origin, the inflammation being secondary to extension from the pleura. The post-mortem examination showed that there was no pericarditis, and that its real cause was the impact of the heart against the pleura, which was roughened and granular in its narrow prolongation under the sternum. Dr. Finny noticed the rarity and commented on the clinical significance of this physical sign. The cause of death was syncope, due to the sudden outpouring of fluid into the left pleura, and the incautious sitting up of the patient. On the evening before his death, the respiration was 28, pulse 120, temperature 102, and there were no signs of any asphyxia; the patient was resting easily on the *right* side, and expressed himself easier and better than he had been since admission, and during the day the fluid had not reached above the fifth rib in the semi-recumbent posture, and there were no symptoms suggesting, not to say demanding, mechanical relief. At three o'clock a.m. on the 29th he sat up to cough, as he was in the habit of doing on waking out of sleep, and whilst taking nourishment and conversing with the night nurse, he was noticed suddenly to become very pale and to be bathed in perspiration. He died in an hour. Effusion of a very rapid nature, and to a very considerable extent, must have occurred during that night, as the pleural cavity was found full of fibrino serum, and the lung compressed, without enlargement of the side or bulging of the intercostals. Trousseau and Bartel's notice of the possibility of sudden death in pleurisy, and their explanations of it as being by syncope, were detailed, Dr. Finny laying more stress upon the rapidity with which the effusion is poured out than on the amount.

Mr. SWANZY read a paper on

DOUBLE GLIOMA RETINÆ,
(Illustrated by a Living Specimen).

The patient was aged 2½ years. His mother first noticed a peculiar appearance in the interior of the right eye twelve months ago, and four months later in the left eye. At the first visit to the National Eye and Ear Infirmary six weeks ago, a growth was found in each eye of a pale yellow colour. In the right eye it lay deep on the posterior surface of the globe; in the left eye it came most to the front, occupying two-thirds of the vitreous humour, and presented a lobulated surface. The vitreous humour in each eye was clear. There had been no iritis or other inflammatory process, and there was no injection of the anterior parts of the eyeballs. There were not and had not been any head symptoms, and in all respects the patient's general health was perfect. He had never had any illness. The only changes since the case has been under observation are a slight increase in the size of the growths, and that the right eye has become glaucomatous. However, the child, who spoke remarkably well for his age, has lately spoken sometimes very indistinctly, and with much rapidity, and a forced repetition of the final letter of some words—thus: "bread-d-d-d-d."

Mr. SWANZY also read a paper on a

CASE OF INTRA-OCULAR TUMOUR.

(Illustrated by Microscopical Sections, prepared by Mr. P. S. Abraham.)

The growth had commenced six years ago, and when removed was, with the eyeball, the size of a hen's egg. It was still covered in front by conjunctiva and atrophied sclerotin, but had grown through the sclerotin above, and

displaced the eyeball downwards. The greater portion of the tumour was found to consist of a melanotic sarcoma, with round and spindle cells in the usual arrangement. Around the optic nerve, behind the globe, there was a considerable mass of tumour, containing less pigment, and in it there was an alveolar arrangement corresponding to Billroth's alveolar sarcoma. At one part of the highly pigmented portion, where it came in proximity to the conjunctiva, there were well-marked alveoli, containing epithelial cells, thus so far placing the tumour in the category of carcinomatous sarcomata described by Virchow.

The Section then adjourned.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

TUESDAY, JAN. 16.

Dr. GEO. BALFOUR, President, in the Chair.

Dr. ALEXANDER MILLER exhibited a little girl and boy with

GELATINOUS DEGENERATION OF THE KNEE-JOINT,

treated by Soot's dressing. It was first proposed to resect the joint of the girl, and amputate the leg of the boy; but Dr. Miller thought that he would give the above dressing a fair trial. Rest was, therefore, at first enjoined, and blue ointment applied next the joint; but this was soon discarded for vaseline, the strapping being then applied. The girl also suffered from strumous disease of the foot; but in both cases a useful joint had been secured.

Dr. BELL exhibited a man who, after a severe injury to his back, suffered from both

MOTOR AND SENSORY PARALYSIS.

He now possesses considerable motor power, but his gait is peculiar. He is able, however, to work for his living. He also retains the marks of considerable bed-sores. Sensation is almost entirely absent, except in certain areas of the legs; and he was unconscious when a horse stood on his foot, resulting in necrosis of the bones of the limb, the absence of sensation enabling him to pick out the portions of diseased bone without pain. The penis and scrotum can be pricked without causing pain. He is, however, married, and has several children.

Dr. P. H. MACLAREN exhibited a woman suffering from extensive

NECROSIS OF THE NASAL BONES.

Nearly all the bones of the nose had been removed. There was no history of contracted syphilis, as the woman was a virgin. She had been treated for scrofula; but Dr. MacLaren, suspecting hereditary syphilis, made inquiries, which confirmed his suspicion, and he, therefore, gave the iodide of potassium with most successful results, although the usual remedies for scrofula had failed to do any good. The case illustrates the late appearance of hereditary syphilis, no sign of the disease having shown itself for 17 years.

Dr. CADELL exhibited an infant with

A LARGE HAIRY MOLE ON THE RIGHT SIDE OF ITS FACE, due, the mother, as usual, thinks, to a fright from a dog during her pregnancy.

Mr. SYMINGTON exhibited a specimen which had come under his notice in his dissecting-room (at Minto House School of Medicine). It consisted in the presence of

A CERVICAL RIB SPRINGING FROM THE SEVENTH CERVICAL VERTEBRA,

over which the subclavian artery passed, and might have given rise to the idea of an aneurism. He also exhibited a student who, according to Dr. Bell, possessed a like abnormality.

Dr. JOSEPH BELL then read a most interesting paper on A PECULIAR MENTAL STATE AS THE RESULT OF CRANIAL INJURIES.

Dr. Bell drew attention to the case of a patient under his care who had received severe injuries to his head in falling down a well. The man could recollect nothing connected with the well, or the cause of his fall, nor could he, for some time, recognise his wife or friends. He has since recovered, but the incident of the well has entirely vanished from his mind. Dr. Bell instanced several cases where entire absence of all recollection of the immediate occurrences of an accident had been lost. In this case, the man recognised

persons he had known twelve years ago, but could not recognise his wife, to whom he had been married for that period. To explain these phenomena, Dr. Bell, after referring to some remarks lately made by Mr. Savory on brain injuries, suggested that time was required for the registration of ideas, and that in these cases so rapid was the sequence of events that the brain failed to register them.

This suggestion brought forth some valuable remarks from Dr. Clouston, of Morningside Asylum, who agreed with Dr. Bell; and from Dr. Calderwood, Professor of Moral Philosophy in the University, who propounded some metaphysical doctrines in explanation, but who admitted that he could only explain Dr. Bell's cases on the physical basis of mind. Dr. Gunning also made some remarks, and

Dr. BELL, in reply, stated that he never knew of a case of concussion where there was not considerable damage found in the brain after death, and he was sure that many of the cases of contradictory statements made in the witness-box after railway accidents were to be attributed to no registration of the occurrence by the brain, and that the sufferers in all good faith drew on their imaginations to supply the want.

Dr. P. H. MACLAREN then read a paper on

A CASE OF STRANGULATED HERNIA.

The Society then adjourned.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.
MONTHLY MEETING, JANUARY 5TH, 1883.

Mr. FREDERICK LAWBRANCE in the Chair.

COLLOID CANCER IN THE PERITONEUM—POST-HEMIPLEGIC
HEMICHOREA—RECURRENT FIBROID—CALCULUS IN THE
URETER.

Dr. THOROWOOD exhibited a patient admitted under his care into the West London Hospital on December 13, 1882, whom he believed yet to be suffering from malignant disease of the abdomen. On examination the abdomen was much distended. Slight evidence of localised fluctuation could be detected in the flanks, and the patient said that when in St. Mary's Hospital last August he was tapped by order of Dr. Handfield Jones in the left flank, from which serous fluid was drawn. He is now losing flesh, has a quiet pulse, clean tongue, does not vomit, heart and lungs act normally. On feeling the abdomen a hard, very tender mass is found below ensiform cartilage, about 2 in. by 2 in. in size; doubtful, if this mass moves much in respiration. Below this comes a zone of resonance, then across abdomen can be traced, at level of umbilicus, a chain of hard, tender, irregular masses. Liver dulness somewhat increased upwards.

History of the patient, and mode of the development of the disease.—Twenty years ago he came home from India invalided for dysentery, and ten years ago he had slight coughing up of blood. With these exceptions his health has been good, and he has been able to walk four or five miles easily until quite recently. Present illness commenced with enlargement of abdomen five weeks before his admission into St. Mary's Hospital on August 21st, 1882. The liver did not then extend below margin of the ribs. *Paracentesis abdominalis* was performed, and after that liver dulness extended eight fingers' breadth upwards in right chest. No lumps were felt in the abdomen at this time, but a hard mass was felt and recorded below the xiphoid cartilage, which was believed to be the left lobe of the liver. The urine contained lithates, but no albumen. The case was set down as cirrhosis with ascites, and on November 2nd the patient left St. Mary's. He says that, while in that hospital he had a dose given him which brought away three yards of tapeworm, but not the head of the parasite. Before tapping, his abdomen measured 38½ inches at level of umbilicus. Present measurement 34 inches. The question of interest is—What is the nature of the disease? When he left St. Mary's, Dr. Handfield Jones wrote the exhibitor that he considered absence of pain and presence of ascites was against cancer and in favour of cirrhosis. But he added "he may have both maladies." My own belief, added Dr. Thorowood, from the first, has been that the disease is colloid cancer. The age of the patient favours such a belief. In a case of colloid cancer reported by Dr. Ord (*Path. Trans. xxxii.*), the patient had been ailing seventeen years, and at the age of 35 his abdomen measured 44

inches, while two "bun"-like prominences were felt on each side of umbilicus. Tapping in various parts of abdomen brought away quantities of fluid varying from a-half to three pints. Post-mortem showed the parietal peritoneum covered with colloid growth to the extent of from two to four inches, the omentum a dense honeycomb-like mass of colloid cancer; liver and stomach encased, but not infiltrated by colloid. Curling reports a case where colloidal cancer caused a stricture of the colon; so that colotomy had to be performed (*Path. Trans. xvii.*). I cannot venture to say whether enlargement of the mesenteric glands, set going by the Indian dysentery contracted twenty years ago, and from which the patient seemed to recover during his residence in England, can have much to do with the development of the abdominal tumours; neither do I agree with the patient in attributing these appearances to the retained head of the tapeworm. We are informed on the best authority that no lumps were found in the man's abdomen when he was in St. Mary's three months ago. Of the existence of the masses now, anyone present can easily convince himself; so that they have grown and are growing rapidly after the manner of colloid cancer. The part invaded, apparently the peritoneum and omentum, is a part especially affected by colloidal cancers. We have seen from Dr. Ord's case, how collections of fluid may form in various parts of the abdomen in common with colloid, and thus it appears to be with the patient, for his flanks are to some extent resonant, and yet, by a little manipulation, we get sense of fluctuation at certain points. At present, the functions of the stomach and intestines are not much affected, but he loses flesh rapidly, and the prognosis is, in my opinion, anything but favourable. In treatment we have endeavoured, by means of saline purgatives, to relieve congestion and oppression, and at night we give him extract of conium to relieve pain.

Dr. SCHACHT said that they had lately, in the obstetric department of that hospital, a case where a mass could be felt on deep palpation in the epigastric region, which was diagnosed as malignant, and proved, at post-mortem, a mass of encephaloid cancer.

Dr. ALDERSON remarked that cirrhosis of the liver was excluded from the diagnosis by the absence of contraction.

Mr. LLOYD said that he had made a post-mortem in the case of a young woman who had cancer of the ovaries, and where the omentum was much diseased.

Dr. THUDICHUM asked for a definition of "colloid cancer." He knew what "colloid" meant, and he knew what "cancer" meant, but he did not understand the combination of terms. As the case under notice was of long standing, it was very interesting and important, but he was not clear as to the possibility of diagnosing abdominal cancer in the living human being. Then, as to treatment, he could not understand why extract of conium was administered, as so little was known of its influence. He questioned whether it contained any alkaloid; and, indeed, whether it had any medical effect whatever. It was not chemically definable. He felt curious as to its effect in the remarkable case under notice.

Dr. POPE said that he knew a case of an old man who had large masses in the abdomen, swelling in both sides, and much obstruction in breathing. There was also localised fluid easily felt in the flank. It turned out to be sarcoma, originating in stone and chronic kidney disorders.

Dr. DANIEL, referring to the disputed use of extract of conium, said that he preferred morphia as a sedative, because it was more certain in its operation.

Dr. ALLDEN OWLES did not regard the comparative absence of pain as weighing much against the symptoms of cancer in the case, as, in his experience, severe pain was far from being an invariable concomitant of abdominal cancer.

Dr. THOROWOOD, in reply, said that it was, of course, possible to have abdominal cancer without pain. This might be a case of sarcoma, but the locality indicated that it was a colloidal form of cancer. He regarded extract of conium as a useful sedative, and absorbent, although it was not clear what was its effective principle, and although its mode of action was obscure.

Mr. PERCY POTTER showed a case of

POST-HEMIPLEGIC HEMICHOREA WITH HEMIANÆSTHESIA, in which there were some peculiar clinical features. The patient, æt. 32, has been a soldier, has always enjoyed good health previously to the present affection. He never had

rheumatic fever nor syphilis, nor was there history of injury to the head. The family history was good, except that mother had temporary chorea. Eighteen months ago, whilst playing a wind instrument under the tropical sun of India, he became suddenly unconscious. The patient cannot say how long this lasted, but when he came round there was right hemiplegia without aphasia. This improved to some extent, but the muscles of the legs became atrophied, and the flexors of the foot tonically contracted, assuming, as in paralytic club-foot, the form of talipes equina. Having returned to England, he was operated upon for this contraction, tenotomy of the tendo-achilles being performed at Netley Hospital, three months after the outset of hemiplegia. This does not influence the deformity. Three weeks ago the patient was frightened by a mastiff dog which knocked him down. Two days after there appeared chorea of the affected side. There was now well-marked right hemiplegia, including the face, without aphasia; the vision of the right eye was defective; the senses of smell, hearing, taste (as tested by aloe and colocynth), were blunted. There was complete anaesthesia of the right side of face and leg; less complete of arm, trunk, and thigh. The symptoms of chorea consisted of sudden and unexpected jerks of the right arm and thigh, and right side of face. The muscular movements were quite uncontrollable. Tendo-reflex and ankle clonus increased. No cardiac bruit; urine normal. Prof. Charcot describes three cases of this disease, all occurring in the female sex. He found that the lesions in the encephalon were in similar situations, viz.:—(a) Posterior part of optic thalamus, (b) posterior portion of the nucleus caudatus, (c) back portion of the corona radiata, these lesions consisting of cicatrices, probably hæmorrhagic. Apoplexy was very rare in many so young, but there was very little doubt as to the apoplectic nature of these phenomena.

Dr. Schacht made some remarks on the disease, and Dr. Thudichum thanked Mr. Potter for exhibiting this interesting case. In reply to these, and inquiries by Drs. James Thompson, J. Frankish, Ralph Richardson, B. Daniel, Pope, and Bennett, Mr. POTTER said there was no doubt that apoplexy was caused by exposure to a hot sun. The chorea was unquestionably due to fright. It was difficult to ascertain if there was reflex action as the moment he attempted to touch the limb the man winced. On one occasion, however, when the man's attention was diverted he observed that the tendon reflex was exaggerated. He had not been able to observe the patient during sleep.

Dr. JAMES THOMPSON showed a tumour removed from a woman, æt. 36, after its fifth recurrence. Its situation was in the median line at the border of the hair in the forehead. The size was that of a goose's egg, springing from a base only three-quarters of an inch in diameter. The original tumour was removed in 1869. At least four surgeons had operated. Both caustics and the knife had been used. Dr. Thompson operated with Richardson's scissors, and applied an actual cautery to the root. A committee was appointed to report upon the character of the tumour. Dr. Thompson also exhibited a calculus believed to have been formed in the ureter, and read the following notes:—W. D., æt. 45, market dealer, plethoric, free liver, suffered for years from lithiasis, and passed several small stones, applied, while suffering from severe pain in left loin and down thigh; the diagnosis was a stone passing through ureter. After some time he obtained sudden relief. A few hours after two stones were passed with the urine, one with a face on one end, the other with a face on each end, about one-sixteenth of an inch long, and cylindrical. Two days after a third was passed about three-quarters of an inch long, of the same shape, and with a face at each end which fitted that already passed. Two months after the patient had a similar attack which terminated fatally in two days with symptoms of acute peritonitis, possibly caused by a similar condition of the other ureter. No post-mortem was obtained.

Our "advertisement columns" contain the list of subscribers to the Appeal in Dublin on behalf of the widow of the late Dr. Spencer, F.R.C.S.I., and Mrs. Spencer's acknowledgment of the receipt of the amount collected.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 24, 1883.

THE HOUNSLOW TRAGEDY.

THE circumstances under which Dr. William Whitfield Edwardes committed suicide at Hounslow having been for more than three weeks under investigation before Dr. Diplock, Coroner for West Middlesex, the jury have at length decided, "That on December 27th the said William Whitfield Edwardes came to his death by prussic acid administered by his own hand during temporary insanity; and they desire to express their opinion emphatically that he was driven to his death by the pressure brought to bear by his partner, Dr. William Michael Whitmarsh, using the false charge of Mrs. Rose Bignell as a means to drive him to a dishonourable dissolution of partnership."

The facts of the case are probably familiar by this time to every member of the profession, none of whom can help but feel deep sympathy for the friends of the unhappy suicide, or fail to experience a sense of keen regret that so damning a verdict as that quoted above should have been necessary to express the opinion of a British jury respecting the conduct of a practitioner of medicine. This, after all, is now the most unfortunate feature of the whole affair, and much as we must naturally regret the existence of reasons that force so unpalatable a conclusion, it is impossible to regard the verdict as in any degree undeserved or hypercritical. Throughout the transactions which followed the first delivery of the charge brought against the late Dr. Edwardes by the woman Bignell, the attitude of Dr.

Whitmarsh towards his partner was, judging from the evidence of himself and his assistant, the man Garrett, entirely deficient in such cordial sympathy and helpful encouragement as it was his imperative duty to offer until, at least, some substantiation of the patient's accusation was forthcoming. Instead of this we find that Dr. Whitmarsh apparently seized the opportunity afforded him by the difficulties of his *confrère* to insist on a dissolution of the partnership existing between them on terms which a jury of Englishmen have deservedly stigmatised as "dishonourable." Had the offence alleged against Dr. Edwardes been already proved, Dr. Whitmarsh could hardly have shown more eagerness in hurrying forward measures for effecting a severance in his connection with him; and, looking back upon the picture of the relations between the partners, as drawn out in the evidence before the coroner, we cannot refrain from an emphatic endorsement of the verdict to which that evidence contributed, or from a further expression of opinion that, had the deceased practitioner received such assistance as may be claimed by even the most guilty prior to conviction, he would never have contemplated the dread alternative to ruin forced on his acceptance by despair.

The whole history of the case excites our deep compassion, the more so because it is in many things so typical of the many dangers surrounding medical men under certain conditions. There are few practitioners of experience who have not been momentarily exposed to the risks of some such charge as that levelled at Dr. Edwardes; and every physician starting on his daily round of visits is conscious of the fact that he may return to his home with a charge of indecency brought by a hysterical patient hanging over him and calling for immediate action from himself. Nor can we ever expect that dangers such as this will be less frequently encountered so long as the hysterical temperament is recognised as a feature calling for medical aid to women. These latter, when influenced by hysteria, unconsciously exaggerate the meaning and importance of the most trivial actions and attentions; they attribute the most impossible motives to their attendants; and with a morbid acuteness of appreciation of self, they associate even ordinary acts of courtesy and of professional necessity with a force of meaning towards themselves which is characteristically egotistical in the extreme. Fortunately it is but rarely that the extreme length to which Mrs. Bignell's higher sensitiveness impelled her to proceed commends itself to the hysterical; but when false charges of the kind are framed, it is easy to see the successive steps of their formation. We need not now point these out at length, for they are sufficiently familiar to be at once recalled by every reader of these pages; but in judging for himself of the merits of the case just recently closed, each should remember how all but impossible it is for a woman of hysterical temperament to forego any idea once aroused in connection with herself, and by nursing which she can consistently exalt her individual importance.

Ungrateful though the task has been, we have not been able to avoid condemnatory utterances in dealing with Dr. Whitmarsh's relations to Dr. Edwardes. It is

at all times painful to us to reflect unkindly on the speech or conduct of members of the profession; but, nevertheless, the highest duty we owe to medicine as a conservator of its interests is to speak out at all times fearlessly in its behalf. And this demands that we should declare the regret with which we have witnessed Dr. Whitmarsh's readiness to turn an accusation against his partner into an occasion for his own advantage. Strong terms might well be excused in dwelling on a transaction so utterly divorced from the glorious traditions of fraternity which rule most of the relations existing among medical men; but in the social ruin which has overwhelmed Dr. Whitmarsh as the direct consequence of his own performances we may fittingly bury the indignation aroused by his unbrotherly and—we say it in the strictest sense—unprofessional conduct.

Against the woman who was the miserable cause of Dr. Edwardes' untimely death it would be purposeless to declaim. She, too, loses immeasurably more than she could possibly have gained as the consequence of her trumped-up charge; but she will be an unintentional agent for good if one result of the calamity she has initiated shall be to arouse in the minds of medical men the necessity for increased caution in dealing with women who may possibly be hysterically inclined.

To the family of the unfortunate victim of circumstances, to those who are left to lament the loss of husband, father, son, we would tender our deep-felt, earnest sympathy. Though in a moment of weakness his hand, now still for ever, was raised against himself, yet in the act of self-destruction can we not discern the evidence of a sacred feeling of despair engendered less for himself than on behalf of near and dearly-loved ones? With the whole history of the case before us, it is easy to imagine that this dread way out of the difficulties surrounding him seemed to offer better chances of honourable exposure in the interests of his family than would be secured in the event of public notice being attracted to himself as the accused medical attendant of a young woman. Fortunately, however, there is far from any need to urge *de mortuis nil nisi bonum* as far as Dr. Edwardes is concerned; while alive he was esteemed for the honour and integrity of his disposition; and now, though dead, his character is without a stain—his memory is held in affectionate regard.

THE CASE STATED AGAINST THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES BY THE ATTENDING PHYSICIAN.—No. VI.

OUR criticism upon the proposal to compel the physician to notify all cases of infectious disease to the sanitary authority has been hitherto devoted to proving that the proposed law is without precedent, unconstitutional, dangerous to the public health, partial in its application, and unworkable. The advocates of the proposed law have at no time attempted to meet these indictments by denial or explanation; they have admitted that the proposed Act has no analogue amongst the laws of England, but they consider that the sooner a precedent is made for coercion

of the medical profession, the better ; they agree that it is unconstitutional to make a guiltless practitioner responsible for the fault, mistake, or misfortune of his patient ; but they say that it is convenient to do so, and therefore justifiable ; they admit that, where the law they advocate is in operation, it is one-sided in its application and incapable of being uniformly enforced, but they assert that, with all these faults, the law is useful, and that—whether it is bad or good in principle, or even oppressive on individuals—it ought to be enacted.

It is indeed the sole argument of the compulsionists that compulsory notification by the physician, whatever its faults may be in principle and theory, has been found, in practice, to be effective and convenient, and ought, therefore, to be the universal law ; they appeal to experience against every objection which is raised. Let us see what answer experience affords, and let us satisfy ourselves whether there is, indeed, any conclusive proof that compulsory notification by the physician has produced, in the communities in which it has had a full trial, any benefits commensurate with the personal annoyance and public expenditure which it has involved. It is emphatically our contention that, speaking generally, no such benefits have resulted ; that the data upon which medical officers of health argue out the case for compulsion are altogether unreliable, and prove nothing ; that the true tests for an improvement in the public health of notification towns have been ignored, or purposely kept out of sight. We boldly assert that, as a matter of fact, zymotic mortality has been rather increased than diminished, and the danger of infection rather been aggravated than mitigated by the introduction of the law of compulsory notification by the physician, and that it is so aggravated because of the habitual exclusion of the physician from the early treatment of the disease, and the consequent wholesale concealment and secret dissemination of the infection.

We are justified in asking the advocates of compulsion why it is that there should be any doubt on this point, and why it is that they are unable to prove the efficacy of their great sanitary panacea by incontrovertible statistics ? They have had the uncontrolled use of notification compulsion for six years in Bolton and Greenock ; for five years in Burton, Jarrow, and Nottingham ; for four years in Blackburn, Blackpool, Derby, Leicester, Llandudno, Norwich, Rotherham, Warrington, and Edinburgh ; and for shorter periods in eleven other English towns ; and they surely ought to be able to point to the vital statistics of these towns as unquestionable evidence of the benefits of physician-notification, if such benefits be demonstrable. We assert that the compulsionist party, speaking through the mouths of the Medical Officers of Health of these towns, have utterly failed to adduce any such proof.

The history of the notification agitation is as follows :—Many years ago a number of earnest sanitarians, seeing the danger to the public health from the uncontrolled dissemination of disease, set on foot an agitation having for its object to cause early intimation of infective cases to be recorded, in order that immediate steps might be taken to prevent the spread of infection from the individual to the public. It does not appear that in the inception of this praiseworthy movement any one thought of making the attending physician the culprit ;

but after a time the sanitarian party—whose zeal exceeded their discretion, and who did not take time to consider the effect of forcing the physician into the service—conceived the idea that the doctor would be the handiest agent for their purpose, and they hastily proposed that he should be compelled to act. Straightway the Medical Officers of Health of certain towns, seeing clearly that this arrangement would save them and their departments much of the trouble and expense of ferreting out infective disease and punishing the disseminators thereof, grasped eagerly at the suggestion to make the physician liable ; but they did not venture to ask honestly and openly for Parliamentary authority to put the medical profession under the yoke, on the contrary, they watched their opportunity, and when the first occasion arose of a private gas, or water, or police, or improvement Bill for the township, they smuggled into it the needful clauses to compel the physician to notify infective disease. We shall not now dwell upon this method of evading the vigilance of the House of Commons and of the medical profession. Suffice it to say that so many medical officers of health, finding the trick easily done, and the new system a considerable saving of labour for themselves, began to introduce compulsory notification clauses into their private local Bills that the Home Secretary took alarm in the last session of Parliament, and stopped the whole of the Bills, no less than eight in number, until inquiry could be made by a Special Committee, which he appointed for the purpose of "reporting on any provisions in private Bills promoted by municipal and other local authorities by which it is proposed to create powers relating to public or sanitary regulations which deviate from, or are in extension of, or repugnant to, the general law." We shall refer to the constitution of this committee, and the conclusions at which it arrived, on another occasion.

At the suggestion of that committee, the English Local Government Board obtained from the Medical Officers of Health of all notification towns—a series of reports which were subsequently printed as a Parliamentary paper (N^o. 164, House of Commons, April 27, 1882). These reports are the only available source of information to us. On them the whole case of the advocates of physician-notification is based, and we assert that they omit carefully the proofs which, in favour of compulsory notification, might carry conviction to the public mind, and contain nothing whatever to satisfy us that it is desirable to make general the law which has heretofore been local. The questions put by the Local Government Board were addressed to the Town Clerks of notification towns, and to no one else ; the medical practitioners in those towns, who know more probably of the actual working of the Acts than the corporate officials, were not asked a question ; nor was it known to them that the Committee was about to sit, or that inquiries were being made in which they were, both professionally and personally, deeply interested. With sanitarian and corporate opinions and interests the Committee was glutted, but of the actual working of the notification system in detail, of the experience obtained by the medical profession in its daily intercourse with the public, and of the sentiments of the public itself, the Committee was absolutely uninformed. Its decisions were, therefore, absolutely valueless as a judicial pro-

nouncement, being founded upon evidence given *ex parte*, without an opportunity being afforded to any one to controvert the statements made.

The questions put to the Town Clerks by the Local Government Board would also seem to have been carefully worded, for the purpose of leading the Medical Officer of Health to give a reply favourable to compulsory notification, and to conceal all facts which might throw doubt on the efficacy of that system.

They were as follows:—

a. Are the local authorities satisfied with the working of compulsory notification?

b. Have they any suggestions to make on the subject?

c. Was public attention specially directed to the intention of the local authority to apply for the (notification) powers?

It will be observed that if the Local Government had desired to put a false issue before the committee, it could not have done so more effectually than by these inquiries. If it were seeking to ascertain whether compulsory notification had been found to work beneficially for the public health, it might have put interrogatories which would have elicited something much more valuable in the way of evidence than the "satisfaction" of the local authorities.

Of course the local authorities are satisfied. Why should they not be, considering that compulsory notification by the physician supplies them with an unpaid corps of sanitary detectives, who, if they do not work to their satisfaction, may be fined and imprisoned? Of course the Medical Officer of Health is well "satisfied," considering that almost all the trouble of detecting infection; of following it up to its sources and punishing its disseminators is taken off his hand by the forced labour of the local medical practitioners, and he is thus relieved of a most onerous duty.

(To be continued.)

Notes on Current Topics.

Electricity v. Hangings.

A MEDICAL contemporary has paid us the unusual compliment of reproducing, under the above heading, the article on "Sudden Death" which appeared in our columns a fortnight ago, interspersed with a few critical remarks, to avoid, we presume, the necessity for inverted commas. Our contemporary is afraid that our prediction that murder will one of these days be committed by means of electricity may catch the eye of some would-be murderer and induce him to invest in a battery forthwith, and it chides us for making public so dangerous a suggestion. But the true way to meet a danger is not to cover it up and make a mystery of it, but to expose it as much as possible, and our hint as to murder by electricity will certainly do more to prevent than to promote that new development of homicidal ingenuity. Our contemporary is much exercised because we have used the expression "death by the visitation of God," which it thinks should have been "death from natural causes." It ought to be aware that that expression is constantly employed by coroners' juries in cases where sudden death has taken

place, but where no natural causes of death are clearly established, while at the same time there is no reason to suspect the intervention of man; just in those circumstances, in fact, which would exist in a case of murder by electricity. Where natural causes are alleged, natural causes have been proved to have been in operation to the satisfaction of a jury, but our point was that in death by electricity, the body when found would afford no evidence as to the manner in which death had occurred. Our contemporary doubts whether death by electricity is painless, but Dr. B. W. Richardson's experiments have shown that there is a time element in pain, and the instantaneous manner in which animals killed by Mr. Lane Fox's apparatus drop dead, without a subsequent movement or quiver, precludes the idea of pain in the ordinary acceptance of the term. A letter in the *Daily News* on the 18th inst. again advanced many of the arguments adduced in our article on "Sudden Death."

Ophthalmology and Otology in the University of London.

AT the last meeting of Convocation, the following resolution was brought before the house, being moved by Dr. J. Meek, and seconded by Dr. Horrocks: "That, in the opinion of Convocation, it is desirable that a clinical examination in diseases of the eye and ear (to be conducted in each case by special examiners) should be added to the subjects of the M.B. examination." The further discussion was opened by Dr. Hilton Fagge, but for want of a legal quorum was adjourned.

Remarkable Monstrosity.

DR. M'DONNELL, of Sheffield, was called last week to a case—a birth—reported in the local papers in the following terms:—The infant was without arms or legs; but hands protruded from each shoulder, though there were only three fingers to each hand, and no thumbs. The feet were perfect, but they were simply attached to the lower portion of the body. The right eye was a little above where the eyebrow should be, and the left eye was at the side of the head, situated on what medical gentlemen call the parietal bone. The mother is sixteen years old, and the reputed father not quite eighteen. Both are apprentices in the Sheffield trades. Dr. M'Donnell says that the mother would not admit she was pregnant, and probably laced very tightly to conceal her condition.

THE death-rate last week from diseases of the zymotic class was again exceptionally low throughout the United Kingdom, not one being referred to these causes in Brighton, Norwich, Wolverhampton, Derby, or Blackburn. The highest annual death-rates per 1,000 in the large towns were—From whooping-cough 2.3 in Leeds and in Cardiff, and 3.7 in Preston; from scarlet fever 1.6 in Leeds and 1.7 in Sunderland; from measles, 1.2 in Cardiff; and from "fever," 1.0 in Newcastle-upon-Tyne, and 1.2 in Liverpool. The 26 deaths from diphtheria included 14 in London and 8 in Glasgow. Small-pox caused 7 deaths in London, but not one in any of the large provincial towns.

Porro's Operation.

SINCE Dr. Clement Godson performed Porro's operation successfully in November last the proceeding has been resorted to on two occasions by other operators, but in neither of these cases has it resulted favourably. Dr. Godson's case consequently remains the only one in Great Britain in which the life of the mother as well as that of the child has been preserved by a resort to Porro's operation. It is most satisfactory to learn that the former continues to progress in every way favourably, and that she has just recently left for a month's residence in a convalescent home, being able to walk without ache or pain, and feeling, as she expresses it, "better than she has ever done in her life." It is right to add that Dr. Godson attributes a very considerable part of his patient's recovery to the good feeding and careful nursing provided for her, and, indeed, since the date of the operation she has steadily advanced towards complete convalescence. This good result, though it may not be held to justify resort to the operation in cases formerly regarded as not admitting its adoption, must, notwithstanding, encourage the anticipation of hopeful issues under circumstances which absolutely call for it or an equivalent attempt to save two threatened lives; and in this direction the influence exercised by Dr. Godson's successful case will be most helpful and grateful.

Surgery of the Intestines.

IN an address in surgery, by Dr. W. A. Byrd, and reprinted from the Transactions of the American Medical Association, the author enters on an interesting review of the progress in surgical procedures in connection with excisions of portions of the alimentary canal covered by peritoneum. From a study of the results obtained in this branch of practice by others and by himself, Dr. Byrd is led to formulate the following conclusions:—

1. Any portion of the alimentary canal may be safely excised, and stricture, cancer, perforating ulcer, gangrene, and some gunshot wounds demand that it should be done.
2. The method heretofore adopted of suturing the divided ends of the bowel is dangerous, because tympanites, by pressing upon the heart and lungs, interfere with the vital processes in a patient already worn down by disease and shock, and, by distension, causes traction upon the sutures in such degree as, in many instances, to cause their giving way, which is followed by fecal extravasation, peritonitis, and death.
3. These dangers are to a great extent obviated by making an artificial anus, thus permitting the escape of gases as they form.
4. Artificial anus is easily cured by a plastic operation specially devised by the author.
5. If that portion of the bowel which constitutes the epéron be cut away (being careful not to cut away the mesenteric attachments) at the time of the first operation no future operation will be found necessary, as the artificial anus will close spontaneously by cicatricial contraction.

At the recent preliminary examination of the Irish College of Surgeons, 52 candidates presented themselves: 16, or 30 per cent., were rejected; of the remaining 36, 12 obtained first class certificates, 14 second class, and 10 third class.

General Medical Council.

THE Executive Committee of the General Medical Council assembled on Friday, January 12th last, when official notification was received of the re-appointment of Dr. Fergus as Crown nominee for Ireland from November 30, 1882, and of Dr. Pyle as representative of Durham University from December 12, 1882, the term in each case being for five years. The Committee had before it also the pleasing duty of endorsing the additional income derived from the operation of that ingenious arrangement which mulcts a practitioner of five shillings each time he omits to inform the Registrar of the Council that he has lived twelve months since last communicating with that official. Numerous names, it appears, have been erased from the Register under the 14th section of the Medical Act, and a fee of five shillings was received in each case for restoration. In reply to a request from the Medical Faculty of the University of Malta, requesting recognition of its degree as admitting its holders to the Register, it was resolved "That the General Medical Council has not power, as the law at present stands, to do as requested, or, indeed, to recognise the degrees of any foreign or colonial University as a qualification for registration in the General Medical Register of the United Kingdom constituted by the Medical Act of 1858; but that possibly the law on this subject may before long be altered, when the claims of the University of Malta will doubtless receive due consideration at the hands of the General Medical Council." We may be permitted earnestly to hope that the University of Malta will not be unduly excited at the prospects thus offered up before it, and that the possibility of being "duly considered" by that august assembly, the General Medical Council, will compensate for the temporary discouragement it has just now to submit to. In addition to formal work, the Committee munificently returned the extravagant sum of £4 19s. 6d. to the Liverpool Medical Defence Association, being the amount of a fine inflicted on an unqualified quack at the suit of the Association. This act of charity, however, should not lead to the belief that the Council is in any way awaking to the duties it should perform. It is rather a sign of increasing weakness, since it has generally shown greater readiness at receiving money than at giving it away in furtherance of medical reform.

The Irish Academy of Medicine.

ON Friday evening there was a very largely attended meeting of the Medical Section at the King and Queen's College of Physicians. Dr. R. Hayes read an interesting paper on empyema, and was followed by Professor Purser, who described two cases of the same disease, in one of which the purulent effusion had displaced the liver downwards, and the heart was against the left axilla, leaving almost no lung-room, and with but little distress. In this position there was a remarkable bruit owing to the twist of the aorta, and during tapping the heart could be heard returning to its place, and the bruit disappeared. He mentioned that in drainage he employed a long syphon tube of india-rubber dipping into a bottle, and that germs did not enter by that tube. He also read some interesting points upon aseptic fever. Dr. A. H. Benson

exhibited a living specimen of hard chancre on the inside of the upper eyelid; and Dr. Finny a curious case of skin disease. Several specimens were exhibited by card. Dr. A. W. Foot showed several coloured drawings of facial chromidrosis, a department to which he has devoted great attention, and has written several papers. Dr. H. Kennedy presented a urinary calculus. It is evident that the Colleges are not too intolerant with regard to surgery. Dr. C. Nixon showed a very interesting case of aneurism of arch of aorta obliterating the arteria innominata. Dr. F. J. B. Quinlan exhibited, under the microscope, two specimens of tubercular bacillus. One of them was the sputum of a phthisical patient, and in it the bacilli were stained with magenta aniline, and the elements of the sputum with methyl blue. The other was the section of a phthisical lung, and in it the bacilli were coloured with fuchsine and the lung tissue with brown chrysoidine. This meeting was altogether a very successful and interesting one.

An Aseptic Chamber.

HERR A. SCHÜCKING, of Pyrmont, has constructed an aseptic chamber, for employment during treatment of grave surgical cases, and for perfect isolation in cases of infectious disease. It is in reality a double chamber, each compartment of which is air-tight. It is rendered aseptic by filtration of all air entering through layers of cotton. The current is created by an exhaust pump driven by a half horse-power hot-air engine, capable of extracting 30 cubic metres of air per minute. The walls of the chamber can be kept clean by washing with solution of carbolic acid. The patient's clothing is to be of linen, and over this a waterproof covering, both to be disinfected before employment. In the second, or antechamber, is a bath for disinfecting purposes. The arrangement seems ingenious and complete as far as it goes; all that is now wanting is to disinfect *the intestinal canal and its contents*, as, as is well known, microbes easily find their way from the digestive tube into almost any part of the body.

"Unification."

THE Army Medical and Transport Inquiry Committee at the War Office is now believed to be approaching the end of its labours. The medical branch of that inquiry is about concluded, and the report of the Committee will be drawn up without delay, so that such changes as may be adopted on its recommendation in regard to the Medical Department shall appear in the forthcoming estimates. Men interested in those changes naturally enough ask what are they likely to be? Probably, up to the present time, the Committee itself has not arrived at a decision on this matter; at all events, nothing very precise has oozed out regarding it, but men who think they can put this and that together believe that the recent order issued, calling for volunteers for the Army Hospital Corps, is to be taken as a forecast of what the recommendation is to be on that particular point. It appears that some at least of the medical officers who served in Egypt have undergone a very strict and exhaustive examination by that Committee; and this being so, they have doubtless spoken out their minds on the several points with which they were personally cognisant. Whether medical, and still more especially

military, officers from large camps and garrisons at home have been examined as to their experience of the working of the "unification" so-called "system," does not yet appear. It is to be hoped that if they have not yet been so, this omission may be corrected before the Committee closes its inquiries. Perhaps those officers, or rather such of them as are married, could give some unexpected information as to the actual money loss this "system" causes them yearly, through fees paid to private practitioners, rather than have as professional advisers to the several members of their families the medical officers officially appointed for this very purpose. Medical officers might also be examined as to how far, under the present "system," they have lost touch of their military brethren as compared with former days, when all alike were members of the same regiment, and equally tied by the sentiment of *camaraderie*.

Cholera.

RECENT accounts from India state that cholera mortality in Calcutta is increasing; the disease is mostly confined to the northern part of that city, and prevailing with greatest severity in the suburbs. Thus it appears that the seasonal outbreak of this disease occurs earlier on the present occasion than has usually been the case in past years, and it will be interesting to learn by-and-by whether the appearance of the epidemic was or was not attended or preceded by any unusual meteorological conditions, and if so, of what nature. In the midst of a chaos of uncertainty with regard to the ultimate causes upon which cholera depends, continuous experience in India is teaching us that, at any rate, the theory of filth in air, water, or earth is of itself insufficient to account for the disease. In Calcutta, for example, what between works of conservancy and works of water supply, the place has been sanitated to a degree bordering on the unbearable—financially—and yet cholera has actually the face, as if in derision, to make its appearance two months earlier than in "the good old times" of dirt.

The Lismore Union Case.

It will be recollected that the Irish Local Government Board recently suggested to the Lismore guardians to dismiss a medical officer whom the Local Government Board had itself declared merited no such treatment. The officer who was thus the victim of the spite of his guardians and the feebleness and tergiversation of the Local Government Board was got rid of really because he was not popular with the Duke of Devonshire's agent at Lismore—ostensibly because he could not get on harmoniously with a fever hospital nurse and master of the workhouse, who were *protégés* of the said agent. Whether the medical officer had or had not cause for reporting these officers in the discharge of his duty may be judged from the following excerpt, which we cut from the local paper:—

At the usual weekly meeting of the guardians, F. E. Currey, J.P. (agent to the Duke of Devonshire), presiding, a letter was read from the fever hospital nurse stating that she wished to make a statement to the board.

The nurse was admitted to the board-room, and stated to the guardians that the porter used expressions im-

putting that parcels containing union property had been conveyed out of the workhouse by members of her (the nurse's) family.

The porter was called before the board, and admitted that he made use of the expressions, and that he heard from some of the inmates that such a practice did exist.

One of the inmates, named Fitzgerald, stated that at one time he saw two parcels containing some union property, and that he informed the master of it at the time, but that he did not bring it before the board.

The master stated that he did not believe one word the man spoke to him about the parcel, and that was the reason why he did not bring the matter before the board.

The guardians came to the conclusion that they saw no reason to attach blame to the porter, but were unable to arrive at any conclusion on the matter on account of the long time that had elapsed since the alleged transactions took place.

The porter got orders to search all parcels coming in or going out of the workhouse in future.

We trust the Irish Local Government Board are well pleased with the part they have taken in causing a medical officer to be removed from his appointment because he "could not get on" with these subordinates. We shall see whether the Local Government Board will have the courage to deal out to these officers—who appear, from the foregoing report, to be charged with misappropriating the workhouse property—as they did with the medical officer, whose guilt was that he would not connive at such transactions even to please the local magnate.

Vegetable Rennet.

In his report on the Royal Gardens at Kew, Sir J. D. Hooker states that his attention had been called to the want of a vegetable rennet for use in India by the report of a Government Commissioner, who stated that "Cheese to be saleable amongst the natives of this country should be made with some vegetable rennet. Natives would not touch cheese made with ordinary rennet, and I am convinced that good cheese cannot be made without the use of some rennet. If a good vegetable rennet could be procured the curd cheeses could be made; they would be cheap, and ryots would soon find a ready sale for them." Failing, after a long course of experiments, to make a good chemical curdling material, Sir J. Hooker hit upon a North-West Indian plant (*Puneeria coagulans*), as possessing the desired qualities. The plant in question is one of the best-known plants in Scinde, Beluchistan and Afghanistan. It bears the name of Puneer-bund (cheese-maker), from its being used by the Beloochies and Afghans in making cheese (puneer) as a substitute for rennet. It has been ascertained that an ounce of the pounded capsules in a quart of water is a very suitable strength for use; a tablespoonful of this decoction coagulates a gallon of warm milk in about half an hour. Seeds of the plant sown have germinated freely, and their further progress will be specially reported upon.

In a communication dated 18th January, to the Hon. Sec., Dr. Norman Kerr, the Archbishop (designate) of Canterbury, in accepting the Vice-Presidency of the Dalrymple Home for Inebriates, expresses his "sympathy and earnest goodwill in the anxious and needful work which you represent."

Proposed Conjoint Examination for Ireland.

We learn that the Council of the Irish College of Surgeons, at its last meeting, resolved, on the motion of Mr. MacNamara:—"That a letter be addressed to the President of the College of Physicians, requesting that his College should appoint a committee of three (3) to take into consideration, in connection with a committee of this Council, the propriety of establishing a conjoint examining board, for the purpose of examining candidates for a double qualification in medicine and surgery; the committee, on the part of this College, to consist of the President, Mr. Wharton, and Dr. Kidd." On Friday last a letter from Mr. Hughes, the Secretary of the Council, on this matter, was under the consideration of the King and Queen's College of Physicians. The College of Physicians have, we understand, appointed three Presidents (Dr. William Moore, Dr. Grimshaw, Registrar-General, and Dr. J. Magee Finny, as a committee; and no better choice could be made. We congratulate the two Colleges upon the enlightened spirit in which they are about to anticipate medical legislation. There cannot be the least objection to the course proposed by Mr. MacNamara, which, at least, will bring about a useful interchange of ideas with reference to the conjoint examination which will be brought into existence by the coming Reform Bill. It may be recollected that about ten years ago the entire subject was worked out by a similar committee, with this difference—that all the licensing bodies in Ireland, save the Queen's University, were conjoined in the effort to effect a combination for examination purposes. The scheme was then actually completed, and finally approved by the Council of the College of Surgeons, and thereupon the extent of the curriculum for the conjoint diploma came to be debated. It was proposed to cut out a course of redundant lectures; and at once the teachers became alarmed for their fees, flew to arms, called the Fellows of the College together, and effectually quashed the whole scheme. We trust that no difficulty about the division of the conjoint fee will arise, and, above all, that the greed of the schoolman or the apprentice farmer will not be permitted to add another to the many useful schemes which they have killed.

Questionable Advertisements.

We called attention last week to an advertisement on the title-page of a contemporary, "Bladder and Prostate in both Sexes. By David Jones, M.D., Founder of, and Physician to, the Home Hospital, Dean Street, Soho. The work contains illustrated diagrams of the cure of stone without cutting, pain, or danger, and numerous successfully-treated cases hitherto regarded incurable." Our attention having been drawn thereto by several correspondents, we sought in vain for name and qualifications of the said David Jones, M.D., both in the official Medical Register and the London Medical Directory. But further inquiry has elicited the following information:—Dr. David Jones is M.D. (Scotland), M.R.C.S., and L.S.A. He was struck off the Medical Register some years since for some serious offence, but is now in large practice, and is proprietor of Bolton House, Clapham Road, and another house in Welbeck Street, W., thus showing of what little consequence registration is as a help to make a practice.

The Risks of Medical Practice.

THE serious danger sustained by a physician of being made the victim of a conspiracy has been fully demonstrated in the notable Hounslow case, and has had a further illustration last week in the case of the dispensary medical officer of Kells, in the co. Meath.

The circumstances of this false and malicious charge were, we believe, as follows:—The prosecutrix, a young girl, came to Dr. Sparrow complaining of morning sickness, headache, and total suppression of menses for the past five months. Suspecting from her general appearance that the patient was pregnant, Dr. Sparrow refused to give any emmenagogue medicine (which she urged him to do) until satisfied that she was not *enceinte*. To ascertain this he, with her full consent, made an examination which fully confirmed his previous suspicions. The patient then left, and the next thing the doctor heard of the matter was a summons for assault. Fortunately, he was able to produce the evidence of three visitors and three servants, who were all within ear-shot at the time, yet heard no outcry.

The magistrates, convinced that the whole affair was "a plot," at once dismissed the charge, and no doubt the lapse of a few months will confirm Dr. Sparrow's diagnosis, and his perfect innocence. We are well pleased to observe that Dr. Sparrow's medical brethren, having satisfied themselves of his freedom from guilt, stood by him in his adversity. In provincial practice it is obviously impossible for a practitioner to have at all times the safeguard of witnesses when it becomes necessary to make gynecological examinations, and it is daily becoming more manifest that charges of immorality against medical men ought to be regarded with the utmost suspicion.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 40, Bombay 26, Madras 34, Paris 26, Geneva 16, Brussels 22, Amsterdam 24, Rotterdam 23, The Hague 25, Copenhagen 31, Stockholm 32, Christiania 28, St. Petersburg 39, Berlin 21, Hamburg 25, Dresden 23, Breslau 26, Munich 28, Vienna 26, Prague 30, Buda-Pesth 22, Trieste 29, Rome 21, Turin 28, Venice 48, New York 26, Brooklyn 21, Philadelphia 23, and Baltimore 28.

THE Hunterian oration will be delivered on Wednesday, the 14th proximo, at three o'clock, by the President of the College of Surgeons, Mr. Spencer Wells, in the theatre of that institution.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 13th inst., fell from 111 to 76, and the death-rate was 17 per 1,000. Diseases of the chest accounted for 45 deaths, and zymotic causes for 5, of which 1 was due to fever and 2 to scarlatina, the intimations of these diseases being for the week 7 and 35.

SMALL-POX AT CATHCART.—Small-pox seems to have broken out at Cathcart, and another worker in the paper-

mills is said to be suffering from the disease. There is every reason to believe that the prompt remedial measures which have been adopted by the sanitary authorities will have the effect of checking the further spread of the epidemic. There is no hospital accommodation in the parish.

ANNUAL MEETING OF THE GREENOCK INFIRMARY.—The annual general meeting of the trustees of the Greenock Infirmary was held on the 18th inst., in the chapel of the Infirmary. Provost Wilson presided, and there was a good attendance. The following is a brief abstract of the 74th annual report:—The total admissions were 1,306, against 1,275 in 1881, being an increase of 31 cases. In the fever house the admissions numbered 365, or 133 fewer than in 1881, the great increase being in the medical and surgical house. The total cases treated to a termination were 1,325, being 86 more than in 1881. The total mortality was 123, against 106 in 1881, or 9.3 per cent., against 8.5 per cent. in the previous year. The visits made by out-door patients to the dispensary numbered 7,040. In the fever house there were 157 cases of scarlatina treated, 86 of enteric fever, and 38 of typhus fever. The ordinary income was £4,638 14s. 5d., against £4,224 19s. 10d. in the preceding year. The ordinary expenditure was £6,092 12s., against £5,823 0s. 2d. in 1881. The excess of ordinary expenditure over ordinary income was thus £1,458 17s. 7d. The extraordinary income consisted of legacies to the amount of £2,281 0s. 8d., of which £1,350 was invested, and there was £411 14s. 2d. of extraordinary expenditure. The sum of £519 6s. 6d. was thus added to the income, and a deficiency of £934 11s. 1d. remained.

EDINBURGH SCHOOL OF MEDICINE.—At a meeting of the lecturers of the Surgeons' Hall division of the school, held last week, a letter of resignation was read from Dr. Keiller, lecturer on midwifery and diseases of women and children. The lecturers accepted the resignation with great regret, in consideration of the long, faithful, and successful service of Dr. Keiller as lecturer on midwifery, and resolved to hold a meeting at an early date to fill up the vacancy in the lectureship. Dr. Keiller was the oldest teacher of midwifery in the medical school. His teaching was sound and lucid, and many far away from Edinburgh will regret that their old teacher has deemed it advisable to retire. The loss to the school will not easily be repaired.

THE GLASGOW CONVALESCENT HOME.—The annual general meeting of the subscribers to this institution, situated at Lenzie, was held on the 16th inst., in Glasgow, Mr. John Pirrie in the chair. From the directors' report it appears that during the year 1,453 patients had been admitted to the Home, being 72 in excess of the previous year. The average stay of the patients was 18 days. The total expenditure for the year was £2,085 2s. 3d., as compared with £2,067 6s. 6d. in 1881. Some exceptional outlay was incurred during the year for renewal of furnishings and repairs. The cost per patient averaged £1 8s. 8½d. or 1s. 7d. per day. There was a falling off in the annual subscriptions—there being £1,061 8s. as against £1,197 4s. in 1881. The contributions, however, from *employés* in public works and collections from churches and schools amounted to £243 10s. 2d., as compared with £229 19s. 6d. for the preceding year. The total revenue from all sources for 1882 was £2,000 18s. 7d., while in 1881 it was £2,110 0s. 9d. The report acknowledged a number of legacies and donations, and conveyed the thanks of the directors to all who had taken an interest in the institution. Dr. Whitelaw afterwards read the medical report, which gave some interesting details as to the patients treated during the year, and said the Home, in the opinion of the medical staff, was worthily fulfilling the purposes for which it had been established.

Correspondence.

HYDROPHOBIA AND ITS PREVENTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The method of Bourrel, referred to by a correspondent in your last issue, is well worthy of trial, though it would be difficult to apply it, owing to the large number of dogs there are in this country. If it were made compulsory by law, then there would be some chance of its universal adoption; until then I am afraid the public, who are so indifferent on the question of hydrophobia and rabies, will not accept it.

But why should the public be expected to be alive to the importance of hydrophobia-prevention, when even the leaders of our own profession seem to be indifferent to supplying the public with useful information on the subject of hydrophobia?

In 1878, Mr. Bennett Stanford, late M.P. for Shrewsbury, offered a prize, of £100 for the best essay on hydrophobia and its prevention, open to the world. The College of Physicians of London were appointed to adjudicate on the essays sent.

The adjudicators, Drs. Brunton, Ferrier, and Dickinson had the tiresome, difficult, and thankless work of reading the essays. Their report was as follows:—

“Royal College of Physicians,
“July 28th, 1880.

“The adjudicators of the Bennett Stanford Essays on Hydrophobia have the honour to report that they have received nineteen essays and communications, of which seventeen were in MS. form and two printed versions. Of the seventeen, eight were considered disqualified, the regulations not having been complied with as to name and motto. Notwithstanding this informality the intrinsic merits of these essays have been weighed in comparison with the others. Of the whole only two essays have appeared to the adjudicators of sufficient merit to be worthy of the prize offered by Mr. Bennett Stanford.

“The one of these, No. 4, with the motto “*Multorum sanorum opus*” (*the work of T. M. Dolan, Halifax*) is the most complete as regards the consideration of all the points suggested by the College. It is an exhaustive *resumé* of all the more important contributions to the literature of rabies and hydrophobia. The most original feature of the essay is an elaborate inquiry—illustrated by maps, diagrams, and police returns—into the prevalence and spread of hydrophobia in the United Kingdom. Considerable space is devoted to the discussion of therapeutic measures, and the author expresses himself hopefully on the subject of treatment. The other, No. 13 (*the work of M. Bourrel*) with the motto “*La science a un caractère universel*” is an excellent account of rabies in the dog, based upon extensive personal observations, over 1,200 dogs thus affected having been under the writer's care. The symptoms and natural history of the disease are well described, and many instructive cases are adduced from the writer's experience bearing on the question of the origin of rabies and the time of its incubation. The writer does not believe in the successful treatment of the malady, but offers many practical suggestions as to its prevention. He attaches most importance to filing the teeth of dogs, the method of effecting which he describes and figures. He also relates practical experiments in proof of the efficacy of the plan he advocates. The essay does not completely follow the suggestions of the College, as it deals only cursorily with hydrophobia in man; but the adjudicators consider that its merits as an original contribution to our knowledge of rabies outweigh this defect, and they would, therefore, recommend that the prize offered by Mr. Bennett Stanford be awarded to the author of this essay. At the same time, they desire to express their high commendation of the learning and research displayed in Essay No. 4, and much regret they cannot award a prize to it also.

(Signed) “H. HOWSHIP DICKINSON,
“T. LAUDER BRUNTON,
“DAVID FERRIER.”

In a supplementary report they say “they are of opinion that both essays, as contributing importantly [underlined] to the knowledge of the subjects in question, are well worthy of publication.”

I send their report, not to find fault with the adjudication—for considering the character of those who were adjudicators, nothing but a just decision could have been given—but to enable your readers to understand the end of the affair. Mr. Bennett Stanford gave the money for the public good. No good

has come of it, except that M. Bourrel personally gained £100, and France had the honour of one of her son's winning the prize. The essays have never been published; they are sealed letters to the public and profession. I have a copy of Bourrel's MS.; I thought it would be worth while to have it published. For that purpose I obtained the consent of the editors of the *Medical Press and Circular* to publish it in their columns, as their paper has been so well known for its communications from all sources on hydrophobia. The consent of the College was necessary. I wrote a respectful letter to Sir W. Jenner, the President of the College, asking, in the interests of humanity, to publish the MS. of M. Bourrel. I received a letter from one of the officials refusing consent, with some elaborate phrases that, if the College thought well, they would publish Bourrel's essays. If I had asked the College to publish my own essay at its expense, I should have expected and deserved a refusal; but as I wished to publish a rival competitor's essay, *free of cost to the College*, and as the interests at stake were so great, I cannot understand the grounds of refusal. Is it not somewhat after the old story of the dog in the manger? Both essays are unpublished, and are, from appearances, likely to remain so.

In 1878, when I was writing my report for the *Medical Press and Circular*, the British Medical Association formed a committee to consider and examine the question. Men of the highest position in the profession were on the committee. They offered to give their services and visit any case of hydrophobia free of charge. I am afraid they were not encouraged. The committee, I presume, is still sitting; if so, in due time, I have no doubt, incubation will be completed, and from their sitting something will be hatched. I have not had the fortune to see, up to the present, any result. With the exception of some enthusiasts, few take any interest in hydrophobia, save when there is an outbreak of rabies imminent. Thus it has ever been in the history of hydrophobia. Times and feelings may change.

Faithfully yours,
T. M. DOLAN.

Horton House, Halifax, Yorks, Jan. 17, 1883.

Royal College of Surgeons, Ireland.—The undermentioned has been admitted a Fellow of this College after the customary examination:—

Francis J. O'Reilly, Trim.

King and Queen's College of Physicians.—At the January examinations the following candidates obtained the licences in Medicine and Midwifery and the certificate in Sanitary Science:—

MEDICINE.—William Thomas Cuthbert, Percy Herbert Delamere, Johnson Gore Hunt, Alan Montgomery Irwin, Francis Saunderson Morrison, Percy Newell.

MIDWIFERY.—William Thomas Cuthbert, Percy Herbert Delamere, Johnson Gore Hunt, Percy Newell, Edward Francis Pigot, Samuel Stronge, West Wheldal, Wilson.

CERTIFICATE IN SANITARY SCIENCE.—George Purcell Atkins, John Byrne Power.

The following Licentiates were admitted Members:—

Montagu, Wm. Perceval.	George Stoker.
Wm. Edwd. Bobson	John Weddick.

Society for Relief of Widows and Orphans of Medical Men.—The usual Quarterly Court of Directors was held on Wednesday, January 10th, Dr. Pitman, V.P., in the chair. Grants to the amount of £1,262 were made to 60 widows, 5 orphans, and 3 orphans on the Copeland Fund. There were no fresh applications for relief. The death of one widow in receipt of £40 per annum was reported. The expenses of the quarter were £80 10s. The deaths of 4 members and the resignations of 2 were announced, and one new member was elected. A Christmas present of £320 had been made in December last to the widows and orphans already on the funds of the Society.

Notices to Correspondents.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves “Reader,” “Subscriber,” “Old Subscriber,” &c. Much confusion will be spared by attention to this rule.

DR. STOKER.—Enough has been said to excite attempts at reorganisation. This has come at an opportune moment, and admirably serves the truth of what has been insisted on by the reforming party,

who will now be enabled to support their claims by a reference to it. There is nothing to explain in the letter.

R. K.—The original splint is in the possession of the Newcastle-on-Tyne Infirmary, and was exhibited at the International Congress in 1881. An account of it appeared at the time of the Exhibition at South Kensington from the pen of Dr. Phillipson, Physician to the Newcastle Infirmary.

DISPENSARY RESIDENCES.—“J. S.” asks: Is a dispensary medical officer bound by any rule under the Poor-law regulations to reside in his dispensary district when a proper house, or even comfortable lodgings, are not to be had in said district in a central part? or can the dispensary committee or guardians compel him to reside in the district when such are not to be had?

[There is no actual rule, and in a few cases medical men are allowed to live out of their districts if their doing so does not inconvenience the majority of patients. But the general rule, and a very proper one, is that the medical officer shall reside amongst his patients. It is altogether a question for the discretion of the Local Government Board and guardians whether he should be expected to put up with any available accommodation. If no accommodation exists a house may be built by the aid of Bruen's Act.—ED.]

SHIP SURGEONS.

In confirmation of our article (Jan. 3rd) on the miserable pay and want of consideration to which surgeons of the mercantile marine are subjected, Dr. Henry MacCormac writes that no satisfactory solution will ever be arrived at until the matter is taken in hand in the House of Commons. He says: “It ought not to be optional to screw down the reasonable remuneration of marine medical officers to a miserable pittance as frequently happens. The pay ought to be on a parity with that of the highest class of army and navy surgeons, with a further allowance set apart for superannuation, or otherwise a life assurance, so that the medical man, when, owing to disease, accident, or advanced years, he could no longer exercise the duties of his profession, should not be thrown adrift without resource. The assurance or superannuation ought not to be less than a thousand pounds, and the minimum of pay twenty pounds a month, and at least that sum for any run, however short. But these are matters of detail which could be arranged by a medical commission. The labourer is worthy of his hire, and science, humanity, nay common morality, are alike insulted in regard to the wretched pecuniary return now awarded medical officers serving in our great commercial marine.”

DR. J. W. MARTIN (Sheffield).—Cases received.

A NEW DELICACY.—“Well, madam, how's your husband to-day?” “Why, doctor, he's no better.” “Did you get the leeches?” “Yes, but he could only take three of them raw, Sir; I had to fry the rest.”—*Students' Journal*

MR. RANKINE (Sunderland).—We will answer your query in our next, or by private note, after due inquiry.

DR. C. R. F.—The case is an interesting one, and shall appear in an early number.

DR. BELL AND THE ANTI-VACCINATORS.—A correspondent sends us a copy of the *St. Pancras Gazette* (January 18th), in which appears an account of nearly three columns of an anti-vaccination meeting held last week in the St. Pancras Vestry Hall to protest against a continuance of compulsory vaccination. The meeting was harangued at considerable length by Mr. Wm. Jebb, a well-known agitator, who used the customary stock arguments (which have been over and over again refuted) to the apparent delight of his audience. Before putting the proposed resolution, the chairman asked if any one wished to make any remarks in opposition; whereupon Dr. Bell stepped upon the platform and protested that, as the country had passed this very wise law, which he contended should and would be sustained, it was an inquiry to encourage ignorant and prejudiced people to break it. The Vaccination Law was the best we had. The opponents had nothing better to offer. The chairman, he said, had alluded to the effects of sanitation; but were they to suspend vaccination until sanitary laws were perfect?—Mr. Harding: Yes.—In reply, Dr. Bell scored a point—which was met with loud laughter—by exclaiming: I hear an undertaker's voice!—There were three vestry men whose voices were loudest in granting the use of this hall for this meeting, and they were undertakers, and that was very appropriate.—Of course the resolutions were declared carried, as, with the exception of Dr. Bell, none were present but anti-vaccinators; but an impromptu remark sometimes sets people thinking, and the combination of “undertaking” and anti-sanitation might lead thoughts in an opposite direction to that intended.

INQUIRER.—Ordinary Court dress would be *de rigueur* on presentation.

ARTIFICIAL EYE.—“Myositis” says: A lad, about 14 years of age, has a very obvious cataract of nearly lustre in one eye. Could he wear an artificial eye with comfort and without injury to the conjunctiva? and, if so, should it be removed at night?

[Certainly not. An artificial eye placed over an eye of normal size would be sure to set up destructive inflammation.—ED.]

QUININE MIXTURES.—“T. E. C.” writes: 1. Can you recommend any method of combining quinine with alkalies besides the quino-alkaline mixture? 2. Is it not probable that most of the quinine passes away in the faeces when administered in the quino-alkaline form for want of a solvent medium, inasmuch as the acid of the stomach is neutralised? 3. Is it possible to produce cinchonism by the quino-alkaline mixture?

[1 and 3. We take it for granted that our correspondent refers to the alkaline mixture of quinine recommended by Equire in his “Pharmacopœia of the London Hospitals,” 4th edition, page 142. Each ounce of this mixture contains gr. ii. of quinia sulph., gr. ii. of ammonium carbonate, and gr. xx. of potassium carbonate, flavoured with a little chloroform. In using this formula we employ sodium carbonate, which is easier taken. This mixture is absorbed by the stomach and upper portion of the small intestines, and would, if given in sufficient

quantity, undoubtedly produce cinchonism. 2. Quinia sulphate, whether taken in the acid alkaline, or even solid form, does not pass off in the faeces unless it be given in very large doses. A respiratory power of 3,000 c.c. will, according to Kerner, destroy fifteen grains of quinia sulphate in twenty-four hours. Anything over this will pass into the urine.—Ringer's Therapeutics, 9th edition, p. 622.—ED.]

MEETINGS OF THE SOCIETIES.

HUNTERIAN SOCIETY.—This evening (Wednesday), at 7.30 o'clock, Special Council Meeting.—8 o'clock, Mr. G. T. B. Stevens, “On a Case of Bullet Wound of the Skull.”—Dr. Woakes, “On Vertigo and the Group of Symptoms sometimes called Mènière's Disease.”

ROYAL INSTITUTION.—Thursday, Jan. 25th, at 3 p.m., Professor Dewar, “On the Spectroscope.”

CLINICAL SOCIETY OF LONDON.—Friday, Jan. 26th, at 8.30 p.m., Opening Address by the President.—Dr. Longhurst, “On the Activity of the Infective Power of the Poison of Scarlet Fever during the Pre-eruptive Stage of the Disease.”—Mr. Shuter, “On Sub-peritoneal Amputation at the Hip joint” (patient to be shown).—Dr. Broadbent, “On a Case of Supposed Hydrophobia treated by Chloral, with Recovery.”—Dr. Samuel West will show a Case of Diffuse Ecleroderma.—Dr. Ledard will show a Case of Oestitis Desformans.

Vacancies.

Central London Sick Asylum District.—Assistant Medical Officer and Dispensary. Salary, £100, with board and residence. Applications to be forwarded to the Clerk to the Managers, Cleveland Street Asylum, Fitzroy Square, W.

Falkland Islands.—Medical Officer to reside in the western of the two large islands. Salary, £300. For further information applicants should address the Private Secretary, Colonial Office, London.

Glenamaddy Union, Dunmore Dispensary.—Medical Officer. Salary, £34, and £10 as Medical Officer of Health. Election, Jan. 27th.

Lisnaskea Union, Maguire'sbridge Dispensary.—Medical Officer. Salary, £30, and £15 as Medical Officer of Health. Election, Feb. 1st.

Royal Surrey County Hospital.—House Surgeon. Salary, £74, with board, &c. Applications to be sent to the Assistant Secretary on or before Feb. 6th.

Stranorlar Union, Killygordon Dispensary.—Medical Officer. Salary, £100, and £20 as Medical Officer of Health. Election, Feb. 2nd.

Appointments.

DE BENNY, A. C. C., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer to the Workhouse of the Scarborough Union.

FIRTH, E. H., F.R.C.S. Eng., Demonstrator of Anatomy in University College, London.

FISHER, F., M.R.C.S., Medical Officer for the North Deptford District of the Greenwich Union.

HEAD, R. T., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Fulbourn District of the Chesterton Union.

HESLOP, F. A., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Overbury District of the Tewkesbury Union.

IRVINE, Dr. J. J., Medical Officer of the Clonmany Dispensary, Innishowen Union, Ireland, and Medical Attendant to the Local Constabulary.

KING, D. A., M.R.C.S., Casualty Physician to St. Bartholomew's Hospital.

LANE, J. O. B.A. & M.B. Cantab., M.R.C.S., House Surgeon to the General Infirmary, Northampton.

LUCAS, E., M.R.C.S., Medical Officer for the Fereham District of the Chesterton Union.

Births.

MURPHY.—Jan. 16th, at 18 Harcourt Street, Dublin, the wife of Dr. Murphy, of a son.

WALKER.—Jan. 16th, at The Elms, Parkhurst, Isle of Wight, the wife of George E. Walker, L.R.C.P., of a son.

Marriages.

THEED—LINDSEY.—Jan. 18th, at St. Mary's, Plaistow, Kent, William Cawood Theed, of Leicester, M.R.C.S. Eng., to Millie, third daughter of Mark Lindsey, Esq., of Bromley, Kent.

Deaths.

DOWSON.—Jan. 6th, at Middlesborough, John Dowson, M.D., M.R.C.P., late of Whiteley, aged 84.

FORSYTH.—Jan. 14th, at Selborne Road, West Brighton, Sir John Forsyth, C.B., K.C.S.I., late Principal Inspector-General of Her Majesty's Indian Medical Department (Bengal), and Honorary Physician to the Queen, aged 84.

LOBBAIN.—Jan. 12th, W. J. Lorraine, M.R.C.S. & L.R.C.P. Ed., of Drury Lane, Wakefield, aged 85.

MACKINNON.—Jan. 16th, at his residence, Millbrook, near Southampton, Charles Mackinnon, Inspector-General of Hospitals, Bengal Medical Establishment (retired), aged 83.

M'KAY.—Jan. 14th, suddenly, at his residence, Dromore Street, Ballinacree, David M'Kay, M.D., aged 84.

MIDDLETON.—Jan. 16th, at 17 Stratton Place, Portobello, N.B., John Middleton, M.D., L.R.C.S.

MUNRO.—Jan. 13th, at Bishops Teignton, Devon, suddenly, Dr. Munro, formerly of Clunhill, Forres, aged 73.

OTTLEY.—Jan. 14th, at Ledbrooke Grove, Notting Hill, W., suddenly, Walter Ottley, M.B., F.R.C.S., aged 33.

PHAYRE.—Jan. 16th, at Belmullet, of general debility, Alexander Raleigh Phayre, M.D., of Drumcondra Hill.

SHINKWIN.—Jan. 16th, at 4 North Mall, Cork, Thos. Crofts Shinkwin, M.D.

The Medical Press and Circular.

THE WORK OF THE CLINICAL SOCIETY OF LONDON. (a)

By ANDREW CLARK, M.D., F.R.C.P.,
Senior Physician to the London Hospital.

DR. ANDREW CLARK, on assuming the Presidential Chair of the Clinical Society of London, commenced the usual inaugural address by acknowledging the honour conferred upon him, which, he averred, differed from any mark of distinction obtained through influence or patronage, inasmuch as it was the spontaneous offering of the profession, and possessed, consequently, a higher and more distinctive value than any other that could be tendered to its recipient. His accession to office marked a new epoch in the history of the Society, and he thought that, standing as he did, midway between its past and future, the occasion offered a favourable opportunity for profitable inquiry into the nature and influence of the Society's past achievements.

A careful examination of the work accomplished during the reign of his deservedly illustrious predecessor Mr. Lister, would reveal the fact that the two volumes containing the record of that work compared most favourably with those appertaining to any previous period of corresponding length; they exhibited no lack of valuable productiveness, or of the foresight so necessary to good results; and it was observable that the work, generally, was progressively of a higher and truer description, thus indicating the important service which the Society was slowly accomplishing. It helped to extend the best kind of knowledge, and to perfect the best kind of practice; while it exerted very considerable influence on individual scientific workers. It not only encouraged good labourers but it repressed the

bad, and this principally by creating a standard of work from the existence of which the utmost benefits accrued. In respect to the younger members of the Society this influence was particularly apparent. Their work was of a more careful description than heretofore; they exhibited greater caution in formulating conclusions, and gave graver consideration to the value of their problems; while in a multitude of ways they showed improvement, consequent on the inculcation of higher and better principles of action. The change affected, also, the personal relations of their members; a readier appreciation of merit, and a kindlier tolerance of weaknesses had sprung up, and there was a general willingness more than formerly to admit the claims of superiority and of earnest research.

But though it had done so much to cultivate these virtues among its members, the Society had done even more for medicine by repressing what Dr. Clark stigmatised as "bad workers," of whom, he asserted, there were ten to one "good." His description of such men endowed them with every showy accomplishment found in the shallow but versatile physician; sharpness, superficiality, and marvellous aptitude at seizing the results of laborious and honest research were given as their special characteristics; and as a consequence, it was said, they flooded the literature with unworthy, even if not unvarnished papers on every subject. Their favourite hunting-ground, however, was therapeutics; and that, while their achievements were practically limitless, they affected to pity and despise those "studying in the narrow path."

In another way the capacity of the Society for useful work was likewise very great, namely, in demonstrating the true relations between pathology and the clinical study of disease, and especially by its recognition of the importance of dynamical conditions as of superior moment to the statical manifestations exhibited on the post-mortem table. In order to understand the full meaning of such change, assistance must be obtained from all the sciences cognate to medicine, in order that a true appreciation of clinical phenomena might be arrived

(a) Abstract of Presidential Address delivered before the Clinical Society, Friday, January 26th.

at. Even the best of the results derived through pathological experiment—invaluable and essential though such experiments are—were surrounded by subtle difficulties, and oftentimes undue weight was attached to these results through fallacies committed in arguing from animals to men, and ascribing occurrences under abnormal conditions in the latter, to causes which produce effects of similar appearance in the former. A first interpretation of any results so obtained was only possible after appeal to clinical medicine, which alone yielded the criterion for just and reasonable conclusions. These principles, however, have not, Dr. Clark insisted, exerted their due weight in recent years, and hence it is that follies have been committed like that of comparing a seton in the neck of an animal to that, with its effects, in the neck of a man; or of likening tuberculosis, as it occurs in rodents, to the disease so named in the human being, &c.

It afforded occasion for rejoicing that the Society was still imperfect as regarded its work, a stimulus being thereby provided for further endeavour; and one of its defects was exhibited in the incompleteness of reports of cases presented by its members, such reports being deficient in information respecting the outside history of the cases. Such reports, in order to be competent to teach, ought to be whole, and to include more than merely the family and individual histories; and to obtain assistance in this respect from all related sciences. Individual cases were undoubtedly valuable, but they would be much more useful if made as perfect as could possibly be; and extending the analogy thus afforded it might be advanced that, as the German Renaissance of medicine was preeminently due to the association together of physicians, physicists, chemists, physiologists, and pathologists, so might it be anticipated that the importation of scientific aid to his own purposes would hasten the period of complete usefulness of the modern clinical observer.

Neglect of minute details easily to be observed in connection with the daily life and habits of patients was described as a serious fault of the present time among practitioners, and to it could be attributed much unsound and incorrect treatment of disease. Chronic diseases were the outcome of violation of physiological laws, united with individual characteristics; and their nature might easily fail to be recognised by all but skilled observers trained to appreciate minute deviations from the normal. When relieved, however, from unphysiological influences, the organism tended to recover, an instance to the point being afforded by chronic gastric catarrh. Patients suffering from this complaint were usually ordered to take light and nutritious food, and undergo moderate exercise, while for medicine they were ordered an alterative, and mild aperient, with tonics, &c. In such cases management in respect to details was of the utmost importance, and obedience to physiological laws essential. The meaning to be attached to the term "light nourishment" admitted of widely different acceptations, so that even a well-intentioned patient could very well be involuntarily guilty of extreme errors. Every case of this kind should be managed with a view to physiological conditions in regulating the amount of food to be taken, the time for taking it, its nature, &c., &c. Dr. Clark quoted in illustration a case to which he was called in consultation about eight years ago. The patient had been ill for many weeks, and had been brought from Wales to obtain further advice in town. This recommended a method of treatment distasteful to the patient and his friends, and Dr. Clark was summoned to utter its final authorisation, or otherwise. The patient, a man about 60 years of age, was weak, depressed, short of breath, suffering from palpitation, with furred tongue, fetid breath, and distended abdomen, discharging ill-smelling gases *per anum*, and was found to have an enlarged liver and heart, legs blue, cold, and cedematous, lungs congested, and urine sp. gr. 1010, containing slight amount of albumen. He was

also troubled with cough. He had been subjected to treatment with a view to restoring a delicate constitution, and had been in the habit of taking ample supplies of food and drink at frequent intervals. He was really in peril, not of the malady from which he suffered, but of the means adopted for relieving it, and Dr. Clark's opinion coinciding with that already expressed on the case by his *confères*, the patient was at once ordered to adopt a precise and severe regimen, to eat regularly and lightly, with a strict allowance of liquids; calomel and aperients, with tonics, being the medicinal agents employed. In three days no improvement was experienced, and the patient expressed a desire to return to his former customary diet, but being persuaded to persevere, on the fifth day he grew better, and after three months he was well, except as regarded a weakened heart, and slight renal mischief. So long as he observed the rules laid down for his guidance, his health remained good; but sometimes he threw over all precautions, and after a period of high living and excitement, became reduced to his former debilitated condition, out of which he would voluntarily rescue himself by resorting to a stricter mode of life.

This case typical of a large class, illustrated the need of observing physiological laws and minutely obeying them in all respects. It was true that some persons were so constituted that restoration of their health must be impossible of achievement, but apart from these a vast number continued to endure suffering because of the derision in which physiological laws were held.

Dr. Clark commented on the striking fact that the Society's volumes contained no studies of the diseases associated with particular organs and tissues, of ailments seemingly trivial or unimportant, but capable of teaching many valuable lessons if carefully investigated. He alluded to such things as temporary aphasia in adults, renal inadequacy, the glycosuric storms of the gouty, &c.

Reference was made also to the omission of all reports of discussions held on the papers reported in the Society's volumes of "Transactions." The cases themselves, said Dr. Clark, were admirable, but their value would be doubled if they were presented side by side with the debates to which they gave rise. He thought, also, that the reply of the author should always be freely reported, especially since the usually careful and accurate reports of society meetings in the journals omitted this part of the debate. The address concluded with advice respecting the future conduct of the Society, and the work of its members. This, it was urged, should be undertaken with justly tempered mind, and always with the remembrance of the burdens imposed by professional life; to its execution should be brought gravity and diligence, while an appreciation of the responsibility incurred with every case ought to be prominently in the mind. On the apt and correct performance of a practitioner's duties there depended, not only individual, but even national well being. Such reflections might well stimulate to self-sacrifice in overcoming our ignorance of disease.

The Lettsonian Lectures

ON

THE TREATMENT OF SOME OF THE FORMS OF VALVULAR DISEASE OF THE HEART. (a)

By A. ERNEST SANSOM, M.D., F.R.C.P. Lond.,
Physician to the London Hospital; Senior Physician to the North-Eastern Hospital for Children, &c.

(Continued from page 69.)

LECTURE II.—MITRAL REGURGITATION.

Morbid Anatomy—Mitral Regurgitation in Anæmia, in Neuroses of the Sympathetic, in Acute Fevers, in Rheumatism, and in Conditions of High Arterial Tension—Treatment to Restore

(a) Delivered before the Medical Society of London.

Compensation—Digitalis—Belladonna—Cassa—Caffeine—Convallaria Maialis—Morphia—Alkalies—Iodides, &c.

I HAVE to ask your attention this evening to the subject of the treatment of various conditions of disease associated with a certain imperfection in the mechanism of the heart—an imperfection of closure of the left auriculo-ventricular orifice at the time of systole, which occasions the reflux of a portion of the contents of the left ventricle into the left auricle. The mitral valve is inadequate to close the orifice.

Pathological anatomy teaches that such result may be brought about by several varieties of morbid change:—

1. By dilatation of the left ventricle without structural disease of the valve, so the free borders of the curtains are drawn upon by their circumferential attachments, and prevented from a perfect apposition in systole.

2. By the changes in the valve-curtains, the tendinous cords and fleshy columns induced by endocarditis, and the changes consecutive thereto. Vegetations about the orifice may prevent its perfect closure, or the valve being thickened its segments may be imperfectly co-apted; or curtains, cords, and columns any, or all, may be sbrunken, thickened, fibrous, or cartilaginous from sclerous change; or from deposit of earthy salts, the valve and orifice may be hard and calcareous.

3. The valve-curtains, cords, or columns may become inflamed, and therefore incompetent. It has been supposed that this may occur from sudden strain in a healthy heart, but Dr. Wilks and Moxon have given strong reasons for the conclusion that there must have been some dilatation, at least of the left ventricle previously. They consider that this accident is not of infrequent occurrence. They say, "the snapping of an overstrained mitral tendon in a dilated heart we believed to be a relatively very common cause of severe heart disease, converting the very bearable trouble into a hopeless disablement." (a)

4. Patches of atheromatous disease may be observed upon the valve with consecutive degenerative change rendering it inadequate.

5. Portions of the valve and the surrounding structures may be destroyed by ulceration.

Such are in brief the changes which are observed on post-mortem examination to render perfect closure of the left auriculo-ventricular aperture impossible.

Mitral regurgitation is, however, not to be wholly interpreted by pathological anatomy. It is to clinical investigation that we must chiefly look for guidance. We ask ourselves, first: by what sign observed in the living body do we infer that the mitral orifice is incompletely closed in systole? The answer is that there is a consensus amongst observers that a murmur heard with the first sound at the apex of the heart, localised at this point, conducted externally towards the left axilla, or to the back in the neighbourhood of the angle of left scapula indicates that there is in existence a condition permitting regurgitation into the auricle. The sign is almost, though not quite, pathognomonic. The only condition with which it is likely to be confounded is, in my opinion, pericardial roughening at or about the apex. I have never known a difficulty about the differential diagnosis in the case of adults, but I have observed such difficulty several times in children. In cases of children, I have repeatedly seen that the quality, character, and situation of a systolic murmur will not declare with precision whether there is exocardial or endocardial disease. The house-physicians at the North-Eastern Hospital for Children have observed this with me. A murmur which has been ascribed to mitral regurgitation by competent observers has been proved on post-mortem examination to be due (in the highest probability), to roughening of, or fibrous exudation on the pericardium in the neighbourhood of the heart's apex.

The difficulty of diagnosis is, however, an infrequent one, and we may conclude that in a vast majority of cases the existence of a murmur having the characters which I have mentioned indicates a condition of mitral regurgitation.

Combined clinical and necroscopic observation, however, soon convinces us that in certain cases wherein we have determined from such physical sign that mitral regurgitation existed during life, no lesion indicating inadequacy of the mitral valve to close its orifice has been discovered after death. Moreover, in some cases where we have not only observed the sign mentioned, but where the whole

category of signs, symptoms and consecutive changes which experience has taught us to associate with mitral inadequacy has been present, the autopsy has demonstrated no determinate lesion at the orifice.

It will best serve a practical purpose, I think, if we divide the cases in which the signs indicating mitral regurgitation are evident into clinical groups, discussing the bearing of the collateral signs upon treatment in each group. We shall thus consider the cases just as we meet with them in practice.

I. A case presents itself manifesting signs indicating mitral regurgitation in the subject of marked anæmia. We have to inquire whether or no there has been antecedent disease leading up to organic changes at the mitral orifice. Supposing such signs are not in evidence, have we a right to assume that actual mitral regurgitation can be induced by the condition of anæmia without concurring causes? The answer is, in my opinion, undoubtedly in the affirmative. In cases of anæmia and chlorosis a murmur is sometimes observed exactly in the site of that indicating mitral regurgitation. I have observed not only this sign, but all the concurring signs of cardiac failure, in a woman who suffered from excessive periodic hæmorrhages *per vaginam*, associated with uterine fibroids. I was called to such a case—Mrs. H., æt. 39. She manifested severe dyspnoea, such as one meets with in cardiac disease, extensive œdema, and a loud systolic murmur heard at the apex of the heart. She was very anæmic from copious hæmorrhage, the cause of such hæmorrhage having been diagnosed by Mr. Spencer Wells to be uterine fibrosis. With care, rest, and suitable treatment she recovered from all the symptoms denoting cardiac disease, and the murmur wholly disappeared. This I consider to have been an instance of what Prof. Balfour has termed "curable mitral regurgitation."

In the disease known as progressive pernicious anæmia, it is common to find an apex systolic murmur. Such was noticed in four of eight cases recorded by Dr. Byrom Bramwell. In one an observer had diagnosed the case as cardiac dropsy from mitral insufficiency (a). In three cases recorded by my colleague, Dr. Stephen Mackenzie, an apex-systolic murmur was noted. Though in many of such cases the murmurs are heard at the base of the heart and over the site of the pulmonary artery, they are, as Dr. Stephen Mackenzie has said, "loudest at the apex of the heart, conducted into the axilla, and heard at the angle of the left scapula. It is remarkable how loud and harsh these bruits sometimes are." (b)

A series of phenomena strictly analogous to those just mentioned as occurring in the human subject can be induced in animals by copious bleedings. Dr. Donald MacAlister says: "When an animal is bled till it is feeble, a murmur indicating regurgitation from the ventricle is heard with the heart sounds. You may inject a proper saline solution to make up the normal quantity of circulating fluid, but yet the regurgitation occurs. As the animal makes blood again, so that its muscles are again properly nourished, the murmur disappears." (c)

And now, assuming that in these cases there is a veritable regurgitation, how is such brought about? The explanation is, I think, given by the careful experiments conducted by Ludwig and Hesse at Leipzig, which have been admirably summarised by Dr. Donald MacAlister. (d) The mechanism for the closure of the left auriculo-ventricular orifice does not reside in the valve-curtains alone, the surrounding muscles of the ventricle have an active share, not merely in floating up the valve-curtains, but in reducing the size of the aperture which these valve-curtains have to close. In Dr. MacAlister's words: "As systole begins the muscles surrounding the ostia contract; and presently, instead of the round gaping orifices of diastole the valves have to close oval and compressed ones. . . . The base muscles do their share of the work of closure, the valves promptly complete it." When the muscles of the base are enfeebled, as in the cases which we have been considering, the valve-curtains are insufficient to close the orifice, because such orifice is wider than usual. It is not that the orifice is dilated, but that it is insufficiently contracted, the aid of the muscles which normally produce such contraction being in abeyance.

(d) "Remarks on the Form and Mechanism of the Heart." *Loc. cit.*

(a) Cf. "Pathological Anatomy." By Drs. Wilks and Moxon, 2nd Edition, London: Churchill, 1875.

Regurgitation may result, therefore, from mere feebleness of muscle, and restoration to the normal may occur, with improved nutrition; but it must be recollected that persistent anæmia or repeated blood-letting (as shown by experiments on animals) will induce a fatty degeneration of the heart-muscle, a morbid condition which may be irrecoverable.

I think it will be agreed that, both for prognosis and treatment, it is important that we should be able to make the differential diagnosis between a regurgitation due to feebleness of muscle the result of anæmia, and organic disease at the mitral orifice. I will suppose that in a case of anæmia, presenting a systolic murmur at the apex, there is no evidence to lead us to suspect previous valvular disease, and no history of rheumatism. It may be, however, that the regurgitation is not from adynamia of the ventricle, but from an endocarditis of insidious origin, such as I have previously described. Can we rely for guidance on the physical signs? I will mention an illustrative case. I was called a short time ago to a patient at the London Hospital who was supposed, after the preliminary examination to be suffering from mitral disease. There was a loud apex systolic murmur, typical of mitral regurgitation. On delineating the outline of the heart by percussion, however, I noted that there was no notable dilatation such as one would expect to find in organic heart disease where failure was imminent, for the patient was extremely ill. Noticing the extreme pallor, I suspected that this might be a case of idiopathic pernicious anæmia, and in confirmation of this view I found the fundus oculi on both sides studded with abundant hæmorrhages. I have no doubt, both from these reasons, and from the clinical history that this was a case of mitral regurgitation in association with pernicious anæmia. Unfortunately, the patient being a Hebrew, an autopsy was not performed.

I would insist, therefore on the value of *determining the outline of the heart by percussion* as a means of differential diagnosis in these cases. In anæmia, as I have observed, the heart is not notably dilated, in fact as in the case cited, the outline of cardiac dulness is usually rather small. (a)

In the case I have mentioned as occurring in conjunction with hæmorrhage I found the *determination of the tension in the arterial pulse* to be a very important means of differential diagnosis. In advanced organic mitral disease—when, for example, as in the case cited, dropsy and extreme cardiac dyspnoea have supervened—the arterial tension is low. In the case mentioned I found the opposite indication—the tension as shown by the sphygmographic tracing was rather high. It is an unexpected thing, as Dr. Broadbent has pointed out, that, “in a disease such as chlorosis, characterised by debility, there should be high arterial tension, but such was the fact.” (b) My experience is, in this particular, entirely in accord with Dr. Broadbent's.

These two signs, therefore, an area of cardiac dulness not perceptibly greater than the normal; and a heightened tension in the systemic arteries, I consider to be of the greatest importance in differentiating in a very anæmic patient, between organic disease at the mitral orifice, and incomplete closure from adynamia.

As regards treatment, such differentiation is important, for I have never known in the class of cases we are now considering any marked improvement follow the administration of the usual cardiac tonics, such as digitalis and iron. As regards the cases attended with hæmorrhage, it is, of course, of the first importance to arrest this at its source. Rest and the administration of assimilable food are no less important indications. In this connection, I may call attention to the great value I have observed to attach to *supplementary alimentation by the rectum* in such cases. I have long tried the plan of using defibrinated ox blood as a nutrient enema, as advocated by my friend, Dr. A. H. Smith, of New York. In comparing results, however, with those in which artificially-digested food was employed, I felt that the balance of evidence was in favour of the latter plan. I have had prepared mixed peptone enemata—beef, milk, and farinaceous food—which have been proved to preserve a perfectly good condition for long periods.

(a) Dr. Allbutt has found that in progressive pernicious anæmia, the heart is not dilated but simply atrophic. Dr. Theodore Williams has shown that some cardiac hypertrophy often follows anæmia, but dilatation is not evidenced. (A discussion on Prof. Balfour's paper “Arguments in favour of Dilatation of the Heart as the Cause of Cardiac Anæmic-murmurs, &c.” *British Medical Journal*, August 26, 1882, p. 854.

(b) *British Medical Journal*, August 26, 1882, p. 856.

These have the advantage of being available at a moment's notice, it being only needful to render them diffident with warm water. From two to four ounces are injected slowly into the rectum, and repeated every three or four hours. In many cases I have caused to be added the dried ox blood (*sanguis bovinus exsiccatus*), in the proportion of a drachm to the ounce. I have lately, however, used a simpler plan with good results, using, instead of peptoned food, equal parts of warm milk and cod-liver oil as a nutritive enema.

In the treatment of cases of idiopathic anæmia, I have found no drug treatment so efficient as the administration of arsenic (Fowler's solution in small doses gradually increased). I have observed, as has been recorded by others, complete recovery, with the disappearance of the cardiac murmur, under such treatment, combined with rest and careful nutrition.

It has been supposed by Nannyn, Balfour, and others that actual regurgitation through the mitral orifice is in existence in cases where a systolic murmur is observed in the second left interspace near the border of the sternum. I am far from convinced such view is correct, and prefer to adhere to the opinion that such murmurs are generated usually in the pulmonary artery. A consideration of this debatable question is unnecessary here as I am dealing with those conditions in which observers would generally agree that mitral regurgitation was undoubtedly indicated.

II. We will now assume that a systolic apex-murmur is present in a patient showing signs of a *neurosis of the cervical sympathetic*. It has been frequently noted that a murmur at the apex has existed in the subjects of exophthalmic goitre (Graves' or Basedow's disease); yet on post-mortem examination no disease at the mitral orifice has been discovered.

In these cases anæmia may be present, but not of necessity. It is not causally related with the phenomena. Organic heart disease may co-exist, but such coincidence is rare. It is important to recognise, especially with regard to treatment, that in the subjects of Graves' disease mitral regurgitation occurs without valvular lesion. I now wish to draw attention to a point with reference to the curious disease called exophthalmic goitre, that, as I have myself observed the triad of symptoms—the protrusion of eyeballs; the thyroid enlargement; the paroxysmally-disturbed, rapid, palpitating heart—can be disunited; and we may observe in a given case a union of two of the groups of symptoms, or even one group alone. For example, I lately brought before the Ophthalmological Society a patient manifesting pronounced exophthalmos, without thyroid, or cardiac symptoms. I have lately seen in consultation a case manifesting only the cardiac phenomena, the heart's action being extremely rapid and the paroxysms of palpitation extreme. Again, I have lately observed the case of a lady in whom there is a combination of the cardiac and thyroid symptoms without exophthalmos. In each of these cases there was a history of shock, mental anxiety, or nervous exhaustion, as a proximate cause. In the last case the cardiac trouble was severe: besides distressing paroxysms of palpitation a loud murmur was manifest at the apex and extensive and extensive œdema supervened. In fact, the case closely resembled one of organic mitral disease. There can be but little doubt, I think, that in this group there is disorder, if not disease, of certain ganglia of the cervical sympathetic. The record of fatal cases in which such disease has been actually demonstrated is now tolerably extensive. Trousseau, Cruise, and McDonald, Ruth, and Shingleton Smith have recorded cases in which some of the ganglia (usually the inferior cervical) have been enlarged, atrophied, or degenerated. Such observations have a distinct bearing on treatment. In the cases which I have seen ordinary tonics and digitalis have been of very little benefit, but great improvement has followed galvanisation of the cervical sympathetic. I have employed the continuous current from 20 to 40 elements (Léclanché). One pole may be placed behind the lower jaw in front of the sterno-mastoid, and the other upon a corresponding point of the opposite side, or at the nape of the neck right or left of the vertebra prominens, or above the sternum at the inner edge of the insertion of the sterno-mastoid. (a)

(a) Such treatment has been recorded as successful by Von Dusch, Chvostek, Moritz Meyer, Eulenberg, Guttmann, Remak, Ancona, and others. Cf. Althaus' “Medical Electricity,” third edition, pp. 165, et seq., 335, 621. Hayden “Diseases of Heart and Aorta,” pp. 1050, et seq. Ancona “Giornale Veneto delle Scienze Mediche,” *British Medical Journal*, June 1st, 1878, p. 790.

III. I now turn to a third group of cases, and assume that the indications of mitral regurgitation are manifest during the evolution of certain fevers. In the course of typhoid fever, for example, a systolic murmur is discovered at the apex. There is no history of its existence before the attack, but it has arisen during the course of the disease. M. Hayem has especially studied these phenomena; he says: "In the course of, or at the end of the second week, there arises, in a certain number of patients, a bellows murmur within the systole. At the time of its first appearance, this murmur may be soft and of little intensity. Its maximum is at the apex in the neighbourhood of the nipple, but it is prolonged towards the base, becoming feebler there. Often this bruit has an intensity and roughness equal to organic murmurs, or at first of only slight intensity; it may become louder rapidly, and make one believe in the existence of endocarditis; moreover, it may vary in intensity from day to day, or may become modified by a change of position of the patient, as one may observe when auscultating in the lying and sitting position alternating." (a) In typhoid fever, therefore, there may be important questions as to the nature of such a murmur, and its bearing on treatment. The clinical evidence shows that in the course of the fever the murmur changes its site and fades away, and that it is accompanied by reduplication of heart-sounds and disturbances of cardiac rhythm. Thus, in the case of a young lady, *æt.* 19, observed by myself, there appeared on the eleventh day of typhoid fever a soft systolic murmur, left of the sternum, at the third costal cartilage; on the thirteenth, the bruit extended nearly as far as the apex; on the fifteenth, it extended to the apex; on the seventeenth it was right of the apex, and there was reduplication both of first and second sounds; on the nineteenth, twentieth, and twenty-first days reduplication of the first sound only was heard, the murmur having disappeared.

The murmur, therefore, is an evanescent one. To what is it due? The changes are, according to Hayem's observations, not in the endocardium nor pericardium, but in the muscle of the heart. In fatal cases, the muscular fibres present a granular and fatty degeneration, or a special form of vitreous generation; the areas of morbid change are disseminated in an irregular manner here and there throughout the cardiac muscles. There are, besides, a multiplication of the muscular nuclei, and an aggregation of cellular elements. In fact, the disease is a form of myocarditis.

It is, I think, sufficiently proven that the murmur occasionally heard at the apex in cases of typhoid fever is due to regurgitation on account of imperfect apposition of the valves of left or right sides, from enfeeblement by disease of the muscular fibres in certain areas of the heart wall. It does not appear that the occurrence of murmur renders the prognosis more grave, but sudden death in all probability from myocarditis may occur in typhoid without any special evidence of direct cardiac impairment previously.

Its occurrence, however, should make us watchful, and cases presenting any of the phenomena indicating myocarditis in typhoid should be observed and treated with a view of preventing subsequent dilatation.

Analogous myocarditis has been described in variola (by MM. Desnos and Huchard), (b) and in severe forms of intermittent fever, as observed in Africa (by M. Vallin). (c)

It is obvious that a recognition of the nature of the alteration which produces a mitral regurgitant murmur in the cases we have been considering must have an important bearing on treatment. We need not fear that endocarditis has arisen as a complication, nor have we to debate as to an anti-rheumatic plan of treatment. The indication is to keep the disturbed muscle of the heart as tranquil as possible, and, of course, to promote as good a nutrition as the circumstances will permit.

IV.—I now come to the fourth group, and assume that a murmur indicating mitral regurgitation is observed in the subjects of acute or sub-acute rheumatism. Attention has been frequently drawn to the fact that murmurs may arise in the course of evolution of the disease, and yet disappear, and patients being free from murmur have been considered to be free from cardiac complication. I have, in my former lecture, deprecated this as a too hasty conclusion. It may

be well to inquire in the first place what is the probable nature of these transitory or evanescent murmurs, which are by no means uncommon, for they occur, as the statistics of the London Hospital for 1880 and 1881 show, in about 10 per cent. of the cases. Rheumatism is a disease notably attended with anæmia. Is it probable that these bruits are of the nature of those which we have considered to be causally related with anæmia? The evidence collected for me by Dr. Gubbett as to the site of such transient murmurs is, I think, against this view. It is well known that the murmurs heard in connection with anæmia, though sometimes heard at the apex and indicating mitral regurgitation, are far more frequently audible at the base over the site of the pulmonary artery or aorta. Even when heard at the apex, they are usually accompanied by other murmurs at the base. In rheumatism, however, the usual site of the evanescent murmur is the apex. The totals for 1881 show as follows:—Transient murmurs in mitral area, 15; at base and apex, 7; in aortic area, 5; in pulmonary area, 3. It would appear that a murmur which might suggest an anæmic causation is almost confined to a first attack of rheumatism; after two or more attacks no basic transitory murmurs are recorded. Then as regards the transient systolic murmur in the mitral area, we may ask whether it may be due to myocarditis. If so, it does not resemble in associated phenomena the murmur observed in typhoid, &c. The peculiar perturbations of rhythm are not recorded, and it would appear probable that if there be myocarditis, it does not occur in disseminated areas as in typhoid. May it not be that the temporary regurgitation is due to a localised myocarditis developed in the neighbourhood of the swollen valve or inflamed endocardium? Thus, though the swollen valve might not be in itself incompetent, a temporary incompetence would be produced by the impairment of the force of the muscle. As the myocarditis subsided the valve would become again competent, but probably in many instances to present a renewed imperfection when the swelling in the course of time has given rise to fibrous change and consequent retraction. I draw attention to this as a caution in the expression of any opinion that a valve is sound after a murmur developed during rheumatism, even though the murmur be temporary.

(To be continued.)

VACCINATION: ITS PLACE AND POWER. (a).

By THOS. M. DOLAN, L.R.C.P., F.R.C.S.E.,
Physician to the Halifax Infirmary.

AMONGST the many duties which were entrusted to Boards of Guardians, there was no more important and responsible one than that of carrying out the provisions of the Vaccination Acts. When the Legislature imposed this duty upon Boards of Guardians, it did so in the hope that by means of the network of Boards spread over the whole country, the measure would effectually reach the poorer classes of society. The general success of the measure could only be secured by the loyal enforcement of its provisions by means of each local authority; for if one Board neglected, and another enforced the Acts, the action of the one would be neutralised by that of the other. The intention of the Legislature, as thus defined, if carried out, would secure the general and successful administration of the Acts. The Vaccination Acts had thus more than a local interest. The Boards, by the exercise of the compulsory powers of the Act, could compel persons to have their children vaccinated, or in default, could institute legal proceedings which resulted in fine or imprisonment. Under every aspect of the question, a great responsibility rested upon boards of guardians, so that the subject of vaccination was one well worthy of the attention of that conference. Having such authority, it might be expected that guardians of the poor should know something of the history and effects of vaccination; what it is, what it claims to do, what its dangers are, and what safeguards are provided to protect from injurious results. Many objections have been raised against the measure. It was regarded

unfavourably by a number of people, who objected conscientiously on various grounds to the Acts. In his opinion it was wise to consider those objections. They did not shirk inquiry. The majority of the objections raised at the present day had been answered over and over again. Dr. Seaton, in a volume of 500 pages, published in 1868, had exhaustively treated the subject of vaccination, and had completely answered the various objections which had been started up to that time. Opposition or severe criticism was not deprecated. A rigid censorship could only have the effect of stimulating the medical profession to increased carefulness in what was at first sight a very simple surgical operation, but which was in reality a very serious one. He would lay before them a mass of facts, in the hope of convincing them that the Vaccination Acts were worthy of their loyal support. Before proceeding with the subject of vaccination, Dr. Dolan explained the practice of inoculation, which he said many people confused with vaccination. Inoculation was the introduction into the skin of pure small-pox. The practice was introduced into this country from Turkey, in 1717, by Lady Mary Wortley Montagu, wife of the English Ambassador at Constantinople. In one of her letters she wrote that the people "take the small-pox by inoculation by way of diversion in Turkey, just as they take the waters in other countries." Inoculation was suppressed by law in England, as it spread small-pox. Vaccination was the introduction of a clear, bright, transparent liquid called lymph, which was derived from cow-pox. The history of vaccination was one of the most interesting in the record of science, and was inseparably connected with Dr. Jenner. Since Jenner promulgated his doctrine in 1798, no less than 18,744,475 persons had been vaccinated at the expense of the poor rate. Jenner's fundamental doctrine was that cow-pox was a product of the same virus which produced small-pox, so that a person having acquired cow-pox was protected just as if he had gone through an attack of small-pox. Though Jenner was a great man, he was not infallible. He believed that cow-pox was related to the disease called "grease" in the horse. Jenner was in error on that point. Cow-pox was not related to that disease, though the horse did suffer from a disease called horse-pox, which was analogous to cow-pox. The first truth was that cow-pox, horse-pox, and human small-pox were allied to one another, and they had a common origin at some time. Diseases in the lower types of animals were nearer allied to the higher than they supposed. The chief points which it was necessary to grasp were, first, that the cow was liable to a natural disease called vaccinia, from which vaccine or lymph was derived. The vaccine in use at the present day was derived almost in succession from the stock introduced by Jenner. They had Dr. Seaton's authority for that. Secondly, artificial cow-pox might be produced in various ways in the cow. Though there were many methods of introducing cow-pox artificially, one only was adopted, namely, communicating the natural cow-pox found in the cow to other cows or calves, and thus keeping up the supply by natural cow-pox. That was called animal vaccination. At 95 Lamb's Conduit Street, London, animal vaccination was now carried on under the sanction of the Local Government Board, side by side with arm to arm vaccination. The system was introduced to satisfy the doubts, fears, imputations, and prejudices of the public. He had himself used animal vaccine for the past three years with success. Not that he had any doubt as to the efficacy or purity of the lymph he could obtain, but as a concession to the feelings of those who objected to the humanised lymph. He vaccinated his own children with humanised lymph, and the vast majority of medical men—999 out of 1,000—vaccinated their own children. Was it reasonable to imagine that they would expose their own flesh and blood to the risk of blood-poisoning if vaccination were, as it was said to be, such a dangerous measure? Could they suppose that they were so lost to the sense of parental love as to imperil the lives of their own offspring

in order to bolster up a compulsory system of vaccination? If names were of any value, let them put in the scale of reason the action of the medical practitioners of the town, who had vaccinated their children, against the solitary example of one practitioner who would not do so, and ask themselves the question—assuming, as they had a right to assume, that those practitioners had had equal medical education, and equal experience, and were possessed of the same degree of parental love—who were likely to be right, the solitary individual, or the majority? It might be said majorities were not always right. He had yet to learn that minorities were. In supporting this measure the medical profession were acting impolitically, and against their own interest, because they would be able to make more pecuniarily by small-pox than by vaccination. But the profession were acting, as he hoped they would always act, for the good of mankind. What powers, it might be asked, were really claimed for vaccination? Much misconception prevailed upon this point. The view of Jenner was, that duly and efficiently performed vaccination would protect the constitution from subsequent attacks from small-pox, just as much as small-pox itself would. He never expected it would do more, and had believed it would not do less. An attack of small-pox would not give absolute protection against a second attack. The modern view was, that efficiently performed vaccination gave absolute protection to the large majority, and to the minority it modified the course of the disease, so that really the risks of death were lessened, and those disfiguring traces, which were not the least of terrors of small-pox, were not now so frequently met with. There was no subject upon which medical testimony was more unanimous than on that point. Vaccinated persons—children and grown up—had lived in crowded and ill-ventilated dwellings, in which small-pox prevailed; they had occupied the same rooms, slept in the same beds with small-pox cases; mothers had nursed their babies suffering from the disease, and yet they had escaped unscathed.

The next power which was claimed for vaccination was that it modified the course of small-pox in those in whom the protection had not been absolute. Various circumstances exercised more or less influence on the protective powers of vaccination, such as the quality of the vaccine, the age of the individual, personal, hereditary, or family susceptibility, change of climate, frequency and extent of exposure to infection, and intensity of epidemic influence. There was no rule without an exception, and the phenomena of diseases, though they proceeded on uniform lines, were yet liable to be disturbed by influences over some of which they had control and over others of which they were powerless. Amongst the circumstances which influence vaccination, the quality of the vaccination was a factor of importance. There were good and bad vaccinations. The system should not only be infected, but it should be well infected. Careful observation had been made at the Small-pox Hospital in London, which had clearly established that, according to the number of marks on the arm, in that proportion had protection been offered. Statistics were of use in an inquiry of that kind. In the Halifax epidemic of 1871-2 the total number of cases under the author's care at the Halifax workhouse was 115—males 62, females 63. Five died. One hundred and nine had been vaccinated, and six were unvaccinated. Out of the 109 three died, a ratio of 3 per cent.; out of the six two died, a ratio of 32 per cent. In the London epidemic of 1876-9 the total number of small-pox patients treated by the Metropolitan Asylums Board was 15,171. Of that number, 11,412 had been vaccinated, and 3,759 were unvaccinated. The deaths were 2,677. Out of the 11,412 vaccinated persons, 1,008 died; out of the 3,759 unvaccinated persons, 1,669 died. In the one case there was a mortality of 8.8 per cent., in the other of 44.4 per cent. Had vaccination lessened the general mortality from small-pox? There were three periods to be noted—one ending 1840, prior to the enactment of any vaccination laws; one ending 1853, during which vaccination was gratuitously performed; and one

in which they were now living—the era of compulsory vaccination. In the first period vaccination was not general, and in the first period they had not the excellent system of death registration which they now had. If they took certain groups of years, they would be able to arrive at some estimate of the general effect of vaccination in lowering attacks of small-pox. Taking an average of 30 years, previous to the introduction of vaccination, the annual death-rate per million of the population from small-pox was 3,000. From 1838 to 1840, since vaccination became diffused, but before the public provision was made for its gratuitous performance, the rate fell to 770. From 1841 to 1853, when vaccination was gratuitously provided, but not compulsory, the rate fell to 304. From 1854 to 1865 it fell to 202; and from 1865 to 1881 it fell to 201.5. Dr. Guy had put the figures in another way. In ten years ending 1770 small-pox caused 108 deaths per 1,000; in the ten years ending 1860, the deaths were only 11. The natural statistics of other countries gave even more striking illustrations. The author quoted figures from the public returns of Denmark, Sweden, Westphalia, Bohemia, Austria, Silesia, Germany, France, and other countries, in support of his statement. The mere enumeration of figures, however, was not sufficient to enable them to grasp the great saving which had resulted from that beneficent measure. To appreciate the value of vaccination they should know what small-pox was in the natural state. In its natural state small-pox was one of the most loathsome and fatal pestilences that ever afflicted mankind, and it entailed the most distressing consequences in the shape of blindness, deafness, and impaired health. It vied in its fatality with the black death, the plague, the sweating sickness, scurvy, and jail distemper. It prevailed in every part of the world, amongst all ranks of society, and both sexes, and in all seasons. It swept away whole nations. In one instance in the town of Ceara in the Brazil, in a population not exceeding 70,000, no fewer than 40,000 deaths had taken place in 1878-9. Such was small-pox in its uncontrolled or natural state. He claimed for vaccination a place as one of the most beneficent discoveries which had ever been made for the good of humanity, and with justice did he claim for Jenner a niche, not only in the temple of fame, but in the hearts of the people he had benefited. Vaccination was not unattended with danger. The Medical Department of the Privy Council had always recognised that. What were the safeguards? The guardians appointed a medical practitioner who had two qualifications and who was acquainted with the special duties of vaccination, and the Local Government Board gave vaccinators instructions so minute and so carefully drawn up that no mishap could follow if the vaccinator observed them. At the National Vaccine Establishment, London, the most scrupulous care was exercised in the selection and processes required for the preservation of vaccine. The Local Government Board had recognised from the first the great principle that in a country where vaccination was compulsory the duty of the state was to put into the hands of the people lymph or vaccine free from even the suspicion of adulteration. The lymph sent out by the National Vaccine Establishment had been uniformly pure and good. 18,744,475 persons had been vaccinated at the expense of the rates from 1852 to 1880, and at least ten millions more had been vaccinated by private vaccinators, so that it was not surprising if some mishaps had followed, for no surgical operation, however slight, could be performed with perfect freedom from risk. They had expected too much from vaccination, and they had also expected that vaccination would proceed without any disturbance from external or internal influences, such as the sanitary surroundings of the person vaccinated, the hereditary peculiarities of the infant, previous taint of syphilis or scrofula, care and attention on the part of those who had to look after the child—all factors which should be taken into account.

His statistics were those of such men as Drs. Seaton, Simon, Guy, and Marson—all men of unimpeachable

honour, whom the most reckless would not dare to assail, of men who had no interest in falsifying figures, so that any objections to his statistics on that ground could not be entertained. He would state a few of the objections generally raised. It was alleged that vaccination increased the mortality from other diseases. Vaccination did not profess to make mankind immortal; it saved them from small-pox and its sequelæ, and nothing else. One might as well object against saving men from drowning, because they would afterwards die from some other disease. It was alleged that cutaneous or glandular diseases might be invaccinated. Inasmuch as cutaneous and glandular diseases were frequently noticed in children subsequent to vaccination, vaccination was blamed for what was really due to causes inherent in the child. He was not a public vaccinator, but he had vaccinated some thousands of private patients, and he had never seen any cutaneous or glandular disease resulting from vaccination. He had refused to vaccinate the children of fathers whom he had attended for syphilis shortly before their marriage, as he knew that if any cutaneous eruptions developed on the skin of the children after vaccination the vaccination would be blamed and made the scapegoat for their consciences. The danger of transmitting syphilis by vaccination was a very serious one. It might, however, dispel the fears of many when he told them that during the many years in which there had been systematic inspection of public vaccination in England, of the millions who had been vaccinated, in no single case had the Government inspector of vaccinations been able, after the most rigid inquiry, to find a single case of syphilis due to vaccination. That was the statement of Dr. Stevens, chief vaccination inspector. The harmlessness of vaccination, and of every medical or surgical operation was dependent on the skill and care of the medical practitioner. The public were in their hands. The medical man might poison his patient, or in using a lancet might kill his patient. That would happen either from ignorance or carelessness. Pure un-mixed vaccine lymph could not communicate syphilis, even though taken from a syphilitic subject. There were well-attested experiments to prove that. Now that animal vaccination had been introduced, the objection on the ground of syphilis was disposed of, as civilisation had not yet reached the calf or cow, and that disease, which was so rife in great towns and cities, was unknown to the bovine race. The next objection was that erysipelas might follow vaccination. That was undoubtedly true, and in a small proportion of cases erysipelas had followed. Erysipelas might follow any slight surgical operation, and it was a danger against which medical men were on their guard. The next objection had more than a medical bearing. Parents objected to vaccination as an interference with the liberty of the subject. The Briton did not like any infringement of his liberties; he regarded his house as his castle, and his children as his property, and he would not brook any interference with his rights over them. In all countries, for the good and happiness of the greater number, laws were passed which pressed hardly upon individuals. Hundreds of fathers and mothers objected to the shortening of the hours of labour in factories, and he regretted to say there were many who objected to compulsory education. After a painstaking inquiry and examination of witnesses adverse and favourable to vaccination, the Legislature passed the Vaccination Acts for the greater good of the greater number. In 1871 a Select Committee of the House of Commons gave a most patient hearing to those who objected to the Vaccination Acts of 1867; and the evidence must have been most convincing when they pronounced so strongly in favour of the continuance of compulsory vaccination.

The author next alluded to re-vaccination, and the evidence furnished by the complete immunity from small-pox of the nurses at the London Small-pox Hospital in favour of re-vaccination. Dr. Guy had truly said that the history of vaccination was the romance of science. Science had always been a wonder worker, and often a dispenser of rare benefits to mankind. She never shone forth so

brightly, however, in both characters, as when she put it into the mind of Edward Jenner to extract from the neglected gossip of the dairy the means of destroying the most loathsome and fatal pestilence that ever afflicted mankind. The vaccination introduced by Jenner was receiving a new development, and it was impossible to tell at present where it might end. Pasteur, the great French chemist and scientific investigator, was applying the principle of vaccination to the extinction of other diseases. Pasteur, in describing his experiments at the International Congress in London in 1881, said that he called his system vaccination in the hope that science would accept it as homage paid to the merit and to the immense service rendered to humanity by one of the greatest men England had ever produced—the illustrious Jenner. It would be a fortunate day for humanity when science had found a method of combating scarlatina, measles, and typhoid, &c., somewhat similar to that in which they now combated small-pox. He did not hope to convince all present of the value of the Vaccination Acts, but he trusted that the majority would agree with him, that if vaccination were universally and effectually performed, the dangers of small-pox would be quite inconsiderable. The careful were now subjected to danger by the careless. Because small-pox did not always break out in districts where vaccination was imperfectly carried out, certain classes of objectors used that as an argument against vaccination. They knew from experience that miners had exposed their fellow-men to utter ruin and destruction by using a naked light, but no explosion had followed, because fire-damp did not happen to be present in the mine at the time. The miner might use that as an argument against the use of the Davy lamp. The presence of unvaccinated persons in their midst was a danger to society—they were tinder which a spark might inflame, and they must be compelled, in the interests of society, to take those precautionary measures which science, experience, and common sense had declared to be advisable and necessary. They should speak their opinion on that matter with no uncertain sound. The vital interests of the vast majority who complied with the Vaccination Acts should not be endangered by the small band of anti-vaccinators who set the law at defiance. The passive majority should resist the active minority, who were so industrious in spreading about tracts, leaflets, &c., full of inaccuracies. Some of the millions whose children had been vaccinated should testify that their children had not suffered from vaccination. There were times and circumstances when to be silent was to connive. There was a common-sense view of that question. What do the risks really amount to? Even granted that a number of deaths from erysipelas had taken place as the result of vaccination, what proportion did they bear to the millions who had been vaccinated? They were homœopathic, they were so infinitesimal. Dr. George Harley, F.R.S., had very well expressed the common-sense views on that question. The principle of vaccination, he said, was strongly and soundly scientific, from the fact of its being based upon the philosophical maxim that it is always best to accept the lesser of two evils, and voluntarily submit to be the victim of a mild and non-fatal disease such as vaccine, rather than run the risk of accidentally acquiring in all cases a loathsome, and so frequently a fatal form of disease—small-pox. What were the lessons which were taught by the knowledge of the facts of vaccination? It seemed to him conclusive that not only should the Acts be enforced, but that the quality of the vaccination should be improved, so that it might become as Jenner desired it to be, more effectual. In private practice medical men had to defer very much to the prejudice of parents, and in consequence of that any sort of vaccinal effect upon the arm was regarded as successful vaccination. Mr. Ernest Hart suggested that the certificate of successful vaccination should be given, not by the vaccinator, but by the medical officer of health. Dr. Seaton was also of opinion that some such system of inspection should be adopted. It was the dream and

ambition of Jenner that small-pox might be completely stamped out by vaccination, and had vaccination been truly and effectually performed, they would not have had the serious epidemics that had occurred since his time. He trusted they would take those lessons to their hearts, and that, warned by the experience of the past, they would assist the Local Government Boards by a loyal enforcement of the Vaccination Acts. Recognising the power of vaccination as a protective against small-pox, they would give it its proper place, and discourage agitation against those wise and beneficent measures.

Clinical Records.

CASE OF PERICARDITIS WITH EFFUSION—ALBUMINURIA—TREATMENT—PARTIAL RECOVERY—RELAPSE—DEATH.

Reported by JOHN W. MARTIN, M.D.,
Sheffield.

EDWARD BOURK, *æt.* 50, boatman, employed on a lighter, plying on the river Suir, residing in Portlawn, came under my notice on August 16th, 1872. Some weeks before my seeing him he had got a severe wetting, which was followed almost immediately by a sense of oppression about the chest, and dyspnoea, which grew daily worse. Previous to this wetting, he had always been a strong, healthy man, and also, had always been a fairly temperate man. Never had any symptoms of articular rheumatism. He had no cough or actual pain. The lungs were normal. The slightest exertion exhausted him and compelled him to stop and rest. He could not walk fifty yards without doing so. Three days before coming to me, he noticed his feet swelling, and occasional, but not constant, slight puffing of the face. He had no pain in the back, and the abdomen presented no symptoms of ascites. He was passing urine freely, which, on examination, showed merely traces of albumen. His tongue was clean, and the bowels fairly regular, but tending towards being confined. Examining the heart, I found the area of cardiac dulness enlarged, measuring 4 × 4 inches in diameter; the superior margin being on a level with the lower border of the third rib on the left side, and the external margin being a little outside the left nipple line. The heart's impulse was greatly weakened, and diffused over a large area; there was displacement of the apex beat. The first sound of the heart was faintly heard over the apex, and greatly shortened. The second sound was also weakened. Towards the base a loud, rasping, friction-murmur was heard, diffused over a wide area, synchronous with the ventricular systole. I regret to say I omitted to note the condition of the pulse.

In spite of the presence of the albumen in the urine, I applied a blister 4 × 4 inches over the area of dulness, and left it on for eight hours; and ordered him the following mixture:—

R. Potass. iodidi, ℥ij;
Tr. aconiti, ʒss.;
Tr. aurantii, ʒij;
Syrupi, ʒss.;
Aq. ad ʒviij.

M. ʒj. to be taken three times a day.

August 20th, 1872.—The blister had taken good effect. The chest symptoms were relieved, but the œdema in the legs had increased, and extended into the abdomen, where there was a considerable amount of ascites. The bowels were confined. He was still passing water freely, and of the same character as before. I ordered him three powders.

R. Pulv. jalapi co., ʒss.;
Hyd. c. cretâ, gr. iv.;
Pulv. zingib., ʒj.

M. One such powder to be taken each night, until the three were finished.

27th.—The bowels had been freely acted upon. The ascites and œdema of the lower extremities were almost gone. The heart symptoms were much relieved. The area of dulness was diminished to 3 × 3 inches. The impulse was stronger. A loud friction-murmur was heard at the apex synchronous with the systole; it was diffused over a large extent of the chest wall. The basal-murmur was still the

same. The point of impulse was felt more towards the left side. He was no longer troubled with dyspnoea, and, indeed, felt so much better that, against my wishes, and owing to the poor circumstances in which he lived, rendering work necessary, he returned to his employment.

Sept. 14th.—He had caught a fresh cold. All his former symptoms returned. Being unable to support himself, and without resources, he was compelled to enter the Union hospital, where he remained until his death, which took place on the 20th of October, 1872.

I regret to say that I have not full notes of this case, but it is another example of the frequent occurrence of pericarditis with effusion. Some weeks having elapsed before I saw him, it would be impossible to say whether the albuminuria had existed from the first, but from the history of the case I am inclined to regard it as a sequence. Undoubtedly, the blister gave relief to the chest symptoms, but, probably, it may have had something to do with the increased oedema in the lower extremities, and the appearance of ascites.

I think the absence of change in the amount of albumen in the water is a curious and not easily explained point. I should certainly carefully consider the risks again, before I applied a blister, in the presence of albuminuria; but, at the same time, there are circumstances, under which, I would take the risk, and apply the blister.

The results of treatment up to August 27th were very satisfactory, and I have no doubt, that the man would have made a good recovery, could he have abstained from work for some time longer, and taken care of himself.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 26TH, 1882.

The President, Dr. ANDREW CLARK, F.R.C.P., in the chair.

Dr. LONGHURST

ON THE ACTIVITY OF THE INFECTIVE POWER OF THE POISON OF SCARLET FEVER DURING THE PRE-ERUPTIVE STAGE OF THE DISEASE.

In a short paper on the infection of scarlet fever in the *Lancet* of July, 1877, I expressed a belief that the period of greatest activity of the fever-poison was in the early stage of the disease. Extended observation has strengthened such belief, and it is borne out in the cases reported, which seem to encourage a line of investigation in connection with the study of acute specific diseases advocated by the late Dr. Murchison in a paper on the period of incubation of scarlet fever, and the probability that they may be transmitted even during the stage of incubation. Case 1 supports such view, and forcibly demonstrates that the fever poison is not absorbed by, nor developed in, all persons with the same rapidity and activity, and that possibly even during the stage of incubation the poison may be passed on from one member of a family to another, the latest case having little, if any, direct relation to the first, but being due to the further development of the poison through fresh systems. Cases 2, 3, and 4 all point to the activity of the fever-poison in the very earliest stage; whilst Case 4 is especially interesting as proving that the long isolation and confinement still enforced by some is not always necessary. It is, I think, most important that a belief in the activity of the infective power of the fever-poison during the very earliest stage, possibly, also, during that of incubation, should be generally accepted; for then, instead of risking the spread of the disease by scattering at once the members of a family, thus forming new and fresh centres of infection, ought we not rather to be content by isolating the sufferer in his own home, or by removal to hospital, according to circumstances, and by rigidly adopting all sanitary precautions? If, also, we admit the activity of the fever-poison to be in the earliest stage rather than during the stage of desquamation, as still held by some, then, we shall feel that the long period of isolation and confinement of two or three months, as still in the opinion of many deemed necessary, may be safely shortened to the very great relief of both the sufferer and his family.

Dr. BROADBENT was of opinion that further evidence than that offered would be required to substantiate the theory

advanced, as to infectiousness of scarlet fever in the pre-eruptive stage; only vague statements had been submitted in proof of the point raised in the paper, and it was highly probable that all the members of the family had in reality been exposed to contagion in the first instance. He had seen cases in which children had slept in the same bed with patients suffering from scarlet fever, and who, being separated on the appearance of the rash, had yet escaped all infection. That they were susceptible to it, however, was shown by their contracting the disease subsequently from an entirely different source. Measles and mumps were undoubtedly contagious in the early stage; but, he contended, there was no experience of a like kind in respect to scarlet fever. He agreed that it was unwise to send away the members of a family, one of whom had contracted the disease, for at the Fever Hospital it was occasionally found that despite all precautions in the way of disinfecting the persons who left it, these nevertheless did sometimes carry away infection to their families.

Dr. B. O'CONNOR suggested the advisability of investigating food supplies, viz., milk, toffees, &c., as carriers of the infection.

Dr. G. SMITH instanced the case of a child, an inmate of an orphan's home in the country, and who, on returning from a visit to London, was found to present the rash of scarlet fever. The children nursed by the same attendant who had charge of the case were next day found to be affected with the fever, thus demonstrating its incubation within twenty-four hours. He would suggest rapidity of incubation as a possible explanation of the results recorded by Dr. Longhurst. At the Fever Hospital seventy-five hours was regarded as the average time in which the disease might be expected to appear. He did not consider the fever was infectious in its pre-eruptive stage.

Dr. GLOVER thought it most desirable that the Society should show that it did not endorse Dr. Longhurst's opinions, for the fever was certainly infectious in the latter stages of the disease.

Mr. F. R. JESSETT agreed that the peeling stage of scarlet fever was infectious. He instanced a case in which a child caught the fever through wearing clothes left off by its sister two years previously, and from the patient so infected a whole village contracted the disease. In another case a calico ball was traced to be the source of origin of an epidemic whereby from thirty to forty children were attacked with measles through the presence of one guest so affected.

Dr. EASTES said that on one occasion, when he was himself suffering from scarlet fever, his brother came to see him from Epsom School, and was subsequently attacked by the disease. But no other of the fourteen boys who occupied the same dormitory with him suffered, although he was not removed elsewhere till after the appearance of a rash, thus showing the non-infectiousness of the pre-eruptive stage. Dr. Eastes cited also another case of a somewhat similar kind.

Mr. BLACK narrated a case proving the infectiousness of measles in the catarrhal stage.

Dr. DYCE DUCKWORTH urged the necessity of adopting, as a universal rule, that scarlet fever patients should be confined between the blankets for at least three weeks, and to their room for eight days longer. Thereby the number of renal complications would be much reduced, and great benefit generally experienced.

The PRESIDENT thought Dr. Longhurst had failed to maintain the position he had taken up, to do which he must show that no other cause of infection could have been at work in the cases instanced by him. His own experience, said Dr. Clark, led him to advise confinement for six weeks, under which time no perfect safety could be anticipated. Some years ago, while scarlet fever was present in his own house, he received an invitation to Scotland, and somewhat unwillingly he yielded to persuasion to accept it on the expiration of the six weeks he prescribed. Within a week of his arrival in the Scotch village, which had been hitherto free from scarlet fever, the disease appeared among the inhabitants. [Dr. Clark did not say he had imported the fever on this occasion.]

Dr. LONGHURST replied that he thought the subject was one demanding investigation, and hence he had brought it before the Society. He had been unable to trace any source of infection such as had been suggested, and he could not resign his opinion that the disease was infectious

in its early stages, and more so than during desquamation. As regarded removal of patients, he insisted that less danger attached to them than to their surroundings, clothes, &c.; and he believed that concentration of the disease in hospitals might influence its spread in a way not otherwise probable.

ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.—FRIDAY, JAN. 11.

Mr. J. K. BARTON, President of the College of Surgeons, in the Chair.

Mr. WM. STOKES, Sectional Secretary, and Mr. WM. THOMSON, General Secretary, were in attendance.

EXHIBITION OF SPECIMENS.

Specimens by card were exhibited by Messrs. Wheeler (Vice-President), Thomson, and Stokes; and living specimens by Messrs. Benson, Swan, Wheeler (Vice-President), and Croly.

ANÆSTHETICS IN CERTAIN SURGICAL OPERATIONS.

Dr. FITZGIBBON read a paper advocating the use of anæsthetics in surgical operations upon the mouth, anus, and rectum, and especially in operations for the removal of internal hæmorrhoids. The anæsthetic he recommended was bichloride of methylene, which he had largely used in the foregoing operations, employing Junker's inhaler.

The PRESIDENT corroborated Dr. FitzGibbon's statement with regard to the facility of exploring the rectum under anæsthetics.

Mr. HAMILTON pointed out that rectal surgery had for many years past undergone great modification. He alluded to a paper of his, published several years ago, recognising the advantage of anæsthetics in the treatment of hæmorrhoids. Anæsthetics were, he considered, more adapted to the rational and scientific treatment of rectal diseases than any other department of surgery. Indeed, he did not think that any conscientious surgeon would operate without anæsthetics, which had the advantage in addition of overcoming the repugnance that many persons had to such physical examination.

Mr. THOMSON observed that from the time he was a student in the Richmond Hospital almost all rectal operations had been performed under the influence of anæsthetics, except in cases where there was some special contra-indication. His experience of ether as an anæsthetic was so favourable that he did not see any reason to substitute bichloride of methylene for it, especially as it was not as safe as ether.

Mr. ORMSBY distinctly preferred ether, and pointed out that statistics were against the use of bichloride of methylene and chloroform. He doubted the propriety of advocating the use of anæsthetics in all cases requiring rectal operations.

Mr. PRATT stated that his experience of bichloride of methylene was very favourable. Its action was much more rapid than that of ether, and the required quantity used much less, especially in protracted operations.

Mr. MYLES asked Dr. FitzGibbon to state the grounds upon which he claimed for bichloride of methylene advantages over ether in operations on the tongue.

The VICE-PRESIDENT (Mr. Wheeler) endorsed all that Dr. FitzGibbon had said in reference to the advantages derived from the use of bichloride of methylene. He thought that the length of time patients remained intoxicated after the use of ether was a disadvantage which was got rid of by the use of bichloride of methylene, and that there was less liability to sickness after the latter. In cleft palate operations, especially in very young children, the use of anæsthetics was indicated.

Dr. MACSWINEY alluded to the late Prof. Morgan's researches on anæsthetics, and asked Mr. Stokes what anæsthetic he had used in the case of excision of the superior maxilla exhibited previous to the meeting.

Mr. W. STOKES observed that in the case Dr. MacSwiney alluded to ether was used, and he preferred it to any known anæsthetic.

Dr. KILGARRIFF also gave a preference to ether, and enumerated various important operations about the mouth in which he had employed it with success.

Dr. FITZGIBBON replied, emphasising the alleged advantages of bichloride of methylene over ether and chloroform, particularly in operations about the rectum and the mouth.

TREPHING IN MASTOID AND TYMPANIC DISEASE.

The VICE-PRESIDENT (Mr. Wheeler) read a paper on trephining in mastoid and tympanic disease. He related the causes of purulent discharges from the ear, and the necessity for early trephining in diseases of the osseous structures, if not yielding to other treatment within a reasonable time. He recorded the last two cases he operated on, the first that of an old man æt. 70 (who was present), and the second that of a patient æt. 41, who suffered from acute inflammation of the mastoid process. Both made good recoveries. Statistics which he quoted showed that nearly all the cases left to nature or expectant treatment died. Having enumerated the various channels through which purulent discharge found its way to the cranium, he advocated trephining in that situation where the mastoid cells and tympanum would be opened and the dura mater exposed, namely, anterior to a line which divides the mastoid process vertically, which would avoid the lateral sinus and the lower border of the trephen lobe on a level with the external auditory meatus.

Mr. BENSON inquired what treatment previous to operation had been adopted by Mr. Wheeler, mentioning that Mr. Pollock and other authorities did not despair of effecting cures in such cases even when there was caries of the mastoid cells. He also asked Mr. Wheeler to state on what grounds he had arrived at the conclusion he did, which was not proved to be accurate.

Mr. DOYLE mentioned cases of mastoid disease that had been successfully treated by making an incision on the mastoid process.

Dr. HENRY KENNEDY stated that in his experience such cases as had been detailed were not permanently benefited by incising the mastoid process.

Mr. THOMSON asked whether Mr. Wheeler had adopted any other treatment than what he had stated in his paper, and also whether in all cases of otorrhœa with tenderness over the mastoid process he would at once recommend trephining.

Dr. BENNETT pointed out that Mr. Wheeler had described his treatment only in cases in which, while there was otorrhœa, there was manifestly disease in the neighbourhood of the mastoid process capable of being detected. There were a number of cases where the bone was diseased, and where the disease was entirely remote from the mastoid process.

Mr. WHEELER, in reply, said that the previous treatment in the case of the younger patient alluded to by Mr. Benson was simply syringing the ear. There was evidently disease of the bone. He had not stated they were to trephine without adopting other means, but he had mentioned that if the disease lasted any length of time he would trephine, even in the absence of osseous disease. He alluded to the statistics of the operation, which showed that trephining was not, comparatively speaking, a serious operation. He had seen one where excellent results had been obtained by incising the mastoid process, but in these there was no disease of the cells. Dr. Bennett had asked if he would trephine in all cases, and if there was a piece of bone diseased at the apex of the petrous portion of the temporal bone whether there would be any possibility of doing good. He (Mr. Wheeler) doubted if diseased bone could be thus diagnosed; but if the person had cerebral symptoms and running from the ear, he would be induced to trephine. The operation was not done often enough.

The Section adjourned.

MEDICAL SECTION.—FRIDAY, JANUARY 19TH.

Dr. WILLIAM MOORE, President of the King and Queen's College of Physicians, in the Chair.

Dr. A. N. MONTGOMERY, Sectional Secretary, and Mr. W. THOMPSON, General Secretary, were in attendance.

LIVING SPECIMENS.

Mr. A. H. BENSON exhibited a case of hard chancre on the upper eye-lid; and Dr. J. MAGEE FINNY, a peculiar case of vesiculo-tubercular disease of the skin of eighteen years' standing.

SPECIMENS EXHIBITED BY CARD.

Dr. A. W. FOOT exhibited drawings of facial chromidrosis; Dr. H. KENNEDY, urinary calculus; Dr. C. I. NIXON, aneurism of arch of aorta obliterating arteria innominata; Dr. H. C. TWEEDY, heart showing vegetations on the mitral and aortic valves; and Dr. F. J. B. QUINLAN (1) bacillus of tubercle in sputum, and (2) bacillus of tubercle in lung tissue.

EMPHYEMA, WITH NOTES ON ANTISEPTIC FLUIDS AND DRAINAGE TUBES.

Dr. RICHARD A. HAYES first read a paper on a case of empyema treated by the radical method, with notes on some antiseptic fluids employed. After some observations pointing out especially the great danger of producing general anæsthesia in cases of intended operation on large fluid effusions in the thoracic cavities, he mentioned the particulars of the case. A man, æt. 22, was the subject of right empyema of eighteen months' standing, with severe hectic and washing. On his admission to Stevens' Hospital, the pus was thrice removed by aspiration, and the cavity washed out with carbolic solution, without effecting a cure. An intercostal incision was then made, and a large canula introduced, the pus draining away into pads of oakum placed over the opening, and the cavity washed out daily with antiseptic solution, by means of an elastic catheter. The case progressed favourably, with the exception of a few complicating circumstances, and the patient was ultimately discharged, and went to the country, a sinus only remaining unhealed. During the treatment of the case, the following washes were used:—1 per cent. oil eucalyptus, gr. 2, ℥i., or less than ½ per cent. carbolic acid; 2 per cent. boracic acid; and 2 per cent. salicylic acid. A careful record of the morning and evening temperatures having been kept, the results obtained from the use of the different antiseptics were as follows:—Oil of eucalyptus (1 per cent.), morning temperature, 98·3° F.; evening temperature, 100·4° F. Salicylic acid (1 per cent.), morning temperature, 98·3° F.; evening temperature, 99·5° F. Boracic acid (2 per cent.), morning temperature, 98·2° F.; evening temperature, 99·4° F. Carbolic acid (½ per cent.), morning temperature, 97·8° F.; evening temperature, 98·7° F. The foregoing temperatures are averages, the periods of observation being carefully selected so as to be free from complicating influences which might affect the fever curve. During the entire of the later stages of the case, carbolic acid wash was used, and the temperatures were uniformly identical with the result of observations in the early stages. The results, therefore, show a marked advantage, as regards the hectic, obtained by the use of an exceedingly dilute solution of carbolic acid. That the carbolic acid had this distinct effect was proved by a trial irrigation of pure water, an even temperature of 100° F. following its use.

Dr. PURSER then described a case of left empyema. The patient was a ship's steward, æt. 30. The disease was at first latent, but after nine months he was admitted into hospital, when he was tapped, and subsequently a drainage tube inserted. His condition continued satisfactory for some months, when severe fever supervened, at first of a hectic character, but soon becoming continuous. Death ensued about three weeks from the commencement of the febrile symptoms. The compressed lung was found to contain air, and to have maintained its vesicular structure unimpaired. The cavity of the left pleura was much diminished. There were three wedged-shaped emboli patches in the spleen which were softened and purulent. There were no other evidences of pyæmia. Dr. Purser directed attention to (1) the prolonged latency of the disease, and to the slight distress, notwithstanding the compression of the lung and the displacement of the heart, which beat in the right axilla; (2) the advantages and disadvantages of different kinds of drainage tubes in facilitating discharge and preventing putrefaction; (3) the aseptic fever, in the sense of Volkmann and Genzmer, from which the patient suffered at intervals, as contrasted with the septic fever from which he died; and (4) the apparently slight injury done to the lung by the prolonged compression from the effusion.

Dr. BENNETT called attention to the risk of injecting the pleural cavity at an early stage when fever and dyspnoea were present. He advocated a local anæsthetic and the use of the spray in the radical treatment of empyema.

Dr. FINNY corroborated Dr. Purser's statement as to the

entire absence of fœtidity of the discharge during the time the patient was under his care, as well as at the post-mortem examination. Three weeks before death—the initial period of the fever—much pain was complained of in the left hypochondria, and marked the occurrence of the emboli infarctions of the spleen. Fœtidity of the pus was not induced by the use of a simple rubber tube unprotected by any antiseptic; and it was a question for consideration if a period did not arise in the course of such cases when antiseptics might with safety be dispensed with.

Dr. C. NIXON advocated tapping in cases of empyema instead of at once employing the radical treatment. He detailed a case in which the latter operation was performed without the spray, and as the fluid next day became fœtid, he washed out the cavity with good results.

Dr. W. G. SMITH disputed Dr. Hayes' conclusions as to the advisability of washing out the pleura with antiseptics, basing his opinion on the ground that the periods of trial by Dr. Hayes were too short, and that fluctuations of temperature in cases of empyema were common.

Mr. EDWARD HAMILTON corroborated Dr. Hayes' view on the advantage of washing out the pleura with carbolic lotion, and referred to the vicarious expectoration of pus in cases of empyema as advocated by the late Dr. Græne.

Dr. HAYES, in reply, said he was fully cognisant of the danger of using injections, but that the object he had in view was to bring about a healthy condition of the pus-secreting pleura, and that the lowering of the temperature in his case was directly due to the use of carbolic acid.

Dr. PURSER considered that the only circumstance which justified washing out the pleura was where the discharge was fœtid and continued fœtid for some time.

The Section then adjourned.

Germany.

[FROM OUR SPECIAL CORRESPONDENT.]

GAMBETTA'S WOUND.

As very contradictory statements have been published regarding the nature of the late M. Gambetta's wound, and the mode in which the news was first published, it may not be uninteresting to notice the account sent to the leading Vienna medical journal, the *Wiener Allgemeine Medic. Zeitung*, by its Paris correspondent, M. RUSSEL, not only because this account differs somewhat from those generally received, but also for the reason that an official narrative has lately been published in the *Gazette Hebdomadaire*, in which there appear to be important omissions—that is, supposing M. Roussel's to be correct. It appears that Gambetta had sent his son, who was also the son of a Madame Léonie L—, to Germany against his mother's will. Madame Léonie's husband had died, so that great statesman was free to enter into a legal matrimonial alliance with the mother of his son. This, however, he declined to do. On the 26th of November Gambetta had an exciting interview with the lady, who eventually drew a pistol, and threatened the man whom she was afraid of losing. "He sat upright, and held out his right hand in order to protect himself. A shot resounded, and a pistol-ball struck the thumb between the abductor brevis and flexor pollicis muscles, glided under the skin towards the elbow, where a narrow wound (*Haarseilwunde*) was inflicted, and finally entered the abdominal parietes in the right hypochondria. The ball, fired with but little projectile power, had so far lost its impetus in traversing the forearm and the numerous layers of clothing, that it remained embedded in the abundant adipose tissue of the anterior abdominal wall, and did not penetrate the peritoneum." The bullet was not extracted from the fatty tissues that surrounded it without some difficulty.

"It was given out to the public that Gambetta in handling a

pistol had wounded himself in the forearm; the abdominal wound, and the fact that the shot came from a strange hand, were carefully concealed from the world."

The surgeons were hopeful, and, at the same time, timorous. The illustrious patient died, or, to put it in M. Roussel's own words, "Thus, the Inevitable took place, and, not a little contributed thereto that the wounded man was named Gambetta."

It is not a matter for wonder that the medical attendants should feel their responsibility keenly. Gambetta was no ordinary patient, and the medical attendants were not practising with that complete control over everything and every individual that ought to go hand in hand with the responsibility. They were, moreover, practising as it were on a stage with the eyes of all France upon them, and under the circumstances we should not be disposed to judge them harshly if their sense of responsibility did lead them to abstain from that active treatment that some have thought the case demanded.

Mons. Roussel brings out the difficulties of the attending physicians clearly enough, although he perhaps at the same time speaks as one to whom they were not a personal matter. Had they been so his criticism might have been somewhat different. He says: "The responsibility of physicians is known to be the greater in proportion to the high social position of the patient. For which reason the physicians first called in wished to diminish the individual amount of it by dividing it amongst ten or twelve persons. In such cases, however, the patient is not benefited, but rather the contrary, as no one stirs himself up to a decided step, no one carries out an operation, in consequence of which he might be publicly accused in case it failed to serve the patient. If Gambetta had been a wounded labourer simply, brought into hospital, placed under the charge of a single surgeon, he would probably have recovered. He would then have been compelled to follow the directions of his physician; he would have been obliged to submit to nursing treatment or operation without a voice in the matter. Now, however, the patient is dead, perhaps simply on account of the reasons that rendered the treatment difficult—that he was Gambetta, and that he was treated by a dozen medical authorities from Paris."

Special.

FAVOURITISM IN THE INDIAN MEDICAL SERVICE.

THE following remarks by the Committee of the Indian Medical Service Defence Fund upon the recent promotion of Brigade-Surgeon W. Walker, M.D., to the rank of Surgeon-General, and its effects upon the senior members of the Bengal Medical Service, have been sent to us for publication:—

"The promotion which has just been gazetted is a most flagrant violation of the promise virtually made by the Indian Government. In the Service Gradation List, Dr. Walker stood junior to no less than twelve Brigade Surgeons, men of marked ability, and all possessing professional experience far superior to his own. For nearly 28 years Dr. Walker has been upon civil employ, and that, too, not of a professional, but distinctly of a non-professional nature; he has not, like the majority of his brother officers in the Civil Department, been in charge of large Civil Stations, but has held throughout such appointments as Superintendent of the Government Printing Press, Superintendent of a Central Jail, and the Inspectorship of Prisons—offices the duties of which he has undoubtedly most ably

discharged, but which can scarcely be looked upon as calculated to fit him for the administrative charge of an extensive and important Provincial Medical Staff, and for the position of Chief Adviser of the Provincial Government in all professional matters. Not only, however, has Dr. Walker been promoted over the heads of men of his own rank in the Service, but, as the appointment to which he has been gazetted carries with it the local rank of Surgeon-General, and a rate of pay higher than that attached to ordinary Deputy Surgeon-Generalships, namely, Rs. 2,250 per mensem, instead of Rs. 1,800, he, practically, also supersedes no less than seven Deputy Surgeons-General who are his seniors in the Service, and a glance at the names of the men thus passed over will suffice to prove that the supersession is a most unjust and unmerited one. By G. G. O. No. 575 of 1880, officers of the Indian Medical Service employed on civil duties have, from that date almost to the present time, been required to complete six months' service with a native regiment, within 3 years of the period of promotion, before they could be promoted permanently to the administrative grade, and this rule has been rigidly enforced to the serious detriment of many officers of standing and experience, and even to the absolute loss of promotion to at least two officers in the Presidency of Madras, and the serious retardation of that of a third, who was passed over by a junior while doing this six months' duty. This rule, as far as regards the administrative medical charge of a province, has just been annulled, and will not apply to Dr. Walker, although to ordinary minds it would appear that the nature of the appointments he has held throughout his career would, if anything could, justify its application in his case.

"It has always been the main object of the Committee to represent to the proper authorities, in a temperate and truthful spirit, what they believed to be real grievances. In doing so they hoped to secure, and for a time did secure, the co-operation of Her Majesty's Secretary of State, as the correspondence they have had with the India Office from time to time distinctly shows. Lord Hartington, however, has recently decided that the reception of any further communication from the Committee would neither be 'to the advantage of the public service, or conducive to the interests of discipline:' a view, however, which the Committee venture to think is scarcely a tenable one. A willingness on the part of Government to accept and seriously consider any temperately worded representation of grievances, submitted by individuals in a position to know of their existence, and supported by an accurate statement of facts, could only serve to strengthen the feelings of allegiance which the members of a service of British gentlemen naturally feel towards the Government they serve; whilst the perpetuation, though through ignorance, of a system of favouritism, and the repetition of grave acts of injustice, must tend to engender, even in the most loyal minds, some feelings at least of soreness and injustice, and to inaugurate a condition of chronic discontent.

"The recent changes in the Indian Medical Service have unquestionably inflicted serious injuries upon the prospects of many of the senior members of the Service, especially in the form of retardation, or even absolute loss of promotion; who can fail to see that any honest attempt on the part of the Government to afford some compensation for these injuries would be practically and morally a move in the right direction? It is with the hope that men of influence may be induced to effectively urge these views upon the Government, and thus save the Indian Medical Service from discontent and deterioration, that the Committee venture once more to submit these matters for the criticism and opinion of the profession and the public."

 Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.
 SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hautefeuille, Paris—post free in advance, £1 3s. 6d. per annum.
 SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Philadelphia, by Dr. BRINTON, post free in advance, 5½ dollars (£1 3s. 6d.) per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order.

The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JANUARY 31, 1883.

COLLECTIVE INVESTIGATION OF DISEASE.

EVERY practitioner of medicine who is in any way gifted with a capacity for reflection has frequently regretted the immeasurable waste of opportunities for extending the realm of our scientific knowledge of disease, which he and others situated like himself are unwillingly compelled to participate in. To every intelligent surgeon or physician, each day's experience brings conviction of the valuable nature of such information as can be derived from studying “little things,” trifles almost unnoticeable, but which in aggregate importance will bear comparison with discoveries and inventions that influence the method and material of practical medicine. But keenly conscious though he may be of the shortcomings he is compelled to register against himself, he knows it would be worse than useless to essay alone and unaided the collection of his personal observations; inasmuch as, though they might possess conspicuous value for himself, yet as isolated fragments of investigation they would be in the smallest degree, if at all, useful as an engine for the common advancement of his profession. Hence we find that individual efforts at research are invariably confined to attempts in illustration of single principles or accepted truths; in no wise are they devoted to the comparative study or demonstration of what may be termed “associated phenomena.” They never pretend either to recount or explain the meaning of the trifling details which arise to give individuality to every case of even trivial illness; but their first and only aim is in the

direction of whole presentation of a case, or an operation, or a theory, apart from and independently of every minor element of personal character.

To a certain extent there is a general, tacit admission of this truth to be found in every reported case, where a few lines are devoted to elucidating the history, family and personal, of the patient in question. By an unexplained but undenied sophism this is taken to be the apology of the observer for a common ignorance which he shares as one of many; and to the recognition of the facts that scientific medicine is woefully wanting in a primary element of successful discovery and treatment, we may be allowed to attribute the initiation of a movement designed to fulfil what has long been wished for, but hitherto has not been attempted for want of successful combination in research.

This movement has very properly been commenced under the auspices and with the assistance, pecuniary and organised, of the National Association of Medical Practitioners; and under the title of “Collective Investigation of Disease,” it will henceforth be carried on to the advantage, it may be hoped, both of the science of medicine and of the public, in whose behalf the progress of scientific medicine is held to be a first consideration by members of our profession.

We take it the objects held in view by the promoters of collective investigation are mainly two—viz. (1) to associate together in one common research the whole of the medical profession, or at least all those members of it who are disposed to engage in intelligent study of the phenomena of disease; and (2) to base on the accumulated information thus collected an improved and rational system of medicine. It may be of course that this view includes a somewhat over-high estimate of the intentions properly assignable to the committee appointed to conduct the work of the movement, but at any rate it is no more than ought to be expected as its outcome. The plan at present adopted is to draw up memoranda on the several subjects for inquiry, and to issue with them cards of questions to be answered, a plan which is to a certain extent estimable, but which, we can hardly agree with Sir William Gull “leaves nothing to be desired.” It may even be urged that it falls considerably short of all requirements, inasmuch as it leaves too limited a scope for individual work, and limits in too arbitrary a fashion the extent to which the personal element may advantageously be introduced by those performing the task of “answering.” The plan, however, may safely be accepted as likely to bear a rich and immediate fruit in at least stimulating a line of inquiry, which, for reasons we have given above, has never yet been profitably indulged in.

The most important feature in connection with the movement so far is, unquestionably, the hearty support and encouragement extended to it by the authorities best able to estimate the probabilities to which it opens the door; and at a recent meeting of the Metropolitan Counties Branch of the British Medical Association, Sir Wm. Gull and Sir Jas. Paget showed the practical nature of their sympathy with collective investigation by delivering each an address directly approving the scheme, and indicating the directions which their experience suggested as advisable

for efforts to be applied in. Sir Wm. Gull's advocacy of the cause he attended to espouse is of the most unhesitating character, and in a lengthy speech he successfully illustrated how the combined series of observations may well lead to achievements of incalculable importance. It is in the fact that the movement secures the registration of innumerable separate observations on details of apparently minor, but really of great, significance in the progress of common diseases, that the most instructive results are likely to be forthcoming; for it is chiefly the aggregate of lesser changes, signs, and symptoms that affect the progress of a disease, while it is only the grosser and commonly invariable elements of diagnosis that form the stock of everybody's knowledge. Moreover, it is the general practitioner who, above all, possesses the opportunities for remarking and registering such lesser indications of abnormal conditions, for it is his province to see the beginnings of disease rather than that of the hospital physician, to whom the confirmed invalid alone, as a rule, applies for relief. We therefore fully agree with Sir Wm. Gull that the value of the movement will greatly consist in the stimulus it will give to practising members of the profession at home and abroad to "assist in the inquiry as to the origin of diseases—their early symptoms; their mode of spreading in families; their combinations; the causes of their intensity; their modifications in individuals; in families; their occurrence according to time of year; locality; sanitary conditions; occupations; and many other circumstances, some as yet but dimly understood, and others not yet suspected." And it is impossible not to feel convinced also if the truth contained in the remark made by the same authority, to the effect that "Having passed many years in hospital and private practice, he had come to see that experience gained in the latter is necessary for the correction of that acquired in the former, especially as helping towards a truer pathology." And in the same connection the eloquent though brief address of Sir Jas. Paget rings out a trumpet note of warning against the false superiority of would-be autocratic authority in disease. He observed, "If I may impute a fault to those who are admirable in all the ordinary work of life, I would suggest how large a quantity of knowledge lies scattered and lost to the scientific world in the charge of those who are in large practice, and *who record nothing*." The words we have italicised form in our opinion the strongest argument that can be adduced in favour of any movement which proposes to utilise such inexhaustible stores of information as lie buried uselessly in the treasure-house of experience gathered up by busy general practitioners. But it should nevertheless be borne well in mind that Sir William Gull's advice is not a mere expression of opinion; it is absolutely essential for the movement to be successful that its *intellectual organisation* shall be as far as possible faultless. *Numbers* alone will not suffice; and it is satisfactory to be able to add that, so far, admirable intelligence and consideration have been shown in the arrangements for carrying out the objects held in view.

The collective investigation movement is fairly started; its success must be ensured by hearty co-operation on the part of every practitioner interested in advancing the present knowledge of scientific medicine.

THE NOTIFICATIONISTS AND THE PROFESSION.

THE arrogant and offensive language of Mr. Michael, Q.C., and Dr. Littlejohn, of Edinburgh, at the Social Science Congress, at Nottingham, and wherever else they have appeared as champions of the compulsianist cause, will have prepared the profession for any further ebullition of ill-manners of which either of these gentlemen might be guilty. No surprise will, therefore, be excited by the fact that Dr. Littlejohn has recently addressed to the *Glasgow Herald* a letter in which he attacks the medical profession generally, and especially those members of it in Liverpool and Dublin who have actively opposed compulsory notification by the physician. He accuses his brethren of being moved by fear of losing their fees "when any of their patients, however badly housed, are removed to hospital." This statement has elicited from both Liverpool and Dublin a vigorous disclaimer. The Liverpool correspondence is so long that we are unable to publish it. In the first letter Dr. Davidson, Hon. Sec. of the Lancashire and Cheshire Branch of the British Medical Association, reminds Dr. Littlejohn that the Liverpool protest against notification emanated from the Medical Society, and was supported not only by those who were engaged in family practice, but by nearly every hospital physician and surgeon. He expresses the hope that Dr. Littlejohn will at once withdraw the accusation and express regret at having been betrayed into such an unfair representation of the action of his professional brethren in Liverpool. Dr. Littlejohn's reply to this is that he "was not aware of any formal protest of the medical profession against the notification of infectious diseases, and therefore his remarks could have no reference to such action of the profession in Liverpool."

This excuse sounds rather strange in presence of the fact that Dr. Littlejohn, at the Nottingham meeting of the Social Science Congress, defended his policy against this very protest, and against the physicians who came from Liverpool to speak the views of the profession. Dr. Davidson, in reply to this statement by Dr. Littlejohn, says:—"We in Liverpool are naturally annoyed that such a misrepresentation should be made as is contained in your letter, and especially seeing it is made by one holding the professional and public position which you hold, and which add weight and authority to the statement. I have written to you with the approval of the leading members of the profession here; I ask you to withdraw your statement, and to make such apology as I can hardly doubt you must feel is due to your professional brethren here whom you have misrepresented."

To this simple request the Medical Officer of Health for Edinburgh responds by a fresh charge, that "both at Worcester and Nottingham gentlemen who spoke of the profession in Liverpool as if they represented it used the argument that notification necessarily implied removal to a hospital, and they asked the question, what is to become of those medical men whose practice lies among the poorer classes if their patients are compulsorily removed by sanitary officials?"

Dr. Davidson has a brief and conclusive reply to this,

the second mis-statement made by Dr. Littlejohn. He says:—"This assertion has no foundation in fact. I was myself present at the Worcester meeting, and I heard no such statement made by any Liverpool medical men. I have asked several who were present at the meetings, and all are positive that nothing of the kind was said. It is an utter misrepresentation. As to Nottingham, the only Liverpool medical man who was present informs me that neither he nor anyone else from Liverpool made any such statement." [We can state of our own knowledge that no such statement was made at Nottingham by any one except Dr. Littlejohn himself.] Dr. Davidson continues:—"When I first wrote to you I fully expected to receive an immediate and frank withdrawal of this unfounded charge. You have not withdrawn it. I shall not trouble you with any further request to that effect."

The correspondence winds up with the following resolutions passed at the last meeting of the Medical Institution of Liverpool:—

"That this meeting condemns in the strongest possible manner the action of Dr. Littlejohn, of Edinburgh, in that he, while confessedly ignorant of the grounds of opposition to compulsory notification of infectious diseases by the medical men of Liverpool, should nevertheless publish the following statement—viz., 'That to-day we have the medical profession there protesting against loss of fees, were any of their patients, however badly housed, removed to hospital so as no longer to be a source of danger to the community,' and this meeting declares that such statement is absolutely void of foundation. It further desires to express its surprise and regret that Dr. Littlejohn, when challenged either to justify or withdraw his charge, should be unwilling to withdraw while unable to justify it."

Dr. Littlejohn, it will be observed, had bracketed Dublin with Liverpool in his insulting and disingenuous statement, and his having done so evoked the following correspondence, which we print in full, as it has not appeared elsewhere:—

No. I.

DEAR SIR,—My attention has been called to a letter addressed to the *Glasgow Herald*, in which a passage occurs to the effect that "Dublin follows suit" in "protesting against a loss of fees when any of their patients, however badly housed, are removed to hospital."

This phrase clearly implies that the opposition of medical men in Dublin to compulsory notification is animated by sordid personal motives.

As I have taken a leading part in that opposition both in Dublin and elsewhere, I feel myself justified in asking you to state by what authority you make such a statement, and to give reasons for supposing the medical profession in Dublin to be guilty of the motives you attribute to them. Should you not do this, I certainly think that an apology is due for the public insult you have offered the members of your own profession.

Yours faithfully,
ARCHIBALD HAMILTON JACOB.
M.D., F.R.C.S.I.

No. II.

DEAR SIR,—I must decline entering on a correspondence with you on a subject regarding which I fail to recognise your right to interrogate me.

Yours faithfully,
HENRY D. LITTLEJOHN, M.D.

No. III.

DEAR SIR,—You decline to explain or apologise for the slanderous statements which you have publicly made in reference to these physicians in Dublin who oppose the extension of the

compulsory notification system, because you do not recognise my right to interrogate you on the subject. I consider that any physician whom you have so vilified, has a right to demand that you shall substantiate or apologise for your accusations; I feel that I have a special claim to that *amende*, being, as I believe you know, the editor of the only medical journal in Ireland, the Secretary for Ireland of the Association for opposing the proposed law, and also one of the Executive of the Irish Medical Association, which organisation has actively opposed the extension of the system to Ireland.

Occupying this special relation to the controversy, I feel that I have a right to reiterate the demand contained in my last letter, and to say that, if you refuse that demand, you will, in my opinion, have descended from the position which a gentleman and an honorable physician should occupy, and taken up the same ground as that assumed by the Anti-Vivisectionists and Anti-Vaccination agitators, who pursue their purpose by means of mis-statements, and by the slanderous imputation of motives, and when called upon to prove these assertions or to apologise, always "decline entering on a correspondence."

Yours, &c.,
ARCHIBALD HAMILTON JACOB.
M.D., F.R.C.S.I.

No. IV.

DEAR SIR,—I have yours of the 10th, I regret to state that from its contents, as well as from former dealings with you, I feel re-assured in the position I took up in my last. I refer you, however, to your own words at p. 34 of this week's *Medical Press and Circular*, for a complete justification of the language of which you complain.

Yours, &c.,
HENRY D. LITTLEJOHN, M.D.

The physicians of Liverpool and Dublin can very well afford to leave Dr. Littlejohn in possession of his own peculiar ideas of good taste and of the decencies of debate. The only conclusion to be derived from the ill-temper displayed by the advocates of compulsory notification is that they must have very little argument to go upon when they are obliged to resort to abuse into which their opponents decline to follow them. We can, however, venture to assure the Medical Officer of Health for Edinburgh, that the physicians of Liverpool and Dublin are, at least, as free from corrupt motives as he is likely to be, and that they have, individually, much less personal interest to serve by opposition to notification, than he as a corporate official has in advocating it.

Notes on Current Topics.

The Dangers of Amateur Doctoring.

A PAINFUL illustration of the dangers that may be associated with amateur doctoring has recently been afforded by the death of a girl at West Malling, in Kent, through poisoning by oil of almonds, administered by the Rev. J. H. Timins, rector of the parish. The deceased, a young girl, daughter of a labourer, was a parishioner of the clergyman in question, who seems to have largely interested himself in the material as well as the spiritual ills of his flock; and in pursuance, no doubt, of very worthy desires, constituted himself their medical attendant on frequent occasions. The girl whose death he now stands charged with causing was seen by him to be in a state of bad health, and as an agreeable remedy under the circumstances he prescribed and administered to her a considerable dose of oil of bitter almonds obtained from a local chemist, by whom, however, he was duly warned as to its poisonous properties. The

defence of the reverend gentleman was based upon the fact that thirty years ago he studied medicine for a time at St. Thomas's Hospital, and that he treated the patient for apoplexy, from which he judged her to be suffering; also that oil of almonds was a harmless remedy previously used by him in the case of his own son, and so far innocuous that he had himself taken a spoonful from the same bottle out of which the dead girl had received it. It is a pitiful necessity that we are under which compels us to comment on this case at all. There can be no question that the reverend gentleman was actuated by the most benevolent intentions in the matter; there can equally be no question that the indiscriminate adoption of such principles of action by clergymen, or, indeed, by any non-professional person, is fraught with extremest danger, even to life itself. In the present instance a coroner's jury has been compelled to register a verdict of manslaughter against the Rev. Mr. Timins, who consequently stands committed for trial on that count. There is, perhaps, more of injustice than of right in a condition of things which leaves it possible for such an unpleasant complication of social relations as this to be brought into existence; and until the time arrives when it shall become a criminal matter for any unauthorised person, in the absence of dire emergency, to take upon himself the office of a medical practitioner, it can never be that human life will be safe from the pretensions of ignorant busybodies or the yet more dangerous trading of quacks. Mr. Timins is unable to urge even ordinary necessity as an excuse for his interference; medical men were resident within the immediate vicinity of the house in which the death occurred, by summoning whom it is open to us to believe the catastrophe might have been avoided.

Coming Medical Reform.

THE prospect of medical reform through the agency of an Act amending the present condition of things, to be introduced during the next Parliamentary session, would seem less distant than some persons profess to regard it. On Thursday last the Dublin branch of the British Medical Association had before it a report of the Branch Council, in which it was recommended not to accede to the request of the Medical Reform Committee of the parent Association to memorialise Government to introduce a new Bill based on the Report of the Royal Commissioners. Dr. Haughton moved the adoption of the report, to which Dr. Atthill moved an amendment to the effect that the policy of the parent Association should be supported by the Irish branch. After a lengthy discussion the debate was adjourned, on the motion of Dr. A. H. Jacob, until the 5th February. At this meeting Dr. Banks took the chair for the first time as President, and Dr. Mahomed addressed the members on "Collective Investigation." Subsequently to the meeting the annual dinner of the branch was held in the hall of the College of Physicians, Dr. Edward Hamilton in the chair.

THE outbreak of scarlatina in Belfast has lessened considerably, and last week the number in the Union Hospital was down to fifty-three, twenty-five convalescents having been discharged during that period.

False Certificates again.

AT Marlborough Street Police Court, last week, a medical practitioner named William Hindhaugh, L.R.C.P. Ed., M.R.C.S. Eng., was summoned for unlawfully and wilfully giving a false certificate of death. The case was much simplified by a formal admission of guilt on the part of Mr. Hindhaugh, who was consequently fined £5 and costs. It is instructive to note the reasons given in excuse of his conduct by the defendant surgeon, who pleaded that, though ill in bed at the time the lady referred to in the certificate died, he yet, on the urgent request of the friends of the deceased, consented to sign the necessary paper. The reports of the case are silent respecting the process of reasoning by which it can be demonstrated that a particular value attaches to any individual signature when appended to a death-certificate, provided that it be that of a registered practitioner; it is also—and this is important—silent as to the qualifications possessed by the "other gentleman" who attended Mr. Hindhaugh's patient while he himself was laid up. If this gentleman was not in a position to legally sign the certificate, it is easy to understand how besides the "urgent appeal" made by the deceased's relatives, an equally urgent necessity of the law compelled the course resorted to. If, on the other hand, the gentleman was duly qualified, then it is inexcusable folly that led to the substitution of a fraudulent signature for his.

The General Medical Council.

WE referred last week to the fact that the Executive Committee of the General Medical Council had under consideration an application by the University of Malta for recognition of its degrees within the United Kingdom, the requisition being endorsed by Earl Kimberley's expression of hope that "the law on the subject of foreign degrees may before long be altered." We echo the hope, but trust that no alteration will, as proposed, be made which will give the Medical Council authority to flood the British market with degrees of which they know nothing. They have done so in the case of preliminary education *testimonia*, and we don't imagine that there would be much difficulty in obtaining recognition for a Medical College or University anywhere if the Council had, at present, power to recognise.

The accounts of the Council for the year ending December 31 were presented. The year's expenditure was as follows:—

General Council	£3,682
English Branch	517
Scottish	„	...	271
Irish	„	...	348
Total	£4,818

Large sums were invested by the three Branch Councils during the year. The English Branch put aside £4,000, and has nearly £3,000 still banked to its credit. The Scotch Branch invested £1,200, and has a small sum in hand. The Irish Branch put by £150, and has £327 in hand. It would seem that the invested funds are as follows:—English Branch, £33,000; Scotch Branch, £3,200; Irish Branch, £2,000—total, £38,200. The visitation of examinations cost, during the past year, £467.

On a requisition from the Irish Branch Council to add the abbreviation *Hon. Caus.* after the degree held by Mr. Porter, Surgeon to the Queen in Ireland, a reply was given that the addition of the words in question is not authorised by the Medical Act. However this may be, the Branch Registrar has been in the habit of recording this addition to names in the Register, and we presume the Council will be obliged to "try back," as they did with reference to the dentists, and disrate all the honorary graduates on the list. It would be more business-like to discover these legal difficulties in the first instance. The Council, it is understood, will not meet until the usual period in the dog-days, and will not take any official notice of the medical legislation of the coming session. It is perhaps as well that this course should be adopted, considering that, on the last occasion on which a Medical Bill was before Parliament, the Council occupied many days, at a large expenditure, in arriving at no conclusion whatever.

Dublin Medical Students' Club.

THE third general meeting was held on the 16th inst. Mr. J. K. Barton, President of the Club, took the chair. Present—Surgeon Wheeler, Dr. Thornley Stoker, Dr. Cunningham, Dr. Roe, and a large number of members. Important business was transacted, the matter before the meeting being the question of limited liability. Mr. W. G. Toomey, LL.D., explained to the meeting the advantages to be gained by registering under the Limited Liability Act, and the method of doing so. The meeting ruled that the Club be "limited," and Mr. Toomey was requested to draw up Articles of Association. The proposed rules were then read to the meeting, and amended, though not finally passed, as special rules have to be framed for the registering of the Club. The committee were then authorised to take the upper part of 113 Stephen's Green West. After a vote of thanks to the committee and office-bearers for working up the Club so successfully, the meeting adjourned. Twenty-five new members will be balloted for at the next general meeting. Since writing this report, the committee have taken the premises mentioned above, and are furnishing the rooms, so that members can have the use of the reading and smoking rooms in a few days. Intending members, who must be proposed and seconded by members, will oblige by sending in their names at once to the hon. secs.

The London College of Physicians.

At the comitia meeting, January 25th, a report was submitted to the Fellows, which states that, the Council having considered the report of the visitors from the General Medical Council, does not think it necessary or desirable that any alteration should be made at present in the examinations for the licence of the College. Referring to some remarks made by the visitors on the subjects of hygiene and psychological medicine, the committee has suggested whether the College might not, with advantage to the public, institute separate and voluntary examinations on those subjects, to be followed by a special certificate or diploma. The Council, therefore, recommends the College—1. To institute a special examination on the subject of hygiene or State medicine; 2. To institute a special examination on the subject of psychological medicine; 3.

That such examinations be conducted by special examiners appointed by the College; 4. That all registered practitioners be admissible, under conditions, to either of these examinations, in order to qualify for a distinct diploma or certificate of proficiency on these subjects.

Small-pox at Nottingham.

COMPULSORY notification by the medical attendant has been in force in Nottingham for many years. Nevertheless, we are informed that, for the past twelve months, small-pox has been epidemic in the town in spite of the vigorous proceedings of the local sanitary authorities. About a fortnight ago small-pox appeared in the imbecile ward of the asylum, where a young female patient was attacked; she was at once isolated, but the disease has continued to spread, and it has been found necessary to remove at least seven cases to the garden hospital, where the small-pox patients from the town have hitherto been received. It would be interesting to know whether or not these seven cases were under the care of a qualified practitioner, or whether—with a view to concealment—the physician was excluded.

The Chemical Analysis of Drinking-Water.

A CONTEMPORARY bestows, this week, needless blame upon the United States Board of Health, which, it alleges, is unnecessarily withholding a comprehensive report prepared by Professor Mallet, on the chief processes in use in the chemical analysis of drinking-water, and made with the view of testing the absolute and relative accuracy of the results they are capable of yielding, and, as far as possible, the nature and scope of the practical conclusions that can be drawn from them for sanitary purposes. The fact is, there has been no unnecessary delay to speak of, nor a desire to withhold information. A preliminary report appeared about a month ago, and we know almost as much from this as we shall know from the fuller report, almost, if not quite, ready for publication.

It appears that nine classes of water were distributed amongst various chemists to be submitted to analysis, and without much instruction, some using the combustion process, others the albuminoid-ammonia process, and others the permanganate process. The waters consisted of several classes, as, those believed to be wholesome, those believed to have caused disease, those purposely contaminated in various ways, &c. Biological experiments were also carried out under careful supervision.

After stating the special conclusions arrived at by each chemist, the report passes on to the chemical and biological results obtained, and as contrasted with the actual and sanitary history of the waters examined. It appears that no strongly-marked generic difference is presented by the results obtained from any of the several processes for the estimation of organic matter or its elements, between the generally wholesome waters and those condemned and fairly assumed to be pernicious.

Some of the biological experiments failed to afford satisfactory results. Professor Mallet therefore concludes that it is not possible to decide as to the sanitary quality of a water by the mere use of a process for the estimation of organic matter or its constituents, and that there is no sound ground on which to establish such "standards of

purity" as have been proposed, fixing the exact amounts of organic carbon or nitrogen, albuminoid ammonia, or oxygen of permanganate consumed, that shall be permissible and satisfactory.

Compulsory Vaccination in Switzerland.

It is stated that the citizens of Basle have suppressed compulsory vaccination by a majority of 3,539 against 716 votes; also, that compulsory vaccination and re-vaccination have been abolished in the Federal army; and that the cantons of Argau, St. Gall, Lucerne, Berne, and Zurich are on the eve of following the example of Basle. It is further stated that the Prussian Government has just approved a Royal Commission to examine evidence brought against vaccination by the various delegates before the International Congresses at Paris and Cologne.

Corrosive Sublimate.

THIS well-known and powerful drug, whose virtues as an antiseptic were first made known to the world by R. Koch, is now rapidly coming into use. Tarnier employs it freely in his maternity hospital. Every attendant on entering the labour ward must wash the hands and arms in a solution of corrosive sublimate (1 in 1,000). The patient's genitals are bathed in a solution of the strength of 1 in 2,000; this is also the strength required for vaginal injections. He appears to be well pleased with the results.

Billroth has also been employing it as a surgical dressing in a case of suspected anthrax. A patient admitted into hospital had been in attendance on a sick ox, from the rectum of which he had removed masses of coagulated blood, passing the hand deeply into the cavity. Afterwards pustules made their appearance on the dorsum of the hand. It was this condition of the hand, with the attendant history, that led Billroth to a trial of corrosive sublimate, apparently of the strength of 1 in 5,000. No fever had set in after several days' employment of the antiseptic.

A Hospital Drug Bill.

A CONTEMPORARY gives in its last issue a *résumé* of the annual drug bill of one of the largest metropolitan hospitals. Taking, for example, some of the most requisite, it finds ten tons of linseed meal, at a cost of 125*l.*, required for poultices. Lint for dressing ordinary wounds cost 443*l.*; cotton-wool of all kinds, 183*l.*; carbolic acid, 223*l.*; carbolised muslin, 180*l.*; spirits of wine, 585*l.*; iodide of potassium, 80*l.*; nitrate of silver, 111*l.*; quinine, 300*l.*; cod-liver oil, 190*l.* The treatment of dyspepsia calls for an expenditure on bismuth alone of 93*l.*

THE mortality from diseases of the zymotic class continues exceptionally low throughout the kingdom. Last week the highest death-rates recorded in the large towns from these were—1·9 in Leeds and 2·4 in Hull from whooping-cough; from scarlet fever, 1·1 in Leeds and 1·8 in Sheffield; from measles, 1·1 in Liverpool and in Preston; and from "fever," 1·2 in Hull, and 1·3 in Sunderland, per 1,000 of the population. The 34 deaths from diphtheria included 13 in London, 7 in Glasgow, 5 in Edinburgh, and 3 in Liverpool. Small-pox caused 3 deaths in London, 2 in Newcastle-upon-Tyne, 1 in Nottingham, and 1 in Derby.

Proposed Cremation of Garibaldi's Body.

AN agitation has been set on foot, headed by the Senator, Professor G. Cantoni, for demanding from the Government and the family of General Garibaldi the accomplishment of his will, signified by testamentary declaration, that his remains should be incinerated at Caprera. It is the object of this movement to obtain such cremation on the occasion of the first anniversary of the death of the Great Captain.

Longevity of Medical Men.

ONE of the daily papers last week, in a review of the past year, gave some interesting statistics regarding longevity, summarising that of the medical profession, with the ages of a few of its most eminent members, thus:—John Flint South, F.R.C.S., late President of the Royal College of Surgeons of England, 85; George Samuel Jenks, M.D. Ed., F.R.C.P. Lond., 93 (he served in the Peninsula from 1812 to the end of the war in 1814, and at Waterloo); Price Blackwood Hallows, F.R.C.S., 81; Sir Robert Christison, Bart., M.D., D.C.L., LL.D., one of Her Majesty's Physicians in Ordinary, Scotland, 85; John Francis de Grave, M.R.C.P., late Master of the Society of Apothecaries, 92; John Lonsdale Minshull, F.R.C.S., 81; George Macilwain, F.R.C.S., 86; Sir James Alderson, M.D. Oxon, D.C.L., F.R.S., Physician Extraordinary to the Queen, and late President of the Royal College of Physicians, London, 87; Henry John Gore, F.R.C.S., 85; Staff Surgeon William St. George Davies, R.N., 96 (he served as Acting Surgeon in the *Norge* at the Bombardment of Copenhagen in 1807, and was, in all probability, the very last survivor of that engagement); Henry Bell, M.D., 85; George Gulliver, F.R.S., F.R.C.S., late Surgeon, Royal Horse Guards, 79; A. E. Blest, M.D. Edin., Indian Army, 85; Staff Surgeon Cotton, 87; Edward Greatrex, F.R.C.S., late Surgeon, Coldstream Guards, 83; Edward Doubleday, F.R.C.S., 84; John Haxworth, 86; Sir Thomas Watson, Bart., M.D., D.C.L., F.R.S., Physician in Ordinary to the Queen, and a former President of the Royal College of Physicians, London, 90; Inspector-General Cross, R.N., 78; James Arthur Wilson, M.D., F.R.S., 88.

THE President and Vice-Presidents of the Royal College of Surgeons have just issued invitations to the Hunterian oration on Wednesday, the 14th prox., which will be delivered by the President of the College, Mr. T. Spencer Wells, in the theatre of the institution, at three o'clock. The Hunterian Festival, to which several distinguished guests have been invited, will be given in the Library on the same evening.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 41, Bombay 25, Madras 40, Paris 26, Geneva 19, Brussels 26, Amsterdam 23, Rotterdam 30, The Hague 27, Copenhagen 23, Stockholm 27, Christiania 13, St. Petersburg 39, Berlin 23, Hamburg 24, Dresden 26, Breslau 36, Munich 27, Vienna 37, Prague 32, Buda-Pesth 28, Trieste 29, Rome 26, Turin 27, Venice 34, New York 26, Brooklyn 23, Philadelphia 22, and Baltimore 30.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

OUTBREAK OF FEVER ON BOARD THE "MARS" TRAINING SHIP, DUNDEE.—A rather alarming outbreak of scarlet fever has just occurred on board the "Mars" training ship, Dundee. The directors of the Dundee Royal Infirmary having refused to receive the patients, a temporary hospital was provided for their accommodation in the top flat of a building formerly used as granaries at Woodhaven, on the Fife shore, opposite to where the "Mars" is moored, and which is partly occupied by the officers of the vessel and their families. In all there have been about twelve cases of fever amongst the boys, but only six remain under treatment; and the flat in which they have been located has been isolated from other parts of the building.

GLASGOW DEATH-RATE.—During the week ending with Saturday, the 20th inst., the death-rate in Glasgow was 30 per 1,000 per annum, being the same as the preceding one. The rates for the corresponding periods of 1882, 1881, and 1880 were 25, 42, and 30 respectively.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 20th inst., rose from 76 to 100, and the death-rate was 22 per 1,000. Diseases of the chest accounted for 63 deaths, and zymotic causes for 11, of which 2 were due to diphtheria and 2 to scarlatina.

EDINBURGH UNIVERSITY COURT.—The Edinburgh University Court met on the 22nd inst., the Earl of Rosebery, Rector, in the chair. The following gentlemen were appointed additional Examiners in Graduation: *Medicine*—Dr. Thomas Barlow, F.R.C.P. Lond., in Practice of Physic; Dr. J. Halliday Croom, F.R.C.P. Edin. (Edinburgh), in Midwifery; Professor D. J. Cunningham, M.D. Edin. (Dublin), in Anatomy; and A. P. Aitken, D.S.C. (Edinburgh), in Chemistry. These appointments are for one year, but may be continued by annual appointment for five years. The following gentlemen were recognised as teachers of medicine whose courses of lectures should qualify for graduation in Medicine in the University in terms of Ordinances No. 8, sec. vi. (4):—Dr. Peter Young, Lecturer on Midwifery, Edinburgh; Professor George Shearer, Lecturer on Botany, Liverpool; Dr. Charles McGillivray, Lecturer on Surgery, Edinburgh; and Dr. R. Shingleton Smith, Lecturer on Physiology, Bristol.

THE TEACHING OF PATHOLOGY IN ABERDEEN UNIVERSITY.—The matter with respect to the position taken up by the students of medicine in regard to examinations in pathology was again before the Senatus Academicus of the University at a meeting held on the 20th inst. After a lengthened discussion the following resolution was adopted—viz., "That the examination for medical graduates shall be continued on the same footing as formerly, with the understanding that this shall, in the meanwhile, only apply to students now engaged in the last year of their medical curriculum; *quoad ultra* the Senatus defer the matter for future consideration."

GLASGOW.—THE SANITARY INSTITUTE OF GREAT BRITAIN.—With a view to making arrangements for the visit of the Sanitary Institute of Great Britain to Glasgow next autumn, a preliminary meeting, convened by Lord Provost Ure, was held on the 25th inst. in the Council Chamber. His Lordship presided, and the following gentlemen attended as a deputation from the Institute:—Professor de Chaumont, M.D., F.R.S., Chairman of Council; Professor W. H. Corfield, M.A., M.D.; Mr. H. H. Collins; Mr. W. Eassie, C.E.; Mr. Rogers Field, B.A., M. Inst. C.E.; Mr. E. C. Robins, F.S.A.; and Mr. E.

White Wallis, F.M.S., Secretary. The Chairman having given the deputation a hearty welcome, Professor Chaumont delivered an address on the functions and works of the Institute. The meeting, on the motion of the Lord Provost, seconded by Professor Gairdner, unanimously passed a resolution expressing gratification at the prospect of the annual Congress of the Institute being held in Glasgow, commending the Institute to the citizens as deserving of their support, and pledging itself to do everything in its power to make the Congress a success. It was also agreed that a fund be raised by public subscription to meet all the local expenses of the Congress, calculated at between £500 and £600.

ROSLIN.—OUTBREAK OF TYPHOID FEVER.—For some time past typhoid fever has been prevalent in the Roslin district, and at present over a dozen cases are under treatment. Towards the end of the year no fewer than from twenty to twenty-five cases occurred at the same time in Roslin, but these were of a mild character, and most of them are now convalescent. The Lasswade Parochial Board, as the local authority for the district, made inquiry into the matter, and had an analysis of the water made by Mr. J. Falcooner King, who reported unfavourably in regard to it. A meeting of the inhabitants was forthwith held, at which it was resolved to petition the local authority to have Roslin formed into a water and drainage district. Pending the carrying out of this arrangement, steps were taken to secure forthwith a supply of wholesome water. Applications were made to the Edinburgh and District Water Trust, and permission obtained to tap their main. With equal promptitude pipes were ordered, and the laying of these has so far progressed that it is expected the water will be at once available.

MEDICAL SPECIALISTS AS PUBLIC LECTURERS.—Dr. Barr, Aurist, Glasgow, lectured on "The Ear and Hearing" to a large audience in Brown Street Institute, Galston, on the 25th inst. We have no earthly objection to this procedure—that of public lecturing on one's medical speciality; but it were well that the profession should legislate, so to speak, on what is and what is not legitimate or professional enterprise. Could a syphilographer, for instance, with equal justice lecture on syphilis? And if not, *why* not?

AMBULANCE LECTURES.—This eccentric phase of medical enterprise still shows signs of vitality. The first of a course of five lectures on "First Aid to the Injured" was given on Friday, the 26th inst., in the School of Domestic Economy, Edinburgh, by Dr. A. G. Miller, whether in connection with a "Christian Association" does not appear. After briefly enumerating the chief bones and joints, and their peculiarities, the lecturer went on to explain the chief causes and varieties of fractures, and the signs by which fractures and dislocations might be known. He then demonstrated how first aid might be given in cases of fracture. The lecture was well attended.

NEW RULES FOR STUDENTS IN THE UNIVERSITY OF EDINBURGH.—The following form of a proposed alteration of Section IX. of Ordinance No. 5, regulating the time at which candidates for graduation in medicine may present themselves for examination on botany, natural history, and chemistry, was agreed to:—"Section IX. of Ordinance No. 5, *Edinburgh* No. 2, as altered by Order of Her Majesty in Council, of date 17th May, 1876, to be deleted, and the following to be substituted therefor:—"That students who profess themselves ready to submit to an examination on the first division of these subjects at the period of examination immediately preceding their second winter session of professional study may be admitted to examination at that time, provided always that students who commence their medical studies in the summer session shall not be admitted

to a degree in medicine, unless their course of study, subsequent to the completion of the summer session in which they commence their medical studies, shall not be less than the minimum course of four years prescribed in Section IV. hereof." It was ordered that the proposed alterations should be submitted the Chancellor of the University for his sanction; and, if his sanction should be given, that the necessary steps should be taken to submit the matter to Her Majesty in Council for her approval. The above regulation will be a great boon to students, but it leaves untouched the regulation compelling the student to wait for three winter sessions before he can present himself for his examination in anatomy. At present, the student is so hampered by lectures that he has only six or nine months to prepare for his final examination. Owing to vested interests, the old regulation has existed for over twenty years, so that we may hope that in another twenty the first and second examinations will be approximated. The present system necessitates three courses of anatomy, instead of one as required by the University. Still, the student must be thankful for small mercies; but if students were to combine for the furtherance of their own interests, such abuses as we have so frequently to expose would soon be abolished.

Literary Notes and Gossip.

It is announced by Professor Panum, President of the Organization Committee, and Herr Lange, General Secretary, that the International Medical Congress will be held at Copenhagen, from the 10th to the 16th of August, 1884.

DR. V. BOMPIANI, of Dicomano, Florence, who last year published an Italian translation of the work on "Regressive Paralysis," by Dr. W. H. Barlow, of Manchester, is, we are informed, at present engaged in translating the same author's monograph on "Pseudo-hypertrophic Paralysis."

ACCORDING to the annual report before us of the Commissioner of Education in the United States, it would appear that during the last decade the number of medical schools in the United States doubled, and the number of students trebled. It gives the list of regular schools as seventy-two; of eclectic schools, six; of homeopathic schools, twelve.

CONSIDERABLE interest was manifested in Edinburgh on Monday last in the sale of the library of the late Dr. John Brown, the well-known author of "Rab and his Friends." The library contained a curious mixture of works on medicine, poetry, theology, and art. Many of the books and prints were first copies, which had been presented to the deceased physician by distinguished English and American authors.

THE *Practitioner* commences a new volume with the January issue, and for the first time the custom of publishing the magazine with cut edges has been introduced, whereby its appearance is improved, and the comfort of those who read it much augmented. This particular innovation of cut edges, first adopted by ourselves many years ago, is now very generally recognised as adding to the usefulness of periodical publications.

THE past half-year was not a prolific period for new books in medical and surgical literature, if we may take Messrs. Churchill's recently published list as an index. Fifteen new books, some of which might not inaptly be classed as pamphlets, seven new editions, five museum catalogues and hospital reports, one translation from the French, and seven pamphlets, are the sole products of "work between covers" of about 20,000 medical men, as represented by the leading house during six months. Truly a poor display.

MR. E. CRESSWELL BABER, of Brighton, has issued a pamphlet in which the attention of the profession is drawn to the importance of the recognition and early treatment of adenoid vegetations of the naso-pharynx. The author gives a

well-drawn outline of the subject, insisting especially on the effects produced by this affection on the organ of hearing. The subject is one well worthy of attention. We have had frequent experience of symptoms connected with naso-pharyngeal trouble closely simulating those of grave pulmonary disease.

WE have to deplore the loss of an author of considerable repute, not only in his own country, but throughout Europe, in the person of Dr. Forsyth Meigs, whose death from pneumonia, at the age of sixty-four, is announced in the Philadelphia medical journals. Dr. Meigs' domain in practice and in literature lay in the treatment of diseases of women and children, on which subjects he wrote two trustworthy and original guides. His text-book on children's diseases has run through several editions, and was certainly one of the most scholarly productions emanating from the profession on the other side of the Atlantic.

THE unprecedented success of Dr. Quain's "Dictionary of Medicine" is one of the most striking phenomena in modern literature; it is, moreover, a satisfactory indication of the reading spirit prevalent among practitioners, who have shown, by so rapidly obtaining copies of this representative work, that they are diligently alive to the necessity of constantly increasing their own stores of information by utilising the matured experience of admitted authorities in medicine. A second edition of the Dictionary is almost ready, and we learn that our suggestion to divide it into two volumes will be followed, so that one feature urged against the work, its unwieldy size, will no longer detract from its usefulness.

THE literature of Temperance furnishes some interesting statistics. We have a batch of leaflets and popular tracts for the people before us, by Dr. Norman Kerr, Dr. Richardson, and other well-known and zealous leaders of the work which give an insight into the causes that have led to so serious a falling off in the revenue from intoxicating drinks. Thus, we find that in Newcastle alone 40,000 have put on the Blue Ribbon; in Leeds, 25,000; in Leicester, 23,000; Swansea, 11,040; Bristol, 20,000; Stockport, 20,000; Brighton, 20,000; Birmingham, 67,000; London Tabernacle, 12,000; Nottingham, 20,000. Since October, 1880, one million people have donned the Blue Ribbon, and 554,000 people have signed the pledge, in England and Wales.

TO the younger members of the profession to whom emigration is a favourite idea, and who see a brighter future in store for enterprise in our Indian and Colonial dependencies than in our over-stocked towns at home, *Street's Indian and Colonial Directory for 1883* (just to hand) will have particular attractions. In it will be found the population of all the great centres, the names and addresses of the principal business firms, banks, medical men, lawyers, chemists, &c., the official residences of Government officials, consuls, &c., the latitude and longitude of the towns, the lines of steamers out and home, and every information which a person on the eve of starting finds not only useful, but in many cases absolutely necessary. What more useful item to a young medical aspirant than that which enables him first to get at the population of various towns and compute the number of practitioners already resident before he determines in which to settle.

STATISTICIANS have at various times endeavoured to gauge the extent of medical practice in civilized countries, but we believe the most reliable estimate places the number of qualified practitioners of medicine on the globe at about 180,000. Of this number there are about 11,000 authors or contributors to medical journals. The latter may be thus divided—United States, 2,600; France, 2,400; Germany, 2,200; England and Colonies, 2,800; Italy, 600; Spain, 300; other States, about 1,000. In 1880 the number of medical books and pamphlets published, exclusive of journals, was computed at 1,643—viz., France, 541; Germany, 364; United States, 310; Great Britain, 182; other countries, 246. The last statistics regarding medical journals were also made up to the end of that year, giving an aggregate of 655 journals—viz., in the United States, 156; Germany, 129; France, 122; Italy, 65; Great Britain and Colonies, 54; Spain, 24.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list,

December 20th :—"Anatomy, Descriptive and Surgical," by Henry Gray, F.R.S., Tenth Edition, by T. Pickering Pick, F.R.C.S. "The Systematic Treatment of Nerve Prostration," by W. S. Playfair, M.D. "Notes from Sick Rooms," by Mrs. Leslie Stephens. "A Pharmacopoeia of Selected Remedies," by E. A. Kirby, M.D. "On Duty under a Tropical Sun," by Major Leigh Hunt and Dr. A. S. Kenny. "Transactions of the Pathological Society of London for 1882." "Braithwaite's Retrospect," July to December, 1882. "A Manual of Nursing," by C. J. Cullingworth, M.D. "Army Medical Organisation," by Surgeon-Major G. J. Ewart, M.D. "Diseases of the Prostate," by Sir Henry Thompson, F.R.C.S. (Fifth Edition). "Epitome of Skin Diseases," by Drs. Tilbury and Colcott Fox (Third Edition). "The Causation of Sleep," by James Capple, M.D. "On Some Rare and New Diseases," by Sir James Paget, F.R.S. "Text-Book of Pathological Anatomy and Pathogenesis," by Ernest Ziegler; translated by Donald Macalister, M.A., M.B.

Correspondence.

"TRANSFUSION SOLUTION."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In an interesting article on Transfusion, by Dr. Jennings, in your valuable journal of Jan. 3rd, he gives as his formula for a saline powder to be dissolved in a pint of water at 100 F. with alcohol for intravenous injections as a substitute for human blood—

- Chloride of sodium, 50 grs.
- Chloride of potassium, 3 grs.
- Sulphate of soda, 2.5 grs.
- Carbonate of soda, 2.5 grs.
- Phosphate of soda (Na₂PO₄) 2 grs.

I want to have his powders made up, but became confused on reading a passage in Braithwaite's 69th volume, in which Dr. Volkmann recommends most of the same chemicals, but in larger doses, for similar purposes. Dr. Volkmann uses *nc* sulphate of soda, and instead of chloride of potassium uses chloride of potash, a well-known oxidiser of the blood, and Dr. Jennings' phosphate of soda (Na₂PO₄) is not that of the Pharmacopoeia, which contains 2NO, HO, PO₅, with 24HO water of crystallisation. The printer has placed some of the units on decimal points, and *vice versa*, and, like many of the chemists, may call bicarbonate of soda carbonate, as they do here. All this may appear hypercritical, but it is not so intended. "I really want to know, you know," as Dickens puts it, because I have been at great trouble to make for myself a transfusion apparatus on Rousell's principle, minus the stabbing lancet, which has to be used, before applying the cupping glass, as an ordinary lancet, and I am anxious to have my box supplied with the correct powders Dr. Jennings has used so successfully without having to send to London for them.

I am, yours, &c.,
TRANSFUSION.

Taunton, January 25.

[The proportions recommended by Mr. Jennings are those which it would be advisable to follow, inasmuch as they are based on the proportions in which the salts exist in the blood.—Ed.]

PASS LISTS.

Royal College of Physicians of London.—The following candidates having passed the required examinations were admitted Members of this College on January 25th :—

Ashby, Henry, M.D. Lond., Manchester; Beckett, John, M.D. Glasg., Widdemere; Carpenter, Alfred, M.D. Lond., Croydon; Haig, Alex., M.B. Oxon., 23 Chesham Villas, W.; King, David Alexander, M.B. Lond., 51 Pembroke Villas, W.; McConnell, James Frederick Parry, M.D. Aberd., Calcutta; Phillips, Sydney Philip, M.D. Lond., 18 Knorr Place, W.; Richardson, Adolphus Joseph, London Hospital, E.; White, William Hale, M.D. Lond., 4 St. Thomas Street, S.E.

The following candidates having passed the required examinations were admitted Licentiates on January 25th :—

Allen, Frank J., Shepton Mallet; Bateman Hinton E., St. Bartholomew's Hospital; Boxall, Robert, Cranleigh, Guildford; Browne, Ralph H., Guy's Hospital; Buol, Florian, Davos Platz, Switzerland; Calger,

Frederick F., St. Thomas' Hospital; Chadwick, Charles M., London Hospital; Cockburn, Lestock W., St. Bartholomew's Hospital; Oodd, Arthur F. G., 72 Clarendon Road, W.; Coward, Richard C., 41 Penywern Road, S.W.; Dimsey, Edgar R., Middlesex Hospital; Etches, William B., Guy's Hospital; Graham, Samuel, Carnaughill, Lironiel, Belfast; Grant, James Alexander, M.D. McGill, 103 Guildford Street, W.C.; Griffith, Walter S. A., St. Bartholomew's Hospital; Guillim, Richard D. H., Marlborough; Hebbert, Charles A., 7 Sanctuary, S.W.; Jones, Owen Clayton, City of London Hospital; Jones William H. F., 28 Duke Street, W.; Kilham, Charles S., West Pelton, Chester-le-Street; Orford, John, 27 Villa Road, S.W.; Paget, Charles E., 21a Princes Street, W.; Palmer, Frederick S., M.D. Brussels, East Sheen, S.W.; Power, Charles J., 3 De Laune Street, S.E.; Prangley, Henry J., West Cowes; Rygate, David J., 128 Cannon Street Road, E.; Salmon, Arthur Guy, 87 Granville Square, W.C.; Sheppard, William J., Rotherwood, Putney, S.W.; Shore, Thomas W., 43 Beaumont Street, W.; Spitzly, John H., 9 Grange Road, N.; Sonderland, Septimus, Montague Road, Edgbaston, Birmingham; Turing, Edward T., University College Hospital; Travers, Geoffrey F., 18 Nevron Road, S.W.; Tressidder, Edward S., Guy's Hospital; Wakley, Thomas, 86 Redcliffe Gardens, S.W.; Waring, John Arkie, 39 Princes Gardens, S.W.; Winder, William H., Cheetham, Manchester; Wynter, Walter E., St. Margaret's, Twickenham.

Boys College of Surgeons of England.—The following candidates, having passed the required examination for the diploma, were admitted Members of the College on Monday, January 22nd :—

Armstrong, A. J. Mackenzie, L.R.C.P.Ed., Chippenham Road; Atkinson, William, M.D. Q.U.L., Camden Town, Black, William Jones, L.S.A., Manchester; Burman, F. James, Wath, near Rotherham; Chadwick, John, L.S.A., Rochdale; Davies, John Thomas, L.R.C.P.Ed., Rhyll; Fink, George Herbert, L.S.A., Regent's Park College; Fletcher, John, L.S.A., Manchester; House, F. W. M'Dowall, L.S.A., London, F.; Hudson, O. Henderson, Sheffield; Jackson, John Wm., L.R.C.P.Ed., York; Jones, Arthur, Ormskirk; Keess, Arthur, L.R.C.P.Ed., London, W.C.; Liptrot, Alfred Bailey, Wigan; Logan, Robert, M.D., M'Gill Coll., Michigan; Mead, Rivas, M.B. Ed., Whitby; Owen, J. F. Holland, Rainhill, Liverpool; Rowell, Robert Henry, L.S.A., Houghton-le-Spring; Young, John More, M.B. Glasg., Rothwell, Northampton.

The following were admitted Members on January 23rd :—

Arthy, G. F. Seaman, Manchester; Buck, Lewis Archer, Newmans Row; Gresswell, Albert, Louth, Lincolnshire; Holt, Henry Lyttleton, L.R.C.P.Ed., London, W.; Holton, Richard, L.S.A., Lincoln; Hunt, Edwin Guy, Halesowen; Lane, Benjamin Hugh, L.R.C.P.E., London, S.W.; Marsden, James Aspinall, Camberwell; Rand, St. John Outlaw, Northampton; Salter, Stephen Thomas, London, W.C.; Ward, Anthony Arthur, New Cross; Williamson, H. H. Oldrick, Mildmay Park; Wilson, Alexander, Manchester; Uait, James Arthur, L.R.C.P.Ed., Walsall.

The following were admitted Members on January 24th :—

Albert, Henry Louis, Sloane Street; Bernays, Adolphus Vaughan, M.B. Cantab., Birmingham; Brodie, Charles Gordon, Isle of Wight; Davidson, Hugh Horgan, L.R.C.P.Ed., Aldeburgh; Davy, Thomas George, Exeter; Dowson, Walter, London, E.; Dyer, Sidney Reginald, Harlesdon; Frampton, Fredk. Thom., L.R.C.P.Ed., London, W.; Harrison, Charles, L.S.A., Braintree; Keatinge, Henry Bottinger, London, S.E.; Muirhead, M. Alexander, Jamaica, West Indies; Orford, John, L.R.C.P.Lond., Ipswich; Owen, Herbert, Coventry; Payne, I. Rowland, L.R.C.P.Ed., Coleford; Pearse, Frederick Edward, Frome, Somerset; Power, Charles John, L.R.C.P.Lond., Tokyo; Roughton, E. Wilkinson, Brook Green; Saneyoshi, Yasuzumi, Tokio, Japan; Sparke, Claude Stephen, L.S.A., Guildford; Taggart, James Henry, Idminton, Wilts; Tuozeimann, E. Waldemar von, Wimbledon; Williams, Arthur John, London, E.C.

The following were admitted Members on January 25th :—

Bluett, James D., Montague Street, W.C.; Browne, Ralph H., L.R.C.P.Lond., Southend, Essex; Bruce, Robert M., L.S.A., Lordship Lane, Dulwich; Buksh Raheem, Calcutta; Coward, R. Courtenay, L.R.C.P.Lond., Penywern Road, S.W.; Dent, H. L. E., L.S.A., Woolwich; Gaudin, George C., L.R.C.P.Ed., Jersey; Goddard, Charles E., Cambridge Gardens; Huntington, William, Liverpool; Long, John W. F., London, S.E.; Paley, Frederick J., Bournemouth; Pipeon, Henry W., Clifton, Bristol; Preaderville, Arthur de Cornwall, Rd.W.; Shore, Thomas W., L.R.C.P.Lond., Southampton; Spitzly, John H., L.R.C.P.Lond., Canonbury; Tatham, Charles J. W., Dallington, Sussex; Wallis, Frederick C., Southampton.

The following were admitted Members on January 26th :—

Bewes, E. Antis, L.R.C.P.Ed., Ladbroke Grove; Champ, J. Howard, L.S.A., Chelmsford; Downes, Howard, Canonbury; Dunsey, E. Ralph, L.R.C.P.Lond., Highgate; Harding, C. O'Brien, Hornsey; Levers, A. H. N., L.S.A., Gower Street, W.C.; Norry, W. Augustus, L.S.A., Wokingham; Partridge, W. Thomas, Luton; Stewart, E. Charles, Clifton Gardens; Wynter, W. Essex, L.R.C.P.Lond., St. Margaret's, Grün, E. Ferdinand, Putney.

The following were admitted Members on January 29th :—

Cave, E. John, Melbury Osmond; Dalton, A. John, South Norwood; Fairles, A. William, London, W.; Griffin, A. Watson, Peterborough; Harlock, Harry, Ely; Longman, Arthur Andover; Meller, C. Booth, Newport, Isle of Wight; Montgomery, W. A. D., Toronto; Pflimmer, H. G., Waldegrave Road, S.E.; Roberts, Henry, Shaftesbury; Scanlan, A. de Courcy, Fastbourne.

Notices to Correspondents.

Correspondents requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and

avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

EXAMINATION QUESTIONS.

THE following were the questions set at the last examinations at the Royal College of Surgeons of England for the diploma of Member.

Examinations on Surgical Anatomy and the Principles and Practice of Surgery.

1. The femur being fractured in its upper third, just below the trochanter minor, enumerate all the muscles which might displace the upper fragment, grouping them according to their actions. Give their origins and insertions.

2. Mention, in the order in which they occur, beginning at the external surface, the parts divided in the operation of opening the colon in the left loin. Name the structures which serve you as guides, and those to be avoided.

3. What are the causes and signs of suppuration within the antrum? Give the appropriate treatment.

4. Give the usual symptoms of intra-cranial suppuration following an injury to the head. After what class of injuries are such symptoms most common? In what situations may the pus be found? What are the indications for surgical treatment?

5. Give the symptoms, course, and treatment of purulent ophthalmia of infants.

6. What untoward events might occur during the employment of the taxis? How are they to be recognised and met?

Candidates must answer at least four (including one of the first two) of the above six questions.

Examination on the Principles and Practice of Medicine.

1. What are the symptoms of tubercular meningitis, the conditions under which it occurs, and the means of distinguishing it from the diseases which it most resembles?

2. Describe the symptoms, physical signs, and treatment of aneurism of the arch of the aorta.

3. What are the causes and symptoms of jaundice?

4. Enumerate the official preparations which contain mercury: give the dose of each, and briefly state their chief uses.

Candidates must answer three of the four questions, including question No. 4.

Examination on Midwifery and the Diseases of Women.

1. Under what conditions does rupture of the uterus take place? What symptoms and signs indicate its occurrence?

2. State the conditions under which forceps-delivery is called for.

3. You are called to a patient three weeks after delivery, who has a painful fixed swelling occupying the left iliac fossa, with febrile symptoms. What is such a case likely to be? What course is it likely to run? How would you treat it?

4. What are the causes of hæmorrhage from the unimpregnated uterus?

Candidates must answer three of the four questions.

DR. ALEXANDER WEISS (Arad, Hungary) will please accept our best thanks.

DR. WILTSHIRE.—Early space will be given to your paper "On Abdominal Pulsation."

MR. W. H. W. (London).—Thanks for the information, which you will find has been utilised in another column.

MR. GARSIDE.—1. There is every reason for supposing that Gross's Surgery maintains the high excellence it originally possessed under its present form. The new edition is announced by Messrs. Smith, Elder, and Co. We cannot answer your query on the subject of the arrangement pursued in the work. 2. If you will communicate with our publishers they will forward the copies you require.

LUPUS.—Dr. Bulkeley's work on "Eczema" will afford you the information you are seeking.

MR. SHANN (York).—Report arrived too late for insertion in present number. Proof shall be sent you before our next.

DR. F.—Sentiment is at all times a powerful opponent to progress; but in many instances the objections raised on sentimental grounds deserve to be considerably regarded, and we do not think any good can ever arise from deliberate outrage inflicted on the feelings of those who dissent from the conclusions of scientific thinkers. Your plan is too crude to meet with the success you appear to anticipate for it.

MEDICO-CHIR.—The discussions which take place on papers read before the Medico-Chirurgical Society are now reported under the authority of the Society, and will appear with the cases in the annual volume of Transactions.

MEETINGS OF THE SOCIETIES.

EDINBURGH OBSTETRICAL SOCIETY.—This (Wednesday) evening, at 8 p.m.—1. Dr. R. Milne Murray, Note of a Case of Inversion of the Uterus occurring immediately Post-partum, and resulting in Spontaneous Amputation.—2. Dr. David Lindsay (communicated by Prof. Simpson), Case of Twins with Exomphalos and other Deformities.—3. Dr. E. Bruce, A Third Case of Resuscitation of the New-born Infant.—4. Dr. P. Young, Hæmorrhage during Labour.

ROYAL INSTITUTION.—Thursday, Feb. 1st, at 3 p.m., Professor Dewar, "On the Spectroscope and its Applications."

HARVEIAN SOCIETY OF LONDON.—Thursday, Feb. 1st, at 8.30 p.m., Mr. W. H. Lamb, "On a Case of Pleuro-pneumonia."—Mr. H. C. Stewart, "On Fevers and Exanthems treated by Antiseptics."

ACADEMY OF MEDICINE IN IRELAND.—Thursday, Feb. 1st, at 8 p.m.—Specimens exhibited by card: Dr. D. J. Cunningham, Specimens of Frozen Sections of the Human Body.—Mr. P. S. Abraham: 1. Specimen illustrative of the occurrence of Two Superior Vena Cava in a Human Subject; 2. Sections of certain Tissues in Lower Animals.—Mr. J. F. Knott: 1. Sections of Human Hair-follicle, demonstrating the connection of Henle's and Huxley's Sheaths; 2. Frog's Nerve, showing Lantermann's notches; 3. Termination of Nerve in Frog's Muscle, showing Bremer's "End doide."—Business: Address by the Chairman,

Alexander Macalister, Esq., F.R.S. "History of Anatomy in Dublin."—Papers: Dr. J. M. Purser, "On the Refractory Period of the Auricle of the Heart."—Mr. P. S. Abraham: 1. "Notes in Comparative Histology." 2. "Note on the Musculus Sternalis in a Human Fetus."—Dr. C. Cameron and Mr. P. S. Abraham, "Notes on Preliminary Experiments on the Physiological Action of Fluoride of Sodium."—Mr. J. F. Knott, "The Accessory Nerve of Willis."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Friday, Feb. 2nd, at 4 p.m., Professor Parker, "On the Metamorphosis of Suctorial Fishes and Batrachia."

ROYAL INSTITUTION.—Saturday, Feb. 3rd, at 8 p.m., Mr. E. Bosworth Smith, On Sir John Lawrence and the Mutiny, 1857.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Monday, Feb. 5th, at 4 p.m., Professor Parker, "On the Metamorphosis of Suctorial Fishes and Batrachia."

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—Monday, Feb. 5th, at 8 p.m., Inaugural Address by the President.—Casual Communications: Mr. Sewill will open a discussion on the Proofs of the Present Theories of Caries in the Teeth.—Mr. Stevenson will explain his Electric Lamp.

Vacancies.

Cashel Union, Cashel Dispensary.—Medical Officer. Salary, £120, and £20 as Medical Officer of Health. Election, Feb. 14th.

Clinical Hospital and Dispensary for Children, Manchester.—Honorary Surgeon. Applications to be forwarded to the Secretary not later than Feb. 6th.

Loughborough Dispensary and Infirmary.—Resident House Surgeon. Salary, £100, with furnished apartments, &c. Applications to be sent to the Secretary not later than Feb. 2nd.

Middlesex Hospital.—Dental Surgeon. Applications to be sent to the Secretary-Superintendent on or before Feb. 2nd.

New Ross Union, Fethard Dispensary.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election, Feb. 8th.

Royal Surrey County Hospital.—House Surgeon. Salary, £75, with board, &c. Applications to be sent to the Assistant Secretary on or before Feb. 6th.

Appointments.

BARRS, A. G., M.D. Ed., M.R.C.S., Honorary Physician to the Leeds Public Dispensary and to the Leeds Fever Hospital.

COLGAN, F. P., L.R.C.S.I., L. & L.M.K.Q.C.P.I., Physician to Bagnalstown Fever Hospital.

GAYTON F. C., M.B., C.M. Aber., M.R.C.S., Senior Assistant Physician to the Surrey County Asylum.

LOWE, G., M.B. St. And., L.R.C.P. Ed., Medical Officer for the Third District of the Henstead Union.

MAKINS, G. H., F.R.C.S., Resident Assistant Surgeon to St. Thomas's Hospital, London.

PERKINS, G. C. S., M.B., C.M. Ed., M.R.C.S., Medical Officer for the Exmouth District of the St. Thomas's Union.

PHILLIPS, S. P., M.D. Lond., M.R.C.S., Physician for Out-patients to St. Mary's Hospital.

SMYLY, W. J., M.D.T.C.D., L.K.Q.C.P.I., Obstetric Surgeon to the City of Dublin Hospital.

STUDDERT, R. C., M.D., B.Ch. Dub., Medical Officer of Health for the Erith Urban Sanitary District.

Births.

BRUCE.—Jan. 25th, at 70 Harley Street, London, the wife of J. M. Bruce, M.D., F.R.C.P. Lond., of a son.

DICKENSON.—Jan. 23rd, at 11 Upper Merrion Street, Dublin, the wife of Dr. Newton Dickenson, of a daughter.

NEARY.—Jan. 18th, at 11 Holles Street, Dublin, the wife of Dr. E. J. Neary, 1 Victoria Terrace, Howth, of a son.

SMYTH.—Jan. 25th, at Felham House, Poole, Dorset, the wife of Hatton Smyth, M.D., of a son.

Marriages.

HOYLAND-HARDY.—Jan. 25th, at Hatfield Parish Church, Yorks. S. S. Hoyland, M.R.C.S., to Mary, daughter of G. Hardy, L.L.D.

LEIGH-JONES.—Jan. 24th, at St. John's Church, Cefn Coed, Breconshire, William Watkin Leigh M.R.C.S. Eng., L.R.C.P., of Llanfalon, Glamorganshire, to Jessie Louisa, youngest daughter of William Jones, Esq., of Glanvrafol, Cefn Coed, Breconshire.

Deaths.

BLACKMORE.—Jan. 20th, at Byrom House, Quay Street, Manchester, Edward Blackmore, F.R.C.S., aged 76.

DICKINSON.—Jan. 13th, at Ealing Dean, W., Deputy Surgeon-General J. E. Dickinson, of the Madras Army, aged 57.

DUKE.—Jan. 18th, at Meerut, from an accident, Surgeon-Major W. A. Duke.

JOHNSTON.—Jan. 3rd, Dr. R. G. Johnston, Woodhouse Eaves, Leicestershire.

MASON.—Jan. 18th, at Sunnyside, Ayr, James Lindsay Mason, M.D., of Brailford, Derby.

PARSONS.—Jan. 22nd, at Ivanhoe House, Newhaven, Sussex, Elizabeth Annie Broadbent (Lillie), the wife of Charles Parsons, L.R.C.S.I. & L.K.Q.C.P.I., L.M., aged 81.

PAULL.—Jan. 18th, at Leman Street, Truro, Alexander Paull, Surgeon, aged 69.

O'BRIEN.—Jan. 21st, at Johnstown Bridge, Dr. O'Brien, aged 87.

ON

THE TREATMENT OF SOME OF THE FORMS OF VALVULAR DISEASE OF THE HEART. (a)

By A. ERNEST SANSOM, M.D., F.R.C.P. Lond., Physician to the London Hospital; Senior Physician to the North-Eastern Hospital for Children, &c.

(Continued from page 93.)

LECTURE II.—MITRAL REGURGITATION—(Continued).

Morbid Anatomy—Mitral Regurgitation in Anæmia, in Neuroses of the Sympathetic, in Acute Fevers, in Rheumatism, and in Conditions of High Arterial Tension—Treatment to Restore Compensation—Digitalis—Belladonna—Cassa—Caffeine—Convallaria Maialis—Morphia—Alkalies—Iodides, &c.

Let us now suppose that, owing to rheumatic endocarditis, the mitral valve has been rendered incompetent. It is well known that such may be the case, and yet the subject of such incompetence present no sign nor symptom of deviation from health. We are familiar with cases manifesting the murmur of mitral regurgitation in childhood, who pass through the period of adult-life without suffering from the distresses of cardiac disease, and who, perhaps, ultimately succumb to an affection the course of which the valvular imperfection has in no wise sensibly modified. In such cases, the valvular imperfection has become compensated. Supposing a regurgitation just instituted, the first effect is upon the left auricle, which is now made to contain a quantity of blood greater than normal by so much as gushes into the auricular cavity at each systole. The effect is to distend and to dilate the auricle. The left ventricle, too, is filled more rapidly than under normal conditions, because the blood from the auricle enters it under pressure the moment that diastolic relaxation permits. Such entrance of blood is more free than the normal. Hence, dilatation or hypertrophy of the left ventricle, or a

tendency thereto. The most important of the induced conditions is, however, that of the pulmonic circulation. The reflux current overfills not only the auricle but the pulmonary veins and the pulmonic capillaries. Against such resistance comes the force of the right ventricle in systole, which in opposing resistance becomes hypertrophied. The hypertrophy of the right ventricle is essentially conservative, and the increased tension in the pulmonic circulation is an essential condition of compensation. The sign of such heightened tension and therefore of compensation is, as long ago pointed out by Skoda, accentuation of the pulmonic second sound in the second left interspace.

Observation of the degree of pronunciation of the pulmonary second sound is of the highest importance as regards the treatment of mitral regurgitation. It is in a considerable degree, a measure of the amount of such regurgitation. If the aperture caused by incomplete mitral closure in systole be small, the pulmonic tension is only slightly increased, and the pulmonic second sound may not be perceptibly intensified; but, if the gap be wide, the tension, supposing the two ventricles to be in an efficient condition of compensatory hypertrophy, is great in the pulmonic circuit, and the second sound in the pulmonic area is very loud. If afterwards the loudness of such second sound is found to diminish, such sign is of very high importance. It suggests that the compensatory hypertrophy of the right ventricle is beginning to fail, that dilatation is in excess, and that the tension in the pulmonary artery is reduced by so much as regurgitates through the tricuspid orifice. Of course, the other signs of tricuspid regurgitation should be taken in conjunction with this; but I know of no sign which is so valuable a guide for treatment.

As the left auricle is over-filled in proportion to the amount of blood regurgitating, so is the aorta, and from it the systemic arteries, ill-supplied. A diminution occurs in the normal quantity of blood propelled to the tissues; in the veins circulation is retarded, and the normal content augmented. There are arterial anæmia and venous plethora. The institution, however, of compensatory hypertrophy of the right ventricle rectifies the ill-supply to the aorta. The increased pressure in the pulmonic circuit at the time of systole opposes the reflux into the auricle, and the current

(a) Delivered before the Medical Society of London.

thus opposed is urged in normal amount into the aorta. So, even supposing that the force of the left ventricle be not augmented, increased force of the right may restore the equilibrium by inducing a pressure in the auricle equivalent to that afforded by a competent valve.

As regards the mode of production of compensatory hypertrophy, I would draw attention to an excellent chapter in Dr. Milner Fothergill's work. (a) The practical question when a patient comes before us who presents signs of mitral regurgitation, the legacy of rheumatic endocarditis, is this: Is the valvular imperfection duly compensated or not? Subjective symptoms may tell us of such want of compensation, but they are often deceptive. In addition to the auscultatory sign I have mentioned, we may get valuable evidence from the use of the sphygmograph and cardiograph. The former may tell us of a fairly normal tension in the systemic arteries, or otherwise; the latter, by recording the duration of systole and diastole, may tell us how far the normal rapidity of filling of the ventricle is exceeded, and this may give evidence of the amount of regurgitation.

Supposing that we are satisfied that there is due compensation, medicinal treatment may be entirely unnecessary. I have no doubt that a vast amount of injury has been done to patients by a shaking of the head of the auscultator over the subject of a mitral murmur, who, perhaps, was no worse at the time of examination than he was ten, twenty, or thirty years before, and who might continue uninfluenced for harm by the cardiac complication all his days. He should be cautioned against strain, against exposure, and against irregularities. He may be better occasionally for treatment by iron-tonics, cod-liver oil, or strychnine; but any special cardiac treatment is out of place.

Not so, however, if there is evidence that compensation is beginning to fail. I will pass in brief review the chief agents which are of service in such case:—

1. Digitalis is *facile princeps* of drugs in the treatment of imperfect compensation. The researches of modern observers—Fuller, Handfield Jones, Ringer, Balthazar Foster, Franks, Wood, Lauder Brunton, Milner Fothergill, and others—have shown its mode of action: that it so influences the cardiac ganglia as to induce a more perfect contraction of the ventricular muscle, and hence a more complete emptying of the ventricles; whilst at the same time, by an action of the vaso-motor centre, it causes contraction of the arterioles and a heightened tension in the arterial system. It slows the heart by lengthening the diastolic pause. So not only does it give rest to the wearied cardiac muscle, but—as this muscle is nourished only during such diastolic pause by the blood which then enters through the coronary arteries—it directly ministers to its nutrition. It is a matter of common experience that digitalis, especially when combined with iron, strychnine, cod-liver oil, and other tonics, restores the *status quo ut ante* when in a patient manifesting a mitral systolic murmur the evidence indicates that compensation is beginning to fail. As, however, with every other medicinal agent, caution must be used in the administration. As regards dosage, a certain golden mean has to be observed. The often-repeated maxim concerning the middle way points its lesson again—

“*Levis alit flammam; grandior aura nocet.*”

A little over a suitable dose may induce nausea, vomiting, irregularity of pulse, and, instead of slowing, an enhanced rapidity of heart's action; whilst a dose which produces a favourable result is constant and discoverable in regard to a large majority of patients in a minority such dose is inconstant, and even unattainable.

As regards the preparation used, we may have differences of result, and we know that, as in the case of so many vegetable preparations, the energy of different samples may vary. The pharmacopœical equivalents of the official drugs P.B. are a little awkward: One grain of the dried and powdered leaves = one-third of an ounce of the infusion = eight minims of the tincture. Practically I consider the tincture most reliable, and that usually in small doses (℥v. to ℥x., increased only in exceptional cases, and then occasionally reduced); next in value I consider the powdered leaves (gr. $\frac{1}{4}$ ad gr. ij.).

In some cases, even by increasing the dose, no apparent influence appears to be exerted by the drug. Then digitaline,

especially when hypodermically injected, I have observed to give in many cases good results. Digitaline hitherto prepared has probably scarcely ever been the pure alkaloid, but it appears likely that by a new process it can be obtained in a state of purity. The dose for hypodermic administration is 1-50th of a grain. In a child of ten years of age suffering with dropsy and great distress from mitral regurgitation I have found after injection of 1-100th of a grain of digitaline hypodermically, administered at intervals of four hours, the pulse-rate reduced by 8 per minute after each injection. In this case recovery took place from the urgent symptoms, and the child was sent to a convalescent home. She relapsed, however, and died three months afterwards, when away from our observation.

When the right ventricle has dilated so far that there is marked tricuspid regurgitation the beneficial action of digitalis is by no means so decided. Nevertheless, in some cases, especially when occasional purgation is a part of the plan of treatment, the signs of tricuspid regurgitation may pass away. For instance, in a child (Alice B.), aged 11, under my care at the North-Eastern Hospital for Children, mitral regurgitation with dropsy was manifested, and marked venous pulse was seen in the left external jugular. Treatment consisted of 6-minim doses of tincture of digitalis three times a day. The child had taken previously as out-patient 4-minim doses, with 4 grains of ammonio-citrate of iron, three times a day. After 21 days all severe symptoms had passed away, there was no venous pulse, and the case was discharged as convalescent two days afterwards.

In other cases no such favourable result attends. In fact, as *a priori* considerations might suggest increased force of systole which the digitalis may bring about serves to urge back the blood through the imperfect tricuspid orifice into the venous channels. But then, I have seen good results when the administration of digitalis has been combined with abstraction of blood by leeches or cupping. In a child of 10 (Maria W.), manifesting mitral and tricuspid murmurs with pericardium, evidence of greatly dilated right ventricle, after rest in hospital for a fortnight and administration of tincture of digitalis in 4-minim doses, with tincture of the perchloride of iron (℥x.), and a single leech applied to the epigastrium every other day for 14 days, it was noted that the dulness over the right cavities receded to the mid-sternal line coincidently with general signs of amendment. I prefer very small abstractions of blood repeated every two or three days to larger bleedings at longer intervals. In a case lately under my care at the London Hospital this lesson seemed to be pointed, though the recovery was very satisfactory:—

Alice F., aged 11, was under my care for mitral and tricuspid regurgitation, with great and advancing œdem, orthopœnia, and cardiac distress. She was treated by 20-minim doses of tincture of perchloride of iron with 5 minims of tincture of digitalis. After twenty days tincture of cascra was substituted for digitalis, with no apparent benefit. Digitalis was then resumed as before, and considering the great distension of the right chambers, 6 leeches were applied to the chest. Great relief of dyspœnia followed, and œdema became less. Improvement was maintained for ten days, and then urgent dyspœnia and signs of greater dilatation of right chambers occurred. Cascra was again tried, and this time with some apparent benefit. Purgatives (pulv. jalapæ co., ℥ss.) were also administered, but still these grave signs of right ventricle engorgement continued. Again, 6 leeches were applied to the præcordia. A few days afterwards a great vein trunk in the right upper arm was found to be plugged, and the whole arm and forearm enormously swollen. It seemed to me possible that the abstraction of blood, by rendering coagulation more easy, had disposed to the thrombosis. Nevertheless, I was convinced that the cardiac trouble was sensibly relieved by the leeching, and this was repeated, and saline diuretics and digitalis again administered, in doses increasing from ℥v. (vj.), ix., x., and xx.). Under this treatment there was gradual, but very marked improvement. After five days of the full dose of digitalis it was altogether omitted for ten days, and then resumed in ℥x. doses. All the urgent symptoms passed away, the enormous swelling of the arm due to the venous thrombosis entirely subsided, and the patient was discharged convalescent and able to walk with comfort, after having been in hospital for six months.

2. *Belladonna* is, I think, only useful in the treatment of failure of compensation in cases of mitral regurgitation when combined with, or occasionally substituted for, digitalis. *Belladonna*, like digitalis, increases the power of systole, and

(a) “The Heart and its Diseases, with their Treatment.” Second edition, chap. v., p. 96. London: H. K. Lewis. 1879.

raises the arterial tension. As Dr. Lauder Brunton has shown, it paralyzes the cardiac terminals of the vagus, and reduces irritability by an anæsthetic effect on the sensory nerves of the heart. Very useful occasionally, it by no means compares with digitalis for prolonged employment. The hypodermic employment of digitaline 1-50th gr. with atropia 1-60 gr. I have found very satisfactory.

3. *Casca*, a tincture made from the bark of *Erythrophloeum Guineense*, the ordeal bark of West Africa, has been employed as a substitute for digitalis. Dr. Lauder Brunton, in his Gulstonian Lectures for 1877, published the results of his elaborate experiments as to its physiological action. In kind this action appears much to resemble that of digitalis. Dr. Brunton has said "Digitalis has hitherto been our great resort in mitral disease, but I think it probable that in *casca* we possess a drug more powerful still; at least, its effect upon the arterioles appears to be greater than that of digitalis, and it is quite possible that it may succeed in those cases of advanced mitral disease where digitalis fails." I have myself employed the tincture of *casca* substitutively for digitalis in a considerable number of cases, but I have never yet been able to convince myself that it has any more beneficial action in mitral disease.

4. *Caffeine*.—Gubler, Shapter, Leech, Milliken, Brakenridge, Huchard, and others have recorded observations showing the beneficial action of caffeine (or its citrate) in cases of cardiac disease, especially where dropsy is a marked symptom. Some of the cases show very forcibly that a favourable influence has been exerted by the drug. There are many apparently contradictory data as to its physiological action, but the cardinal points are that it first quickens, but soon after slows, the heart's action; that it increases the general arterial tension; and acts in a very pronounced manner as a diuretic in cardiac dropsy. Dr. Brakenridge advises that digitalis be administered previously to, or in conjunction with, the citrate of caffeine, and that small doses (gr. iij.) should be employed. (a) M. Huchard, however, recommends that caffeine, and not its citrate, should be used, and that in larger doses (gr. iv. to gr. v.). (b) It produces diuresis more rapidly than digitalis, and has none of its nauseating effect. I have employed citrate of caffeine in substitution for digitalis, and without any marked benefit being manifest; indeed, I have found that in some cases it has induced insomnia. Nevertheless, I consider that the evidence is such that I should certainly employ it in any case where, in cardiac dropsy, a rapid diuretic effect was desirable.

5. *Convallaria Majalis*.—This is the well-known lily of the valley, long employed by the Russian peasantry as a remedy for dropsy. It is, botanically, closely allied to asparagus, the diuretic effect of which is well-known. M. Germain Sée has made a series of researches which point to it as probably a valuable agent in the treatment of failure of compensation in cardiac disease. (c) The preparation used is an extract of the whole plant, flowers, stems and roots. The mode of action of the extract of *convallaria* also resembles that of digitalis—it slows the heart whilst increasing the force of systole, and augments arterial tension. It is said that it does not, like digitalis, exhaust the contractility of the heart and arteries. Administered in doses of 15 to 22½ grains during the day it has apparently produced very favourable results. M. Sée has recorded five cases of mitral regurgitation in which it was employed. It entirely relieved the œdema and cardiac distress, and manifested a pronounced diuretic action. I am now employing the extract of *Convallaria* in mitral disease in 5 grain doses. I am convinced of its power of raising the intra-vascular pressure, and of its increasing the force of systole, but I am not yet convinced of its superiority to digitalis. The results, however, are such as to warrant an extended trial. I shall have to speak of it again in regard to the treatment of aortic disease.

6. *Morphia*.—Judiciously employed, I consider that this is one of the most valuable of agents, or rather adjuncts, in the treatment of the distress, especially the dyspnoea and insomnia, attendant upon failure of compensation in cases of mitral regurgitation. I am strongly of opinion that it should not be administered by the mouth, but by hypodermic in-

jection. When given by the mouth, it disagrees, just as opium frequently does, whereas, administered hypodermically, it calms the most distressing dyspnoea, without inducing, so far as my experience goes, any ill effect. The value of the hypodermic use of morphia in the distress of heart disease, was brought before the profession, in his usual forcible and able way, by Dr. Clifford Allbutt in 1869. (a) I entirely endorse his view of the value of this remedy and its innocuousness in cardiac failure. I have found it valuable to combine the morphia (usually a hypodermic dose of one-third of a grain) with atropine (gr. 1-60th), or digitaline (1-50 gr.), but the morphia is an essential agent in the successful treatment of mitral regurgitation, when there is much respiratory distress.

Coincidentally with such special cardiac treatment, general measures should be adopted for securing improved nutrition. The heart-muscle must not only be preserved from wasting, but it must be fed. The problem of administering a due amount of nourishment is often a difficult one. Dr. F. J. Roberts has recommenced in the gastric crises of cardiac disease, when there is an almost complete inability to take food, the use of peptonised aliment in a sipping fashion. This plan I would combine with the administration of nutritive enemata, as I have before mentioned. I feel sure, from my experience, that lives may be prolonged and crises tided over by such supplementary alimentation.

The foregoing is a brief sketch of the most important agents now at our disposal for restoring the power of the heart-muscle and inducing due compensation in mitral regurgitation, occasioned by rheumatic endocarditis, when failure threatens. The restoration of such compensation may not, however, be the only indication. Accidents of the disease, so closely related therewith as to force the necessity of considering them in any question of prognosis and treatment, demand consideration. Such epiphenomena are renewed attacks of endocarditis, pericarditis, especially when accompanied by myocarditis and adhesions and embolism. These subjects, however, being equally manifest in mitral stenosis and mitral regurgitation, may be conveniently postponed till the next lecture.

V. There is, however, yet another group of cases of mitral regurgitation to consider. In these, there is no history of antecedent rheumatism, the modes of causation we have hitherto discussed are excluded, the condition has arisen gradually in association with conditions of high tension in the arterial system. The differentiation of this class of cases is important, both for prognosis and treatment. A considerable minority of cases manifesting regurgitation come to us with no history whatever of rheumatism. I calculate from the hospital records that these are about one-fourth of all the cases. I have said, however, in my former lecture, that rheumatic endocarditis may be established without other evidence of rheumatism: it is obvious, therefore, that such cases of insidious endocarditis inducing mitral insufficiency may be included in the minority we are considering. The diagnosis between these and the cases of regurgitation due to yielding of the ventricle from intra-arterial pressure may generally be arrived at without difficulty. In the latter, the signs are those of hypertrophy rather than dilatation of the left ventricle. The aortic second sound, if there be no evidence of aortic disease is pronounced whilst (the amount of blood regurgitating being small), the pulmonary second sound is not accentuated. The arterial pulse is strong and incompressible, and the arteries are often tortuous and visibly atheromatous. It is obvious that these signs are very different from those usually met with in the rheumatic cases. Very important evidence is afforded by the sphygmograph, the pulse trace showing in the non-rheumatic cases an ample tidal wave, and the usual evidences of high arterial tension. Such cases are often associated with gout or with chronic renal disease.

In their treatment I have known no plan so successful as a protracted course of alkalies with abstinence from alcohol, and as much rest as can be procured. Digitalis is not contra-indicated, notwithstanding the general high-pressure in the arteries. I have found it of much service, probably by co-ordinating heart and arteries. In any of the accidents of high tension, such as symptoms of angina or dyspnoea occurring in this class of patients, the administration of nitro-glycerine, or the inhalation of nitrite of amyl is of much service.

RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S. Eng., M.S. Lond.,
Surgeon to the London Hospital.

PART II.—*Reported Cases of Recovery—Treatment—Conclusion.*

(Continued from page 72.)

NOTWITHSTANDING the freedom with which I have criticised the records of the reported recoveries after intra-peritoneal rupture of the bladder, I would gladly see all objections to their genuineness satisfactorily overcome, and obtain an assurance that the lesion is not beyond the possibility of spontaneous recovery, or the simplest resources of our art. In reply it may, of course, be urged that the very fact of recovery would at once excite antagonism, and cause the case to be rejected, unless the rent had been demonstrated beyond dispute. I do not think that this would be so if the evidence of distension of the bladder, injury to the hypogastric region, and of the typical symptoms, was really clear and satisfactory. It is because, on comparison with the records of indubitable cases, the reported cases of recovery are found wanting in the most essential particulars, and admit of a more probable solution, that they have to be set aside in spite of a sincere desire to welcome success as a gain both to humanity and surgery. Even in respect to Dr. Walter's case, which I am anxious to admit as an indubitable instance of recovery, I am obliged to suspend my judgment until I have before me a full report of the primary history, and have some reasonable scruples dispelled. But apart from the objections which can be urged against the genuineness of the recorded recoveries after intra-peritoneal rupture of the bladder, there is one circumstance which would quite justify us in setting the cases on one side in considering the question of *treatment*. That circumstance is the remarkable fact that if the genuineness of all the eight cases were to be admitted, the effect in regard to the selection of the best method of treatment would be thoroughly bewildering. The record would show four cases of recovery after the use of the catheter only; one case of recovery after "washing out the peritoneal cavity" by means of the catheter passed through the rent in the bladder; one case successfully treated with the aspirator; one case of recovery after lateral lithotomy; and one case of recovery after abdominal section, sponging the urine and blood from the peritoneal cavity, leaving the rent to itself, and retaining (!) a catheter in the bladder. The inference would be drawn that one mode of treatment is as good as another, and this "lame and impotent conclusion" would sadly mar the prospect of attaining an effectual means of dealing with a most fatal lesion.

Turning, then, to the accounts of the cases which are beyond the reach of doubt, we may affirm that in neither form of rupture—the intra-peritoneal or the extra-peritoneal—can reliance be placed on constitutional and general means of treatment. Leeches, venesection, fomentations, clysters, purgatives, sinapisms, salines, poultices, calomel, opium, morphia, &c., probably affect the ultimate issue as little as the fresh sheepskins applied to the abdomen of the patient whose case is reported by Bonetus, and the oxryrhodium with which the parts were subsequently smeared. Morphia and opium may be very efficacious in relieving suffering, but uncombined with surgical measures they have no power to do more than promote the euthanasia. If any hope is to be entertained it dawns in the prompt application of efficient local treatment. The main indications are two—first, the removal, as speedily as possible, of the effused urine, and secondly, the prevention of the further escape of urine through the rent in the bladder into the connective tissue or the peritoneal cavity. For these purposes the means at the disposal of the surgeon are catheterism—intermittent or per-

manent—washing out the peritoneal cavity and retaining a catheter in the bladder, paracentesis abdominis, or simple incision to evacuate the urine, perineal sections—median or lateral—as for stone in the bladder, tapping the recto-vesical *cul de sac*, and abdominal section, combined or not with sewing up the wound in the bladder and the establishment of drainage. Let me briefly review the advantages and disadvantages of each.

1. By the use of the *catheter* only it is possible to draw off a considerable proportion of the urine effused into the peritoneal cavity, provided that the rent happens to be in the posterior wall of the bladder, but it will not remove all of it; and when the rent is in another part of the viscus it may fail to remove any, whether from the peritoneum or connective tissue. If passed only at frequent intervals it will not altogether prevent further extravasation, and is liable to disturb the process of repair. Retention of a catheter in the bladder is more efficacious in preventing effusion, but it is not thoroughly reliable, and the patient, finding it intolerable, may remove the instrument in the absence of the medical attendant. It is no wonder, then, that, as catheterism alone does not fulfil the necessary indications, it should have been "weighed in the balance and found wanting." For retention in the bladder the india-rubber catheter will be the best and the most comfortable for the patient.

2. *Washing out the peritoneal cavity*—as in Thorp's case it was euphemistically termed—by means of a catheter fitted with an india-rubber bag and stop-cock, has been strongly recommended by Mr. Heath on the basis of its supposed success in the hands of Dr. Thorp, and the failure of abdominal section in his own and Mr. Willett's cases. Mr. Heath says, "It seems to me to offer as good, if not better, chances of success than any other proceeding, and has the great advantage that it can be put in action promptly, which is, after all, the great point. In addition, it introduces no new element of danger to the patient, nor any serious surgical proceeding which may be distasteful to his friends." As this method has not been adopted in any other case but Dr. Thorp's, it would be premature to pronounce any positive opinion on its merits; but if the friends objected or the patient objected to an operation, it might be tried with such modifications as experience may suggest. I cannot say that I entertain any well-grounded hope that it will prove efficacious in removing the extravasated urine or neutralising its evil effects, for it appears to me to be a fallacy to suppose that the complicated peritoneal cavity can be washed out, as a simple circumscribed cavity like the bladder can be washed out, through a catheter alone. For effectual washing out an opening should be established into the peritoneum above the pubes, whereby the danger of merely driving the urine further amongst the intestinal coils could be obviated. Certainly such a will-o'-the-wisp as Dr. Thorp's case should not lead the surgeon astray from the employment of more active measures when he is at liberty to act as his judgment directs. For washing out a solution of thymol would be better than warm water.

3. *Tapping the recto-vesical cul de sac* was suggested by Dr. Harrison as a means of treating intra-peritoneal ruptures under the mistaken impression that the urine frequently collects and is confined in that pouch, and that a dependent opening into the rectum would efficiently drain the peritoneal cavity. In speaking of this measure Mr. Spence pertinently observed: "The state of parts in my own case showed me that the operation of puncturing the inferior *cul de sac* of the peritoneum to evacuate urine supposed to be lodged in the peritoneal cavity must always be uncertain, and often dangerous; whilst, as the fluid is diffused, it would not be fully drawn off, and this can only be possible in those very rare cases where the urine has accumulated, and is limited by adhesions, a condition of the existence of which I am very sceptical."

4. *Paracentesis abdominis* has been performed twice in intra-peritoneal ruptures. In the case observed by Dr. Spon, and reported by Bonetus, "paracentesis was performed by the hand of a skilled operator four fingers breadth from the umbilicus at the part which slopes towards the right side" (right iliac region). "Six ounces of fluid blood leapt from the wound. The patient was in no wise benefited by the operation." Mr. Cusack used a lancet and director in one of his cases. A considerable quantity of urine was evacuated both at the time and some hours after the incision. An ordinary trocar and cannula, or an aspirating needle and cannula, might be employed, care being taken not to wound intestine. Paracentesis has not been practised often enough to warrant a decisive judgment. Performed with a cutting instrument, it appears to be more efficient for the removal of effused urine than the catheter or tapping the peritoneal cavity through the rectum, and much safer than the latter operation. It might be practised for the confirmation of a doubtful diagnosis as a preliminary to abdominal section, or as a substitute for it, when a more effectual procedure was forbidden. In extra-peritoneal ruptures incision through the anterior abdominal wall above the pubes is indicated when the rupture is in the anterior part of the bladder. In the case which occurred at St. George's Hospital, and survived for forty-three days, a vertical incision drew off a collection of urine from behind the symphysis pubis. In Allin's case (a) an incision two inches long in the *linea alba*, close above the symphysis, drew off three pints of urine. In Delagarde's case (b) an incision was made above the pubes, evacuating urine, and drainage tubes were passed into the pelvis. The bladder was kept empty by means of a flexible catheter. Sloughing occurred, and the obturator vein was implicated. Recurring venous hæmorrhage caused the loss of several pints of blood, and death occurred from exhaustion. Incisions must be made also wherever there appears to be a collection of urine.

5. The operations of median and lateral lithotomy, or cystotomy, are of unequal value. The median operation consists merely of urethrotomy and dilatation of the prostatic urethra and orifice of the bladder, and as the sphincter soon regains its retentive power, can scarcely be effectual either for the removal of urine already in the peritoneal cavity, or for subsequent drainage. For exploration it would be simple, safe, and valuable; and in cases complicated by stricture, the best method of preliminary procedure. In his case of rupture following stricture, Mr. Henry Arnott tapped the bladder *per rectum*, and drew off five ounces of bloody urine. In the case at St. George's Hospital above referred to, perineal section was performed because the catheter could not be passed. In Clark's case the bladder was cut into through the perineum, evacuating a large amount of blood and urine, to the great relief of the patient. Although he had been caught between two heavy timbers, and had sustained multiple fractures of the rami of the pubes and ischium, as well as a rupture of the bladder, the patient survived twenty-five days. In Dr. Chamber's (c) case the urethra was ruptured as well as the bladder, which was torn in two places. Free incisions were made into the scrotum and perineum, and the urethra was laid open on a lithotomy staff. Urine and blood escaped, and a catheter was introduced through the wound. In Earle's case, which was complicated with separation of the pubic and sacro-iliac symphyses and rupture of the rectum, and in which the bladder was torn away from the prostate, perineal section was performed, and the finger introduced into the bladder. Death took place in forty hours. Perineal section was also performed in Mr. Quain's case, which was complicated with separation of the pubic and sacro-iliac symphyses and laceration of the membranous

urethra and muscles of the thigh. Blood and urine were emitted. Mr. Reginald Harrison (a) made a median perineal incision with advantage in a fatal case of injury to the bladder and prostate. Urine had escaped through a laceration, passing through the base of the bladder. Dr. Erskine Mason refers to the case of a middle aged man caught between a ferry-boat and bridge. In addition to a rupture of the bladder, the man sustained a fracture of the pubic bones, which projected through the anterior abdominal wall. The median operation was performed by Dr. Robert F. Weir, but the man died. Dr. Erskine Mason quotes the case in illustration of the disadvantage of the median operation, as the bladder soon regains the power of holding water. In lateral cystotomy, on the other hand, the knife would be able to cut freely into the prostate, and reach the neck of the bladder, which would be slow to regain its retentive power. This constitutes the great recommendation of the lateral operation, and no other measure appears to me to equal it for efficiency in this important direction. By itself it could scarcely have much effect in removing urine already effused into the pelvic cavity, and for this purpose some supplementary procedure would be necessary. It is also difficult to understand how the operation could be effectual for the removal of urine which had already escaped into the pelvic fascia through an extra-peritoneal rent; but probably it might answer the purpose for extra-peritoneal ruptures immediately behind the prostate, if the operator had the boldness to carry his incision through the gland and its capsule. In a case of intra-peritoneal rupture Mr. Partridge cut into the bladder and found it empty. The procedure has been strongly advocated by Dr. Stephen Smith and Dr. John A. Liddell (b) in America, and Mr. Bryant in England.

To be continued.

AN ESSAY UPON HIP-JOINT DISEASE.

By S. D. CLIPPINGDALE, M.D., F.R.C.S.

(Continued from page 72.)

V.—THE SYMPTOMS.

FOR the convenience of examination and description of symptoms, hip-joint disease may be divided into three stages, with clinical features characteristic of each. Dr. Davis, of New York, ridicules the idea of division of this affection into stages, and thinks we might speak with equal propriety of the first, second, and third stages of a burning house." (c) It is clear, however, that the rupture of a capsular ligament marks a distinct change in a case of joint disease, and it is to be presumed that before the capsular ligament ruptures the joint is full of fluid, and that at a period antecedent to this the joint contains no fluid at all. A case may, therefore, reasonably be described as having a stage prior to effusion, a stage of effusion ending either in absorption of the fluid or rupture of the capsule, and lastly, a stage following rupture of the capsule. In the first stage the synovial membrane is in a state of active inflammation, hyperæmic from distension of vessels, all movements causing pain, and the patient feverish. In the second stage the synovitis has increased, and the joint distended with fluid, which is either synovia, pus, serum, or a mixture of these. In this stage there are all the local signs of a distended joint, and all the constitutional effects of continued fever. In the third stage, the capsule having ruptured, the contained fluid escapes into various tissues, damaging these; and within the joint, the cartilages, and later, the bones suffer from exposure to the inflammatory action; while the constitution exhibits the effects upon it of prolonged

confinement to bed and continued disease. The symptoms, therefore, may be reasonably classified and described in three stages.

Symptoms of the First, or Pre-effusive Stage.—These are mainly—1, local tenderness or pain; 2, alteration in posture or gait; 3, increase in local temperature; 4, constitutional changes.

1. *Local Pain or Tenderness.*—An inflamed synovial membrane produces great pain, and this is increased if the inflamed membrane be compressed or moved. In the earliest stage, therefore, of hip-disease, the patient generally complains of pain or tenderness about the joint, increased when the inflamed surfaces are rubbed against one another, as when the joint is moved, and also when they are brought into violent contact, as by tapping the heel or knee. Pain in the knee in this, the pre-effusive stage, is, in my opinion, rare, and in the proper place I shall endeavour to show that this symptom is dependent upon a distended capsule.

2. *Alteration in Posture and Gait.*—To lessen friction in walking, and pressure in standing, the patient touches the ground with only the toes, or the anterior half of his foot, and does not plant the whole of it firmly on the ground. By so doing the knee and hip are both flexed. This flexion produces vertical shortening of the extremity. To compensate for this shortening, the pelvis is lowered upon the affected side, and "apparent lengthening" is produced; that this is apparent, and not real, is shown by measurement. As a result of the lowering of the pelvis on the affected side, the spine takes on a compensatory curvature to keep the head and trunk erect.

3. *Local Heat.*—There is in most cases a rise in temperature around the joint, but its estimation requires considerable care. Mr. Macnamara, who has taken some pains to examine this condition, uses a Dupré's surface thermometer, and finds that there is generally an increase of one, two, or three degrees.

4. *Constitutional Disturbance.*—In the earliest stage of hip-disease the constitutional symptoms are principally listlessness, loss of appetite, sleeplessness, thirst, &c. Until attention has been attracted to the local cause for these symptoms much misconception may arise, and a child with incipient morbus coxæ has been regarded as suffering from "growing pains," or "worms," or "bad temper," and appropriately treated.

Symptoms of the Second Stage (Stage of Effusion).—In this stage there is continuation, with aggravation of the symptoms of the first stage, to which are added those due to the collection within the joint of a gradually increasing quantity of fluid. The symptoms, therefore, special to the second stage are local swelling and pressure symptoms.

1. *Local Swelling.*—This, as might be supposed, is extremely difficult to detect at its onset, yet much may be done by careful examination. If the patient be laid flat upon a couch a difference in the two hips, more or less distinct, will be observed, and verified by manual examination. One of the best methods for detection of fluid in the joint is to palpate with the fingers of one hand in front of the joint, and with the fingers of the other behind the great trochanter. If the patient be thin, slight distension may in this way be detected, and if effusion be considerable its discovery is easy. Mr. Barwell recommends the following method, which he practises, he says, with considerable success. The thumb of one hand is placed in the subpubic fossa, that is, just behind the origin of the adductor longus, and the fingers of the same hand are placed just behind the great trochanter. By pressure between thumb and fingers the surgeon can detect swelling by marked and unmistakable signs. In making this examination the surgeon should place himself directly in front of his patient, and examine both hips at the same time.

2. *Pressure Symptoms.*—By the pressure of the dis-

tended capsule upon the vessels and nerves definite symptoms are produced. The effects upon the arteries is to lessen the vigour of the pulse in the ham, and at the ankle, and the surface veins become distinct, and œdema may follow. Pressure upon the nerves produces pain of a neuralgic character, which may be felt wherever the nerves are distributed. One pain peculiar to this disease, namely, pain at the inner side of the knee, deserves especial examination and description.

Pain in the Knee.—Many and various opinions have been, and still are held, as to the cause of this characteristic pain. Prior to the publication by Sir Charles Bell (a) of his views, the general belief was that this pain was due to irritation of the anterior crural nerve. Sir C. Bell, however, originated the opinion which has since been generally held, that the obturator nerve was the nerve through which pain was transmitted, irritation of the articular branch of this nerve by the joint disease causing pain to be felt by reflection in that branch going to the inner side of the knee. Ford, a great authority, in his work upon hip disease, published 1794, mentions this symptom without speculating as to its cause. Chelius does not mention it. Coulson, referring to Sir C. Bell's opinion, says, "This explanation is not of itself sufficient to account for the symptom, for we very commonly find the pain extending along the middle, and even in the outer part of the thigh. It has struck me," he adds, "that from the intimate character of the long head of the rectus femoris with the outer edge of the acetabulum, and with the capsular ligament, the fascia of this muscle may take on the inflammatory action, and the pain in this way may be conveyed down the limb to the thigh" (knee?). Another authority, Richet, thought the pain due to irritation transmitted along the medullary canal of the femur from its upper to its lower end. Bonnet thought that a strain upon the ligaments from malformation would cause it; while Stromeyer attributes it to strain upon the iliacus and psoas muscles. Barwell considers that in some cases this knee pain may be caused by muscular spasm. The same author, and with him the writers Walthar and Fricke, think the pain may also be caused by a sympathy between the two ends of the bone. Hilton, Macnamara, Erichsen, and other modern authorities support the view of Sir C. Bell, that the pain is reflected from one branch to the other of the obturator or accessory obturator nerve.

I would venture to assert, however, that this pain is mainly, if not wholly due to the pressure of the distended capsule upon the trunk of the obturator nerve. In support of this view I would point out that, whereas the hip-joint is supplied by many nerves, the pain is felt in connection with only one. Now if it were due to reflection we should expect to find it reflected by all of them. In ascertaining why the obturator nerve alone should cause this pain we discover that in its passage from the pelvis it passes very closely to the under part of the capsule of the joint. At this particular part the capsule is unsupported by any cotyloid cartilage, whose continuity is here broken by the cotyloid notch, and when the capsule is distended by fluid it would of course bulge into this notch, and so press upon the obturator nerve passing beneath. This view as to the causation of the knee pain seems to me to be supported by clinical evidence, for it is present only when there are signs of joint distension; and Ford, who was unable to account for the pain, noticed that it always disappeared when the limb became shortened, that is, when dislocation occurred after rupture of the capsule and escape of its contents; and "continued as long as the diseased limb was longer than the sound one" that is, while the femur was thrust downwards by a distended capsule. I would therefore hold that this peculiar pain will be found to begin with distension of the joint capsule, continue as

(a) London Medical Gazette, vol. 1.

long as that distension lasts, and terminate with either the liberation or the absorption of the fluid, and that the knee pain is caused in the great majority of cases by the simple pressure of the distended capsule upon the trunk of the obturator nerve.

Clinical Records.

WEST LONDON HOSPITAL.

Case of Glossitis—Treatment by Calomel.

Under the care of Dr. THOROWGOOD.

House Physician, Dr. SCHACHT.

WILLIAM P., stableman, æt. 35, admitted under Dr. Thorowgood, November 9th, 1882. Patient can assign no cause of present illness; is not aware of exposure to any source of contagion in his occupation among horses.

November 9th.—On admission he is scarcely able to open his mouth sufficiently to allow of a good view of the tongue, but this organ can be made out as much swelled, and coated with thick milky mucus, which runs out between the teeth. One side of the tongue looks yellowish, but the rest of the organ is dark and congested. Voice is weak and nasal, and power of swallowing limited to liquids only. Temperature, 103°. The patient was ordered a powder of

Hydrarg. subchlorid, gr. ¼;
Sacc. albi., gr. iij. M. 4tis. horis.

And a gargle of ℥ij. of glycerine of borax in ℥vj. of water.

13th.—Temperature normal, and patient able to eat a thick piece of bread and butter. To omit powders, and take a mixture with chlorate of potash and tincture of perchloride of iron.

16th.—Able to leave perfectly cured.

Remarks by Dr. Thorowgood.—The condition of the patient on admission, though not dangerous, was one of acute discomfort. The parotid and submaxillary glands were tender, but not very much swelled; and it seemed to be the state of the enlarged tongue that prevented his opening his mouth or taking solid food. No ulceration could be made out, and there was not at any time any purulent discharge. The nature of the man's employment among horses, the nasal tone of his voice, and the yellow patch seen at one side of the tongue, suggested the possibility of glanders; but there was no eruption about the lips, and the constitutional depression was not marked. With regard to treatment, it was clearly important speedily to arrest the swelling, and, with a view to promoting secretion from the various glandular structures, calomel was given in powder with sugar. To this treatment the disease soon yielded, with rapid fall of temperature. Similar cases of glossitis have done well under treatment with iodide of potassium—a salt which, like mercury, acts as a promoter of secretion from the salivary and buccal glands.

CASE OF COMPLETE INVERSION OF THE UTERUS, PRODUCED BY A MIDWIFE.

Under the care of Dr. W. HASTINGS BURROUGHS,
Paris.

I was called lately to a case of complete inversion of the uterus, produced by an ignorant midwife drawing on the cord. Upon arrival I found the woman in an unconscious state—pale, cold, and with a quick, thready pulse. The uterus was between the thighs, of the volume of a child's head, and the placenta was adherent. Blood was oozing from the corrugated walls of the womb in abundance, and the perinæum was torn to within a half-an-inch of the anus. Before attempting reduction, the placenta was detached by the fingers as well as possible, and then the womb was pushed into the vagina, where the reduction, after much difficulty, took place. The patient did not recover consciousness for three hours, and although the uterus suffered much from manipulation, the metritis that succeeded was but very slight. Ergotine and quinine were given, with injections of phenicated water, and the pulse never went beyond 120.

On the third week following the accident the patient was up and about. From first to last there was not a bad symptom. A fortnight after the occurrence, a speculum examination was made, when the uterus was found well in position,

but the os was considerably congested, and there was abundant leucorrhœa. Astringent injections were ordered, and in ten days the uterus assumed its normal appearance, although there was a tendency to prolapsus, which probably will remain.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

AUTOPSY ON M. GAMBETTA.—Although the official report on the disease to which M. Gambetta has succumbed is not yet issued by the medical men who attended him, some interesting details are given in *L'Union Médical* from the pen of one of the surgeons who was consulted by the illustrious statesman in his last malady. On the 13th December, sixteen days after receiving the pistol wound, and after a copious repast, M. Gambetta experienced a very sharp pain in the inguinal region on the right side, which lasted half an hour, and then gradually disappeared. For several years, it appears, this pain manifested itself frequently, and about an hour after meals, which generally passed off when pressure was made on the part. But this last time the painful sensation did not pass away so quickly, and the part remained sensitive longer. On the 16th M. Gambetta, surrounded by a few friends, remained a little late in the garden, and when he retired he was taken with a shivering which was very pronounced, the temperature rose to 104°, and the abdominal pain became very sharp. Signs of perityphlitis manifested themselves on the following days, and soon the inflammation attained the peritoneum, the iliac fossa became gangrenous, and death supervened the 31st December. At the autopsy, which was made forty-eight hours after death, putrefaction of the liver and kidneys prevented a proper examination of these organs. The peritoneum was slightly inflamed in the region of the ascending colon, in the right hypochondriac region there was subperitoneal inflammation, especially around the large intestine (pericolitis); the biliary vesicle was adherent to the angle of the colon; the same adhesions were discovered between the vermiform appendix and the cæcum, and, what was more important, this last lesion undoubtedly was the one which contributed the most to the fatal *dénouement*; the ileum was found to be constricted about two inches from its termination, and this constriction, which was of old standing, was so narrow that the end of the little finger could not be passed through. The pain that M. Gambetta experienced after meals evidently proceeded from the effort made by the digested aliments to pass from the ileum to the large intestine. Pressure on the part at this moment would have evidently aided the matter to squeeze through; and the ease that generally followed the act was proof of it; and the copious repasts that M. Gambetta generally made, although causing a certain amount of uneasiness, yet must have acted in a salutary manner on the stricture itself, as such an amount of matter passing through once or twice a day must have prevented the constriction from increasing, on the same principle as the sound. But when he was put on a *régime* after the wound in the hand, the stricture gradually narrowed, and constipation having resulted from the prolonged recumbent posture, a collection of matter must have formed above the ring, which had not been subjected to this forced dilatation for several days; hence the more than ordinary acuteness of the pain, which lasted longer because the dilatation was brusque. It is probable that the phlegmon that was discovered a few days afterwards originated in a slight tear in the intestine effected at this moment. The other organs were healthy, and the brain, whose convulsions

were very perfect and symmetrical, did not weigh more than 1160 grammes, which is the weight of an ordinary small brain. However, it is now acknowledged by the best authorities that the development of the intelligence is not necessarily in proportion with the weight of the brain. The conduct of the surgeons who had charge of the case has been variously criticised on account of their expectant attitude, and for not having gone boldly in search of the purulent matter; but, given the state of M. Gambetta's constitution (obesity, albuminuria, &c.), it is very probable that the operation would only have hastened the end.

Special.

OPHTHALMIC NOTES.

AMBLYOPIA, ALCOHOLIC AND TOBACCO.

SINCE Mackenzie first directed attention to the influence of tobacco on vision numerous observations have been made in different countries confirming his views. At the meeting of the British Medical Association, 1879, Dr. Herschberg, Berlin, opened a discussion on this subject. He said that whilst Von Graefe and many of his followers in Germany were drawing out the symptomatic differences between progressive atrophy and benign amblyopia, other observers, and especially Hutchinson and his *confères* in England worked at the natural history of the latter class of affections and established the fact that abstinence from tobacco is followed by cure in most cases. Förster, uniting these two points of view, has given much greater attention to the subject, and shown that tobacco causes a symmetrical defect in the central part of each visual field which accounts for all the symptoms and which disappears partially or entirely when smoking is abandoned.

Herschberg had confirmed and amplified Förster's observations; he maintained that tobacco is the cause of the majority of cases of amblyopia; in a minority of cases alcohol alone appears to be the cause; but the defect of the field in these is thought to be more truly central than in the tobacco cases.

In the discussion on this paper,

Swanzy (Dublin) admitted that tobacco amblyopia was very common among the lower orders in Ireland, as they smoked Limerick twist, a very strong and moist tobacco. He thought the amount of nicotine and other deleterious substances contained in various tobaccos had been lost sight of, explaining the difference of tobacco amblyopia in various countries.

Mr. Walker (Liverpool) said he had repeatedly seen complete blindness result in cases of tobacco amblyopia. For its cure complete abstinence was not enough. Mercurialisation seemed also to be largely employed later on; the neutral sulphate of strychnia might be employed by instillation into the eye.

Mr. Nettleship (London) was of opinion that tobacco amblyopia did exist, but he did not think that alcohol gave rise to an amblyopia similar to that of tobacco. Tobacco never caused complete blindness. He could confirm Förster's observations. He considered total abstinence the only essential point in the treatment.

Nettleship has contributed a very useful paper "On the Diagnosis of Tobacco Amblyopia" to the St. Thomas's Hospital Reports, vol. ix., page 51. In the Royal London Ophthalmic Hospital Reports, p. 45, Dr. W. Berry has a paper on the subject of central amblyopia.

COLOUR-BLINDNESS.

So associated is this with the name of the great English chemist Dalton that the term has now become not only a medical, but a popular name for colour-blindness. A large amount of attention has been paid in the past three years to the subject. It is strange that its national importance has been so long overlooked, considering that Wilson wrote about it in 1835. Lives are dependent on the recognition of the colour of a lamp, both on land and sea, and yet we have not secured compulsory examination of our sailors and railway officials to test their colour sense. The activity of the past year has been great. We have pamphlets and treatise by Holmgren, Jefferies, Herman, Cohn, Kalisher, Wolfe, Michel, Fontenoy, Hugo Magnus, Stilling, Dane, and numerous communications made to our medical societies and journals.

At a meeting of the British Medical Association, August 6, 1879, Dr. H. R. Swanzy very clearly laid down some of the conditions for testing colour-blindness. He said that a good test for the colour sense should fulfil the following desiderata: 1. It should be capable of rapidly detecting the existence and nature of the anomaly; 2. It should make the least possible demand upon the intelligence of the patient; 3. It should render deception, whether intentional or unintentional, impossible—hence, every method which depends upon the correct name being given to a colour is bad; 4. The possibility of any interference of the judgment must be excluded in order that the sensations to be tested alone come into play. The spectroscope employed alone does not answer any of the above requirements, and can only be employed in conjunction with other methods. The method by means of coloured shadows, an application of an old experiment as suggested by Dr. Stilling, is very beautiful, and goes far as an argument in favour of Harvey's theory of perception of colour. Dr. Stilling's pseudo-isochromatic tables have not met with universal favour. They consist of figures and letters in red, and pink upon a brown background. Red and brown appear to the red-green blind as similar colours, consequently in such cases the figures and letters should not be distinguishable. Dana, of Kagiro, has published a table with coloured wool, arranged in rows, which are to be recognised by the persons examined as being composed of similar or of different colours. The method of Professor Holmgren, of Upsala, has received the greatest meed of popularity. It is conducted by means of coloured wools, which are to be sorted according to a system, the two chief tests being by a skein of green and a skein of purple wool. By this means the colour sense of an individual may be tested in the space of a minute or a minute and a-half, while no word need be uttered on either side, and a large roomful of people about to be tested may look on without vitiating the tests.

There is also a method much in use in these countries upon railways, &c.; it consists of a card with four squares, red, green, yellow, and blue, to which the correct names are to be given. This is a bad method, for colour-blind persons are often able to name colours correctly by virtue of a certain brightness which one colour possesses as compared with another. Again, some uneducated people are not familiar with the names of colours, and in this way many people with such a test appear to be colour-blind, when not so. Holmgren, Cohn, Magnus, and Joy Jefferies have been the principal observers; as to the frequency of colour-blindness Donders, Fontenoy, and others have also examined large numbers. The percentages given by these observers were, amongst men, from 2.87 to 6.6. Amongst women, colour-blindness is extremely rare, the highest percentage given to them by Dr. Nunder is 1.3. Cohn, in 1,061 females, did not find one colour-blind; Magnus

only 1 in 2,216; and Joy Jefferies in 7,942, only 4. Mr. Swamy had examined 1,320 persons by Holmgren's method: of these 90 were women, and none were colour-blind. Of the 1,230 males he examined, 82 were more or less colour-blind, being a percentage of 6.6. (a)

Wolfe (Glasgow) has published a pamphlet giving the results of an inquiry by himself, Dr. Cummins, and Dr. Pickering. The results of the Glasgow Commission showed that there are 3 per cent. colour-blind, whilst 6.5 per cent. see colours with difficulty.

Hirschberg and Nettleship consider Holmgren's test the best.

Mr. E. Chevreuil has proposed spinning discs as tests for colour-blindness, on the following principle: If a circle one diametrical half of which is painted with any colour (A), and the other half left white, be made to revolve at a speed between sixty and one hundred and sixty turns per minute, the complimentary colour of A appears on the white half.

COLOUR-BLINDNESS AND THE MEDICAL PROFESSION.

Herbert Page (*Brit. Med. Journ.*, October 25, 1879) proposed the examination of the British Medical Association at Cambridge in 1880. This was done, with the following results:—In 700 members twelve were completely colour-blind, six green blind, and six red blind, and two were incompletely colour blind—one red and one green. Four were feeble in their chromatic sense. Joy Jefferies had previously examined 465 physicians, of whom fourteen were red blind, two green blind, and six incompletely colour blind. Joy Jefferies insists upon the necessity of testing a large number of people. He believes 4 per cent. would be found to be the result.

Favre (Lyons), out of 10,000 males, found that 10 per cent. were incapable of distinguishing one or several of the five elementary colours, two were Daltonian's, and eight suffered from chromatopseudopsia.

One of the most valuable communications (at the Cambridge meeting, 1880) was made by Professor Donders, embracing the theory of colour perception, methods of testing, &c. Few have more profoundly studied the colour sense, and he exhibited an apparatus designed by himself. This paper should be read in full.

Transactions of Societies.

YORK MEDICAL SOCIETY.

A MEETING of this Society was held on January 18, Mr. W. H. JALLAND, F.R.C.S., President, in the chair.

Mr. SPENCER read notes of "A Case of Croup, in which Tracheotomy was performed; the child did well for three days, when Broncho-pneumonia commenced, and rapidly proved fatal."

Mr. JEFFERSON read a paper

ON SOME OF THE USES OF PLASTER OF PARIS IN SURGERY. After drawing attention to a few practical points in the preparation of plaster splints, such as the warming of dry plaster, the use of tiffany bandages, and of strips of Bavarian flannel, the latter covered on both sides with moist plaster for the purpose of giving additional strength, Mr. Jefferson said that the plaster splint was to be preferred to the glue, starch, and others in the treatment of fractures, because it dries and sets quickly, thus securing immobility within a few minutes of its application. This splint was invaluable in fractures of the lower extremities and in all compound fractures. Ununited fracture of the humerus was probably best treated by the same splint carried from the hand to the axilla, the arm being kept extended. In simple fracture of the lower extremities,

whether attended with much, little, or no swelling, the plaster splint could always be applied at once. In fracture of the femur, where the hip must be included, some difficulty would be experienced unless something resembling the crane of a hospital bed existed, by which the patient could raise himself. When all swelling had subsided, the splint should be lined with a thick layer of cotton wool, re-applied, and fixed by an ordinary roller. The method of cutting a window in the splint, in the case of compound fracture, was described, with the precautions necessary for rendering and keeping the wound aseptic. With this object, the use of salicylic wool beneath the splint, instead of the ordinary flannel roller, was recommended.

Mr. JEFFERSON also read notes of

TWO CASES OF COMPOUND FRACTURE OF THE UPPER EXTREMITY,

treated at the York County Hospital in the manner described. He also referred to twenty-four cases in which osteotomy had been performed by Mr. Jalland at the County Hospital. None of these latter cases required a second dressing, and at the end of three or four weeks, when the dressings were removed, the wounds, with one exception, were found to be healed. In disease of the joint, where splint-rest is required, whether in the early stages or after operation, plaster of Paris affords the necessary support, while it permits the patient to get about with ease. In the early stages of fungous synovitis of the knee it had been found especially valuable after the limb had been straightened under an anæsthetic, the icebag-like action during drying preventing fresh inflammatory effusion. Mr. Jefferson quoted cases illustrating its utility in this disease. In illustration of the value of Sayre's jackets, Mr. Jefferson mentioned the case of a boy who had just had one of these jackets applied for the fifth time within eighteen months. Eighteen months ago he had acute pain and tenderness in the lower dorsal region, with slight displacement backwards of two vertebræ. Two large psoas abscesses, one on each side, were opened; these have now quite healed, and there is not the least pain or tenderness in the affected region of the spine—in fact, he may be said to be well.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Brighton 12, Leicester, Bristol 16, Portsmouth, Huddersfield 17, Birkenhead, Derby, Nottingham 18, Cardiff 19, Bolton, London 20, Bradford, Edinburgh, Preston 21, Newcastle-on-Tyne, Oldham, Birmingham 22, Norwich 23, Leeds, 24, Wolverhampton, 25, Salford, Halifax 26, Sheffield 27, Manchester 28, Blackburn, Glasgow, Plymouth 29, Hull, Sunderland 30, Liverpool 31, Dublin 34.

FROM diseases of the zymotic class in the large towns last week the highest annual death-rates per 1,000 were— from whooping-cough, 2.9 in Cardiff and 3.6 in Hull; from scarlet fever, 1.2 in Liverpool, 1.4 in Blackburn, and 1.5 in Leeds; from measles, 0.9 in Liverpool; and from "fever," 1.1 in Liverpool and in Preston, and 2.4 in Blackburn. The 47 deaths from diphtheria included 24 in London, 10 in Glasgow, 2 in Portsmouth, and 2 in Birmingham. Small-pox caused 8 deaths in London, 1 in Nottingham, 1 in Sheffield, and 1 in Newcastle-upon-Tyne.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 43, Bombay 27, Madras 39, Paris 25, Geneva 21, Brussels 24, Amsterdam 28, Rotterdam 28, The Hague 25, Copenhagen 27, Stockholm 28, Christiania 18, St. Petersburg 41, Berlin 21, Hamburg 30, Dresden 22, Breslau 30, Munich 29, Vienna 29, Prague 30, Buda-Pesth 27, Trieste 36, Venice 37, New York 26, Brooklyn 22, Philadelphia 23, Baltimore 30. No returns were received from Rome, Naples, or Turin.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 7, 1883.

ULTRA-PECULIARITY.

We have, on other occasions, had forced upon us the unpleasant necessity of animadverting somewhat strongly on the proceedings of a certain class of human fatalists who rejoice in the well-deserved cognomen of Peculiar People. But a few months ago, one of these self-indulgent interpreters of scriptural promises found himself summoned to answer a charge of having, by neglecting to invoke medical assistance on his dying child's behalf, thereby contributed to its death. In this case, as in one of a similar nature within the past few days, the graver accusation was not maintained; and in each instance the fathers have been liberated with the fiction of no worse punishment than a homiletic indication from a coroner of the estimate which judicial functionaries are disposed to form of eccentricities involving sacrifice of life.

In matters affecting individuals or numbers, and where by respecting the sentiments of a few these may be allowed to gratify their vanities or their fads without attendant injury to other, and often helpless, members of society, we have at all times advocated a policy of non-interference. The vagaries of the "Peculiar People," however, do not come within the category of harmless foibles; on the contrary, we have now more than one or two illustrations of the grievous damage they inflict on those least able to remove themselves from the fateful influence of ignorant superstition; and with the evidence of two actual deaths to prevent which every attempt that might have been made was burked

by the influence of peculiar views, it becomes our imperative duty to call aloud for the exercise of such power as shall prevent future repetitions of a dread farce like that recently enacted with the assistance of a War Office clerk, his wife, and a sister of the latter. These lights of peculiarity had apparently been members of the sect but eighteen months, and this has been their first appearance in connection with death unattended by measures for its prevention. The victim in this case was a delicate child, who had been ailing for some time, and though the parents are said to have been uniformly kind and careful themselves in dealing with their offspring, they yet, in obedience to their "religion," omitted all other endeavours to save the little life plainly on the wane. To those practical persons who are not able to view such proceedings in the light shed on them by "peculiarity," there is something of a very disagreeable nature about a creed that enables the most sacred claims upon our humanity to be thus unconcernedly discarded. To a great many people the revelation that nineteenth century English law not only permits but even encourages the inculcation of principles that would be considered enormities in a savage, will come with a shock of painful and incredulous surprise. And yet the fact is so: it is open to any father of a family to suddenly discover himself overborne by "peculiar" views, and under their influence to migrate with his young and possibly burdensome dependents to some fever-stricken neighbourhood, where it will be quite compatible with "peculiar" views for him to be the sorrowful witness of a succession of deaths among his offspring, the while he neither asks assistance from a doctor, nor does aught to ward off the deadly visitor, beyond placing his hands in "laying-on" position on the bodies of his dying children. Such a father has a right to expect that the verdict of manslaughter righteously returned against him by the coroner who sits to inquire into the cause of the unregistered deaths, will be set aside as being incapable of support; and "peculiarity" will grow in consequence in popularity and greatness with every additional proof of the law's adaptability to its eccentricities.

It may, of course, be urged that such a consequence as has been suggested above is impossible; that the existence of any circumstances pointing to suspicion of preconcerted intentions would swiftly bring upon the offender a well-deserved punishment. Hitherto, we admit, there has been nothing of a kind to suggest maleficent proceedings in the several cases in which "Peculiar People" have been unpleasantly interested; but what we wish to insist on is, that by as much as the knowledge is spread among the masses that "peculiarity" in respect to religion may be relied on to exonerate from blame where negligence is evident, then both the ranks of the "peculiar" will become inconveniently crowded, and the proportion of unregistered deaths will grow to such an extent as to necessitate a very decided attitude on the part of the Government towards its principal cause.

The remedy is, of course, not difficult to see; but it cannot be applied without such co-operation on the part of intelligent jurors as these seem at present disinclined

to proffer. The fact, however, that within a short time no less than two indictments have arisen from the existence in our midst of a false religion that savours most strongly of convenient superstition, ought to afford a warning of the possible mischief it is capable of; and measures should be formulated with a view, at least, to the preservation of innocent life in the future, even if no direct repressive steps can be sanctioned which might appear to deal too harshly with that much-abused mystery, "the liberty of the subject."

THE CASE STATED AGAINST THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES BY THE ATTENDING PHYSICIAN.—
No. VII.

We pointed out in our last article that the decision of the Select Committee of last session to confirm the notification clauses of certain local Acts was based upon an *ex parte* statement furnished by a number of Town Clerks and Medical Officers of Health at the instance of the English Local Government Board. Even as a statement of the case by these gentlemen, the evidence before the Committee was, as we pointed out, scarcely worthy of consideration, because it was nothing but a chorus of "satisfaction" on their part, and contained no facts or statistics to show whence that satisfaction arose. The question to be answered is not whether corporate officials are satisfied with the notification system, but whether or not the public is protected against infection by that system? The notificationists come to Parliament and ask for powers, admittedly without precedent, and confessedly an interference with individual liberty, and they claim these powers on the ground of experience of the benefits resulting from their exercise; but they altogether fail to show the gain derived from the system, though there are sufficient means of ascertaining with reasonable certainty whether such benefits have really accrued. To do this the Local Government Board might have advantageously asked the Medical Officers of Health the following questions:—

a. Can you show by a comparison of the *death register* of your town, before and since the introduction of the notification system, that the zymotic mortality has been materially reduced in the latter period independently of other causes?

b. Can you prove by statistics of the number of persons who died within your town *unattended by a qualified medical practitioner*, that the notification system has not caused concealment of disease or driven the population into the arms of quacks and prescribing chemists?

There should not be the least difficulty in giving definite replies to these queries, and without such replies no one can judge of the value of compulsory notification.

By the law of Death Registration—

a. Every registered medical practitioner in attendance on a deceased must give to the person who is to give the information for registering the death a certificate of the cause.

b. The person who gives the information must deliver the certificate to the Registrar, under penalty of 40s.

c. The Registrar must state cause of death when so certified in his record; but when the deceased has been

attended by no one, or by an unqualified practitioner, he must enter the death as "uncertified."

d. The Registrar must give gratuitously a certificate for burial.

e. Every such certificate must be handed to the person who buries, under penalty of 40s.

f. If no burial certificate is produced, the person who buries must at once inform the Registrar-General thereof.

g. No child's body shall be buried as still-born without special precautionary certificates.

It will be observed that under this law every information desired is available, and that it is, therefore, easy for a Medical Officer of Health to compare, day by day and year by year, the mortality from any class of disease, and to illustrate the actual results from notification by proving that zymotic deaths have been reduced in number by its agency.

One only out of the twenty-two Medical Officers of Health (Huddersfield) has made any attempt to produce this evidence; they have given abundant proof of a reduction in the number of cases of infectious disease reported under the notification system, and they have most illogically argued that because reports have become fewer since the compulsory notification system was adopted, disease must also be less prevalent. We say that a falling off in the number of reported cases proves the exact reverse; that it shows that the public and the medical profession who, at first, sent in their notifications because they knew nothing of the consequences, and feared punishment if they omitted to do so, have since learned that punishment is improbable, and that notification is the father of all sorts of inconveniences, and consequently disease is kept secret. We believe that the sanitary authorities of the notification towns are living in a fool's paradise, mistaking decrease in notification reports for decrease in disease, and that they either designedly or neglectfully ignore the sources of information afforded by the death returns.

It is easy to evade notification—impossible to cheat death—and therefore, in our opinion, a comparison of *death-rates* before and after the introduction of the notification system would have been far more reliable as a test of improved health than any comparison of semi-voluntary notification reports. Moreover, an examination of the death certificates would afford valuable information of another sort; it would show to what extent persons dying from infectious disease had been attended by quacks or prescribing chemists, or left without attendance, and if it appeared upon investigation that the percentage of persons who died without the ministrations of a qualified practitioner had materially increased as a sequence of the introduction of the notification system, we should then be entitled to assert that the public was being driven to resort to unqualified practitioners—who are not amenable to notification law—in order to conceal the existence of the infection, and *ergo*, that the disease was being secretly disseminated in spite of the notification law.

This form of evidence is, unfortunately, not at our disposal. We have addressed to the English Registration Department a request for information whether any series of documents exists which would enable us to form a judgment on these matters, and we have been answered that no local mortality statistics are to be had except in the reports of the local authorities. The Medical Officers of Health, however, have this evidence in their hands,

and, notwithstanding repeated challenges to them to prove their case in this way, they have refused or omitted to do so, but have paraded quantities of figures to show that compulsory notification has reduced the number of cases of reported disease, being apparently unconscious that thereby they have to a certain extent proved the case against themselves.

The Report laid by the Local Government Board before the Select Committee gives us, however, some information. In the first place, it proves to us beyond doubt that, in many towns in which all sorts of benefits are alleged to have resulted from compulsory notification, the system has really no existence, and yet the supposed gain to the public health is as palpable as in those towns in which the system is rigidly enforced.

The following table sets forth the number of notifications for each 100 of the population of various towns in the year 1881-2:—

Rotherham ...	3.40	Oldham ...	0.59
Preston ...	1.57	Derby ...	0.57
Leicester ...	1.50	Norwich ...	0.53
Jarrow ...	1.25	Reading ...	0.52
Warrington ...	1.08	Blackburn ...	0.40
Manchester ...	1.05	Burton ...	0.42
Barrow ...	1.01	Bradford ...	0.38
Stalybridge ...	0.92	Lancaster ...	0.34
Llandudno ...	0.63	Huddersfield ...	0.22
Bolton ...	0.63	Stafford ...	0.075

Comparing by this table the number of cases reported in individual towns with the population of those towns, we find that in Rotherham the proportion was 3.4 cases per cent. of the population; in Preston and Leicester, 1.5 per cent.; while in Stafford, the percentage was only 0.075; and in Huddersfield, only 0.22. In other words, notification was forty-five times less active in Stafford than in Rotherham, yet we find it officially stated that the local authorities were just as well "satisfied" in the former as in the latter town, except that the Rotherham Town Council object strongly to pay the doctors for the reports which they force them to make. Again, in Manchester and Huddersfield, the local authorities are, as they say, thoroughly "satisfied" with the working of the system, although, in these towns, the Acts do not produce one report for every half dozen which are sent in in other towns. It must, in fact, be taken as proved by this table, that, though the diversities of system and the variations in the extent to which notification is in activity in different towns, make the system an absurdity, nevertheless, all the Medical Officers of Health are equally "satisfied" with their own method of using the law, and the public health of all the towns seems to be equally benefited. This conclusion is quite enough to discredit the whole of the reports upon which the Select Committee formed its judgment.

(To be continued.)

In the *Gaz. Hebdom.*, M. Vigier states that camphor may be perfectly suspended, and become easily divisible, by the following formula:—Camphor 15 grains, gum arabic 30 grains, one yolk of an egg, and 2 ounces of decoction of linseed.

DR. RICHARDSON ON MEDICAL MEN.

In an admirable address delivered before the Medical Union Society, at the annual *conversazione* of that body, on Wednesday last, Dr. Richardson urged the necessity that exists for medical men to become each day more and more entirely masters of the details relating to their profession, because of the increasing interest exhibited in questions and sciences allied to medicine by the ever-growing band of workers who are making themselves masters of these sciences. On this account, too, he insisted that it is much more difficult now than it formerly was for a man to signalise his claim to distinction, for where once there were none to dispute it with him, there are now a succession of discoverers, no one of whom can hope or expect to occupy for more than a most limited time the attention of his contemporaries before he is eclipsed by a yet more brilliant claimant for notice. In addition, also, to the competition thus introduced Dr. Richardson instances as hindering the progressive influence of medicine the exceedingly small representation it enjoys in the ruling bodies of the nation. Thus, he declares that medical interests are altogether unrepresented in the Upper, and barely represented in the Lower House. In the Commons' House the aristocratic interests have 272 representatives; the fighting interests, 168; the landed interests, 267; the law interests, 122; the liquor interests, 18; the moneyed interests, 25; the literary and scientific interests, 80; the official interests, 113; the railway interests, 113; the trading, commercial, and manufacturing interests, 155; the medical interests, 4; the labouring interests, 2.

The subject of professional etiquette caused Dr. Richardson to give expression to most decided opinions antagonistic to the custom now so prevalent, by which different medical men accept the treatment of cases which they know to be in the hands of other practitioners at the time. It is easy to understand how strongly the danger arising from neglect of due professional relationships would strike an observer of Dr. Richardson's perception, and most of us who reflect at all on the consequences that will arise from a continuance of existing irregularities will agree with him that they are very bad for the "dignity and sterling interests of the profession of medicine, and that if they must go on without any change, they must lead rapidly to loss of respect and confidence in medical opinion and practice." Nor can we for a moment think that this picture is overdrawn, for Dr. Richardson has illustrated the evils of the present system too plainly for us to entertain so pleasant a delusion. He says: "I remember the time perfectly when if a patient had consulted a physician or a surgeon it was accepted as a definite rule that if another one were to be consulted the first should be informed of the fact, and the two should hold a conference personally or by letter. In these days that rule, as a fixed rule, is broken continually; broken, as it seems to me, by a kind of tacit consent which the public may take advantage of to any extent. I have had, for instance, a patient, my patient, if I may strictly use the words in their old meaning, who has been at the same time under the care, if I may call it the care

in the old meaning of that term, of three other physicians, not one of whom has had a word of communication either with each other or with me on the case, and not one of whom has seemed to be either surprised or offended. There are scores of wealthy sick people who are being treated under precisely similar circumstances and not a few who in the self-same day make their visits on different practitioners, and afterwards, in conversation with friends and acquaintances, discuss every word that has been told, and comment on the differences of statement, manner, and opinion, as if they had been to the Royal Academy and were giving their opinions of the differences of style and manner and skill of the different exhibitors."

The cure for this undesirable state of things is given in the adoption of such unity of act and thought and word as shall ensure that all the future profession shall possess a common standard of intelligence, and of the science and art of medicine. We could devoutly wish this may be so, but coming generations of schoolboy medical students must be vastly different from those that are met with now if the commonality of them are to reach the intellectual status of the picked men of present day entries. When a University degree in Arts is held to be the only sufficient test of preliminary education, a degree conferred after at least two years' actual residence and training within University precincts, then we may begin to look for unanimity of thought and action and word; but the idea is wholly incongruous with the mixture of men and boys highly educated, half-educated, and not educated at all, who now constitute an average year's entries into the medical profession.

Dr. Richardson, though perhaps a little carried away by the occasion on several points, nevertheless afforded the Medical Union Society an admirable outline of the course of action they should pursue. His speech will, we trust, be productive of successful results in amount to justify the importance lent to the Association by his approval of its aims and objects.

THE ARMY MEDICAL SERVICE.

LITTLE by little the tendency of opinion of the committee now sitting at the War Office seems to be oozing out. A short time ago a statement appeared in the daily journals to the effect that that committee was extending its inquiry to the nature of medical arrangements adopted in other campaigns than that so recently ended; and still more lately the statement occurs that the old regimental system, as regards the medical officers, is certain to be re-established, at least to some extent. *Apropos* to these points an important statement occurs in a *brochure* relating to the war now ended: it is that "once your men go to the field hospital, and you seldom see them again; in this way many of our regiments melted away after we reached Cairo." So it was in Abyssinia; so in the Mutiny campaign; in the Crimea; and still earlier in the present century, during the Peninsular war. It was for this very reason that Sir James McGrigor broke up the system of general hospitals as they then existed,

instituting in their stead regimental hospitals, from which the regimental surgeons, energetically seconding him, succeeded in returning so many convalescents to the ranks of their regiments that it has been stated that "the extraordinary exertions of the medical officers of the army might be said to have decided the day at Vittoria, for their exertions had undoubtedly added a full division in strength to Lord Wellington's army, and without these 4,000 or 5,000 men it is more than doubtful if his lordship, with all his unrivalled talents, could have carried the day. Perhaps, without that material addition to his force, he would not have risked an action." The circumstance here related is matter of history, and of itself surely sufficient argument in favour of regimental hospitals in war service. On the occasion alluded to, field hospitals were also employed, but only for the first treatment of wounded, the men injured being subsequently distributed as far as possible to the regiments to which they severally belonged. For the ordinary medical duties of garrisons in times of peace, the experience of "unification" already acquired has demonstrated that it is less adapted than was that combined staff and regimental system which it has superseded. In consequence of the frequent changes of medical officers at a given place which the present system demands, officers are driven to consult, and, as a matter of course, pay private practitioners rather than inform a succession of strange medical officers the nature of the illness from which they, or other members of their family, happen to suffer. Soldiers, and, when married, their families, are, when ill, under the necessity of submitting to the very things against which their officers go to expense and otherwise put themselves to much inconvenience to avoid. The soldier, his wife, and children have not only in many instances to tell their ailments to different strangers in quick succession, but to take as many different kinds of physic from the prescribers, each of whom has his own special theory as to the nature of the "case," and of the particular method of treatment to be followed. Let the several members of the War Office committee place themselves under circumstances such as are thus indicated, and at the end of the ordeal let them say what they think of it.

Notes on Current Topics.

The Medical Union Society.

THE Medical Union Society, the formation of which we noticed in November, held its first annual *conversations* on Wednesday last at the Holborn Town Hall, Gray's Inn Road. The interest of the occasion was increased by the fact that an address was delivered to the members of the Society by Dr. B. W. Richardson, F.R.S., who indicated the mode in which the work of the Society could best be carried out. The chair was taken by Mr. Henry Power, F.R.C.S.; and a vote of thanks subsequently passed to Dr. Richardson was moved by Mr. Gresswell, student of Westminster, and Mr. Reade, student of St. Bartholomew's, respectively. Mr. Hulke, of University College Hospital briefly indicated the aims of the Society, and welcomed the visitors present to the meeting prior to the delivery of

Dr. Richardson's address. This last was followed by a vocal and instrumental concert of unusual excellence, to which the following ladies and gentlemen contributed: Madlle. Noemi Etty and Misses M. Lennon, Maynard, and Marie Hayward, Signor Salviani, Mr. Viotti Collins (violinist), Mr. H. Gordon, and Dr. Armand Semple. Signor d'Havet Zuccardi and Mr. W. R. Cave directed the vocal and instrumental parts respectively, the latter being contributed by the West London Orchestral Society. It says a good deal for the influence the new society possesses, and for the interest it excites, that such an admirable performance as that provided for its guests could be secured with the aid of purely voluntary services; in the direction of scientific objects there was exhibited, under the management of Messrs. Alfred Stokes and George Stevenson a noteworthy array of microscopical specimens and of surgical and other instruments, Messrs. Arnold and Sons, Baker, and Watson contributing to this part of the display. The attendance of guests was very numerous, from six to seven hundred ladies and gentlemen having accepted the Society's invitation. Among the more eminent members of the profession present were—Dr. Sieveking, Dr. Southey, Dr. Danford Thomas, Dr. Meadows, Dr. Forbes Winslow, Dr. Spencer Cobbold, Dr. Broadbent, Dr. J. Milner Fothergill, Mr. A. E. Durham, Mr. Henry Power, &c. Much interest was excited about half-past ten by the introduction to the meeting of Chang, the Chinese giant, and his wee companion General Tiny Mite. The pair made the tour of the room, conversing with many ladies before finally retiring.

Teetotalism in the Army.

MEDICAL officers in regiments know very well that, however excellent a thing in the abstract total abstinence may be for soldiers, there are occasions on which "a tot" of spirits is not only far more relished by them than would be either tea, coffee, or chocolate, but that it also has a more distinctly physiological action than either of the latter in giving an impulse to the powers of the body under fatigue, and exhaustion under certain circumstances. Of this examples are of nearly every-day occurrence in campaigns. In Abyssinia it was found that, after a time, the soldiers were unable to digest the coarse and imperfectly-cooked rations issued to them; that, as a natural result, physical strength was rapidly giving way; but that as soon as an allowance of spirits was given to them, all this became changed; their digestive powers were restored; and men who were about to become non-effective in the ranks, enabled to continue in their places—in other words, military efficiency of the soldiers was maintained on that occasion by rum. It is on record, also, that during the Ashantee campaign a taste of Navy rum helped a favoured regiment on an occasion when, but for the ration, many of the men would have broken down completely. It is the abuse of spirits and other strong drinks in the army that is to be condemned. Against this medical officers have ever been loud in their protests; but in regard to the proper use of these, as well as the times and circumstances when and in which they are advisable, medical officers are the proper judges.

Sir James McGrigor, writing of the Expedition to Egypt

in 1801, remarks upon the great extent to which on that occasion drunkenness prevailed among the British soldiers. He observed, however, that experience then gained had demonstrated how very little spirits are required in a hot climate to enable the soldier to bear fatigue, and how necessary regular diet is ("Medical Sketches," p. 86). Among the medical instructions issued for the preservation of health of the troops in Walcheren in 1809 was this:—That "on the evenings of the nights on which they mounted guard an extra allowance of spirits to each man would be essentially beneficial;" also, that in the sickly season "a small portion of unmixed spirits might be usefully allowed early every morning." We read also that during the American War of the Secession one noted division of the army consisted of temperance men. No spirits were issued to them. Morning and evening a tonic was given to them, this tonic chiefly composed of whisky flavoured with wild cherries!

The Vacant Chair of Physiology at University College.

THE Jodrell Professorship of Physiology at University College, vacated by Dr. J. Burdon Sanderson on his appointment to the Waynflete Professorship at Oxford, has been conferred on Mr. Albert Schäfer, F.R.S. Mr. Schäfer has for a long time assisted the Jodrell Professor to carry out the work of instructing his classes; and his reputation as a physiologist and histologist is so well established both in this country and abroad that general satisfaction will be felt with the decision of the electors in this case. It is, moreover, a graceful and appropriate recognition of the valuable services already rendered to English science and English students by Mr. Schäfer's assiduous efforts to advance the one and instruct the other.

Health Lectures at Cheltenham.

ON January 27th, Dr. B. W. Richardson, F.R.S., delivered a lecture on "Health in a Health Resort" at the Assembly Rooms, Cheltenham. This was the first of a series of three lectures to be given in the same place, the second being fixed for February 15th, when Professor de Chaumont, M.D., will discourse on "The Health of Armies in Peace and War." The concluding lecture of the series will be delivered on March 14, by Dr. Thorne Thorne, who has selected as his subject "Channels for conveying Infection to Households: how they may be recognised and dealt with."

Dublin Hospital Sunday Fund, 1882.

THE Honorary Secretaries have published a full list of the subscriptions, collections, and donations to this Fund for 1882. The total amount collected was £4,174 6s. 10d., of which about £4,000 will be available for distribution amongst the participating institutions. Considering the state of Ireland, and the relative scarcity of money resulting therefrom, this is a very satisfactory outcome of the collection, and reflects the greatest credit on the Honorary Secretaries, Lord Brabazon, Dr. Grimshaw, and Messrs. Robert O'Brien Furlong and Thomas Pim.

Homœopathy.

A FEW weeks since we called the attention of our readers to some vile compounds which are described in the Homœopathic Pharmacopœia—the gonorrhine, leucorrhine, and other nasty filth put into the mouths of dupes by crack-brained practitioners of medicine. The *Philadelphia Medical Times* now states that the remaining portion of this Homœopathic Pharmacopœia was in great part stolen *verbatim* from the United States Dispensatories, and that after a very brief law suit the whole edition has been suppressed under the copyright laws. But was there ever a more telling proof of the assumptions of modern homœopathy than the fact that for the guidance of its votaries the leading business firm devoted to such speciality should provide stolen extracts from recognised standard scientific therapeutic treatises?

The Irish Intermediate Examinations as Preliminary to Professional Study.

APROPOS of the results of the preliminary examination of the Irish College of Surgeons, we remind our readers that it is now open to all intending students to pass their preliminary examinations without coming to Dublin, even before leaving school. The Council of the College has recognised, as equivalent to their own examination, the pass of the Irish Intermediate Education Board in all those subjects which are required by the General Medical Council. These subjects are as follows:—

1. English language, including grammar and composition. 2. Arithmetic. 3. Algebra. 4. Geometry. 5. Latin translation and grammar. 6. And any one of the following optional subjects—*a.* Greek, *b.* French, *c.* German, *d.* Natural Philosophy.

All these subjects can be passed in *any grade* before the intermediate examiners at the local centres of examination throughout Ireland or in Dublin, and masters can send their pupils to such examinations direct from the school. It is to be recollected that it is necessary to produce to the College a pass in *all these subjects*, as the College will not allow students to supplementalise in a deficient subject.

Indian Corn.

Is the use of Indian corn as food really pernicious to health? A "fashionable" journal contains the somewhat alarming statement that those who eat Indian corn go mad; that this result is well known in Northern Italy; and that in Venice one-third of the persons in the lunatic asylum are there owing to having been nourished with this food. To say the least of it, the statement so made requires confirmation; and yet it is of sufficient importance to indicate the propriety of its being investigated. Our readers scarcely need to be informed that the cultivation of maize is more extended than that of wheat, rye, or sorghum; that in a part of France, almost the whole of southern Europe, a great part of the East, and Africa, and almost the whole of North America, this grain furnishes the chief food of the people; moreover, that in Great Britain and Ireland it is extensively used in various forms, of which *Oswego* meal is one. Hitherto it has had the reputation of being wholesome and nutritious as food, and hence the propriety of the grounds being inquired

into on which the reputation of Indian corn is now assailed.

Royal College of Surgeons of England.—Lecture Arrangements, 1883.

PROFESSOR PARKER, F.R.S., commenced his course of nine lectures, "On the Metamorphosis of Suctorial Fishes and Batrachia," on Friday last. Professor Flower, F.R.S., F.R.C.S., will afterwards give nine lectures, "On the Anatomy of the Horse and its Allies," commencing on Monday, February 26th. The lectures will be resumed in June by Mr. Frederick S. Eve, F.R.C.S. (Erasmus Wilson Lecturer), who will deliver three lectures, "On Cysts and Cystic Tumours in General." Professor Jonathan Hutchinson, F.R.S., F.R.C.S., will then give six lectures, "On Certain Diseases of the Tongue." The entire course for the year will be completed by Mr. Henry Power, F.R.C.S., who will deliver three lectures, "On the Lachrymal Apparatus and Accessory Organs of the Eye."

Investigations into the Origin of Whooping Cough.

SOME degree of interest attaches to the recent investigations of Dr. C. Burger, of Bonn, who in the *Berliner Klinische Wochenschrift*, of January, 1883, describes at length the special micro organisms of pertussis, which he states can be found in any specimen of whooping-cough sputum. Dr. Burger says: "the course and symptoms of the whole disease are best explained by the development of this fungus."

In the recent Fothergillian prize essay, on "whooping-cough" by T. M. Dolan, F.R.C.S., the fungoid nature of the disease is clearly and boldly insisted on; very convincing proofs are brought forward to support the views of the writer. In fact, short of actual demonstration, Mr. Dolan may be said to have established the fungoid nature of pertussis.

Verification of his theory has come from the work of Dr. Burger. Considerable interest has been excited in England over the bacillus tuberculosis. We trust attention will now be directed to the bacillus of pertussis, and that some of our investigators such as Drs. Heron, Charnley Smith, &c., may verify the observations of Dr. Burger. According to Dr. Burger micro-organisms appear under an immersion lens vii, ocular D of Seibert Krapf, as small elongated elliptical bodies of unequal length, the smallest being double as long as broad. Under a very strong power transverse subdivision can be detected in the longest of the specimens. They may form chains or groups, but are generally isolated and scattered singly all over the fluid. They bear a certain resemblance to leptothrix buccalis, the spores of which are often found in whooping-cough symptoms, but the latter are larger and stouter, and near them the filiform matured leptothrix is always present.

Occasionally some of the specific bacilli are found to be inside the mucus cells in the sputum. The bacillus is easily prepared; they can be readily recognised if coloured in the usual way by watery solutions of aniline. Fuschin and methyl-violet were employed by Dr. Burger.

As in the case of bacillus tuberculosis, this micro-

organism is best studied when mounted in the dry way. Dr. Burger concludes that this bacillus is the actual produce of pertussis, because it is not found in any other kind of sputum, because it is so abundantly produced in whooping-cough that its influence cannot be doubted, because its abundance increases in direct proportion with the severity of the disease. The discovery of the bacillus tuberculosis marks an important era in the study of the pathology of phthisis, and similarly it may be said that the substantiation of the views in the Fothergillian essay also revolutionise and mark a new epoch in the pathology of pertussis.

The Adulteration of Food Act.

THE Act to prevent food adulteration must be very laxly administered, otherwise it would not happen that falsified articles of food and drink are sold wholesale in the London markets. It appears that last week a very large quantity of adulterated pepper was sold by auction in Mincing Lane, and in spite of the indignant remonstrance of a section of the trade. A sample of this pepper was, on analysis, found to consist of an inferior kind of pepper mixed with 44 per cent. of sand and dirt; nevertheless, it realised a good price, the buyer intimating that it would be used for feeding poultry. We are curious to know whether this mixture of pepper, sand, and dirt paid the same duty as the genuine article? If it did, then all we can say is that the officers of Excise must either be very remiss or careless, or they must wink at the fraud about to be practised upon retail dealers and the public. Only a few weeks ago we had occasion to complain of the enormous adulteration of coffee with chicory. The falsification of an article of every-day home consumption as that of coffee was carried on with the knowledge of the Government officials because it paid duty and was said to be innocuous, or in no way injurious to health. Turning to drinks, brandy and wine are no better off. Scarcely a genuine sample of Cognac brandy is to be had. In most instances the spirit sold under the name of brandy is nothing more than a raw kind of beet, or potato spirit, with a flavouring of the genuine article, or more frequently with some flavouring material which imparts a bouquet and effectually disguises the unwholesome compound. The trade is no doubt a profitable one, but it is a very improper one, for in place of a cordial we get a spirit in many ways prejudicial to health.

The Mullein Plant.

A CONTEMPORARY contains an account of a therapeutical research into the alleged virtues of this plant in the treatment of pulmonary consumption. The *Verbascum thapsus*, or great mullein, is a weed found in this country, in Ireland, and in the south of Scotland. In Ireland, however, it has always been cultivated on a rather large scale, in answer to a steady demand for it by phthisical sufferers; and our daily contemporaries contain frequent advertisements offering it for sale. It is difficult to imagine that this could have gone on so long unless there was some practical benefit obtained; and we therefore notice the matter in the hope that some of our readers may be induced to look into it. The inquiry was conducted in St. Vincent's Hospital, Dublin, by noting the weekly

weights of consumptive patients in various stages, who were treated on mullein solely, and to the exclusion of cod-liver oil, koumiss, or any other weight increaser. The mullein was given in the old Irish way, by boiling an ounce of the leaves for ten minutes in a pint of milk, straining, and administering it warm with or without a little sugar. This does was given twice daily, and was found grateful, and after a little time palatable—much more so than either the watery infusion or the juice of the leaves. The inquiry is still progressing; but Dr. Quinlan finds that in pre-tubercular and in early stages a decided increase in weight is obtained; and the cases certainly appear to establish this. In the advanced stages the disease progressed and the weight diminished, in spite of the mullein, which, however, appeared to afford great relief to the cough and dyspnoea. Phthisical diarrhoea, moreover, when present, was completely checked by it. In phthisical perspirations it was found utterly useless, and these had to be controlled by the hypodermic use of atropia sulphate. The patients were all much gratified at the mullein treatment, in which they had great faith, and this might have induced them to imagine a greater amount of relief in the advanced stages than they really obtained. Still, the increases of weight in the early stages look promising, and, upon the whole, we think the subject is worth inquiry. We see by the recent Lettsomian Lecture of Dr. A. E. Sansom that extract of the *Convallaria majalis* (the well-known lily of the valley) has properties in the treatment of cardiac disease and dropsy equal, and in some respects superior, to digitalis. This was introduced by Prof. Sée, who found it employed by the Russian peasantry. It is a pity that these popular remedial simples are not more looked into.

Dr. Littlejohn and the Dublin Physicians.

THE following resolution in reference to Dr. Littlejohn's recent letter to the *Glasgow Herald* has been unanimously adopted by the Council of the Irish Medical Association, and sent to us for publication:—

Resolved:—"That this Council repudiates the unfounded imputation upon Dublin physicians contained in a statement publicly made by Dr. Littlejohn, Medical Officer of Health for the City of Edinburgh, in a recent letter to the *Glasgow Herald*, to the effect that 'the profession (in Dublin) protests loudly against a loss of fees where any of their patients, however badly housed, are removed to hospital so as no longer to be a source of danger to the community.' That this Council expresses its surprise and regret that Dr. Littlejohn should have publicly attributed such motive to the members of his own profession in Dublin without attempting in any way to substantiate the accusation. That a copy of this resolution be forwarded to Dr. Littlejohn and the weekly medical journals."

No Chinese Need Apply.

THE American Treasury Department has decided that a Chinese wet-nurse must be considered as a labourer, and as such is excluded from admission to the United States, under the provision of the Act restricting Chinese immigration. This is a perfectly consistent decision. If there are good reasons to restrict the immigration of male Chinese labour, so are there to place the same embargo on the female. Wet-nursing is practically a labour, since the woman is pecuniarily rewarded for her work.

The Irish County Infirmaries.

WE observe with much satisfaction that the surgeons attached to county infirmaries in Ireland have reorganised their Association, which did such good service in former years in protecting these valuable institutions. A meeting of the Association was held on the 30th ult., at the Irish College of Surgeons, at which Dr. Brunker occupied the chair, and there were present—Drs. D. Jacob, Knott, Johnston, Minchin, Mackesy, Falkiner, Ridley, Bradshaw, Russell, Carte, Middleton, Mayne, Cullinan, Young, and MacDonnell. Letters of regret at not being able to attend were received from Drs. Kinkead, St. George, Palmer, Cabalan, Jordan, Hamilton, Moore, Bellew Kelly, Barton, Rawson, Chaplin, Lawlor, and Sir W. Millar. A discussion took place in which reference was made to the throwing out at Road Sessions of the Presentment for the County Kildare Infirmary. The present insecurity of many county infirmaries was also considered, and the desirability of attempting to remedy defects in the present system, and initiating improvements so as to anticipate hostile action in the future, was also fully discussed. It was resolved—

“That this meeting desires the Committee of the infirmary surgeons to take steps to protect the interests of the infirmaries in the proposed County Government Bill. That the Committee seek the advice and assistance of friendly M.P.’s and others with a view to the introduction of such clauses as shall enlarge and secure the benefits of the county infirmaries.”

We claim with confidence the warm support of the profession for this movement, especially as we are aware that the circumstances which have brought it together are most urgent. Increasing difficulty has been experienced from year to year in obtaining the necessary grants for the maintenance of these institutions because of the gradual lowering of tone of the bodies with whom the voting of the grant lies. This difficulty has been recently illustrated in the case of the Kildare Infirmary, which, during the absence of the surgeon from the Road Sessions in consequence of illness, was deprived of its grant by the influence of a local agitator. Moreover, Ireland is threatened with a County Government Bill in the coming session of Parliament, which, if passed, will commit the fiscal powers of the existing grand juries to elective boards of no higher standard than the present boards of guardians. Should this be so, the county infirmaries of Ireland which, since the year 1766, have been the centres of provincial surgery throughout Ireland, will be dependent for maintenance upon a class who will have little hesitation in shutting them up, if by so doing they can save a few hundreds a year or serve a politico-religious purpose.

We, therefore, highly commend the activity displayed by the infirmary surgeons, and we anticipate that, if the organisation is properly worked, it will receive, as it deserves, the hearty support of the Colleges and professional associations in Ireland.

THE *Sanitary Record* mentions the prosecution of a New York grocer for selling as pure cream of tartar a mixture consisting of 92 per cent. of ground gypsum and 8 per cent. of tartaric acid.

House Builders' Eccentricities.

AT the present time, when in every quarter of “greater London” dwelling houses innumerable are being erected to meet the presumed demand for this class of property, a good deal of instructive information respecting the peculiar estimate of sanitation entertained by builders can be gathered by any one curious enough to examine the houses recently built, or in course of erection. We have latterly given a good deal of time to the inspection of such premises, and with results confirmatory of the opinion so often expressed that a much more rigid supervision of these works is demanded than is generally given. One of the most striking instances in point is afforded by the construction of a great number of the new houses in course of completion at Bedford Park, Chiswick. The elevation of these dwellings is both neat and attractive, and, as a rule, the rooms they contain are sufficiently spacious for ordinary comfort; but the arrangement of the domestic offices is frequently carried out with almost perfect neglect of all sanitary precautions. We particularly refer to the fact that the “larder,” in which the food of the unfortunate families destined to live in the houses is placed, is almost invariably next to a water-closet, and in the majority of cases the doors opening into the two receptacles, for ingesta and ejecta respectively, are directly contiguous, while in even the best constructed only a partition wall divides the two compartments. Such a disposition cannot be at all a necessary arrangement, as the merest inspection suffices to indicate; and in a district which appears to be growing very rapidly in public favour, and to be each year more thickly populated, immediate steps ought to be taken under authority to prevent the repetition of blunders so glaringly detrimental to the preservation of health. We trust that by calling attention to the error we may be the means of remedying a conspicuous mistake.

The Proposed Abolition of Coroners in America.

THE Medico-Legal Society of New York having remitted to a committee to consider the reform of coroners' courts, has had before it its report, recommending: 1, the abolition of coroners' juries in most cases; 2, the substitution of salaried medical examiners, who are to act in lieu of coroners till there is reason to suppose that a crime has been committed, and report in duplicate to the coroner—who is to be a lawyer—and to the District State Attorney; 3, the reduction of the number of coroners, since the duties of these will in great part be transferred to the medical examiners; 4, power to be granted to the medical examiners to call in the aid of skilled chemists to make analyses.

Testimonials.

THE practical expression of gratitude is of too uncommon an occurrence between the public and our profession not to induce us to chronicle the fact when it assumes a tangible form. Occasionally we have the gratification of announcing that a certain practitioner has been presented with a silver salver by a few grateful patients, and that a house-surgeon, or the medical officer to a Friendly Society has received a framed parchment on leaving his post in token of appreciation of services

faithfully rendered. But it does not often take the practical and eminently serviceable form as was the case at Sidmouth (Devon) a few days ago, when Dr. Pullin of that town was presented with a magnificent microscope, a purse of one hundred guineas, and his wife with a silver urn and a silver casket by a few patients and friends "as a token of their esteem and confidence, and especially of their respect for the kind and conscientious manner in which he has discharged his duties to the poor during the last twenty-seven years." The gifts to Mrs. Pullin bore the following inscription:—"Presented to Mrs. Pullin as an expression of sincere regard from a few old and grateful patients of her husband." From the local papers we learn that Dr. Pullin has practised in Sidmouth for over thirty-two years, during which time he has never taken a week's holiday, that he has been health officer for many years, and has been foremost in every good and useful work in the town. Such a spontaneous expression of gratitude and appreciation of services rendered must be singularly gratifying to the recipients, and we have much pleasure in congratulating our *confrère* thereon.

The Medical Society of London.

ON Monday evening, 29th ult., Dr. Whipham, physician to St. George's Hospital, opened an interesting debate upon "The Association of Tubercle and Bacilli." The discussion was carried on with much energy, and in the end had to be adjourned to February 12th, at 8.30 p.m. On that occasion Dr. C. T. Williams will re-open the discussion, so that another full and instructive meeting is anticipated. The Society, which has undergone many vicissitudes since its foundation 110 years ago, is now apparently gaining strength and energy, and is probably at the present time in a better condition than that to which it has hitherto attained. The retiring President, Mr. Francis Mason, may be congratulated on the good and steady work which has been accomplished during his year of office.

On Monday last Dr. Sansom delivered the third Lettsomian Lecture; *subject*: "Mitral and Aortic Disease," which will appear in our next number.

Gresham Lectures.

FOUR lectures will be delivered in Gresham College by Dr. E. Symes Thompson on "Alpine Health Resorts." The lectures will be given on Monday, February 5; Tuesday, February 6; Thursday, February 8; and Friday, February 9—commencing each evening at six o'clock.

The Rectorship of the Edinburgh University.

THE *Medical Times and Gazette* says that among the names favoured by the Liberal students of Edinburgh University for the office of Lord Rector are those of Earls Granville, Rosebery, and Selborne; Viscount Sherbrooke, Mr. Trevelyan, and Mr. Campbell-Bannerman. A proposal, which emanates from a section of the Conservatives, that the Duke of Albany should be unanimously elected to the Rectorship, finds no favour in the Liberal ranks.

The Seat of Instinct.

THE curious theory has been put forward recently by Dr. W. A. Hammond, of New York, that the seat of instinct is in the medulla oblongata, his argument being based among other observations upon the capacity in acephalic monsters for suckling and similar instinctive acts, providing the medulla be present.

Personation.

IT is not an uncommon practice for quacks and other impostors to assume the names, and even the titles and degrees, of deceased eminent members of the profession for the purposes of imposing upon an indiscriminating public; but such tactics are not often resorted to during the lifetime of medical men. Such a case, however, occurred last week in the South of London (9 Winster Terrace, Peckham), where a man was discovered to have assumed the name of Dr. A. Hamilton Jacob, of Dublin, advertising himself as M.D. T.C.D., F.R.C.S., &c., and not content with that gentleman's speciality as an oculist, he added as extra attractions, and as evidence of his wide-spread accomplishments, "the cure of Consumption, Paralysis, Palsy, Gout, Asthma, Sciatica, Lumbago, and Neuralgia." But the Medical Alliance Association were unwilling to believe that a former ship's cook could embody so many healing virtues in his sacred person, and on Saturday last they summoned this gentleman before the Lambeth Police Court. Being, however, busily engaged in his philanthropic enterprise, he had no time to attend a common summons, and a warrant was accordingly issued for his immediate arrest. For the present, Dr. A. H. Jacob's prototype will probably cease from troubling and leave the pockets of a much-enduring public at rest.

Fæcal Gas as an Illuminant.

AN ingenious German has conceived and carried out a plan for the manufacture of gas from human fæces. "These are put in a retort, where they are not only dried, but decomposed by heat, the chief products being a light yielding gas, carbonic acid, tar, oil, and ammonia. As in ordinary gas works, the tar and oil are separated, the gases washed by being passed through water, the carbonic acid fixed, and the light yielding gas purified for use. There remain in the retorts the ash-constituents with a portion of carbon, which the inventor designates coke." The authority for this description, *Der Techniker*, informs its readers also that a Breslau Hotel has already been successfully lighted by means of this novel and presumably economical gas.

MR. SPENCER WELLS, the President of the Royal College of Surgeons of England, will deliver the annual Hunterian Oration in the theatre of the College on Wednesday next, at 3 o'clock. Members of the profession will be admitted on presentation of their private cards.

BRIGHTON now enjoys the enviable reputation of having the lowest death-rate of any of the large towns in the United Kingdom. According to the Registrar-General's returns last week, the death-rate was only 12 per 1,000 of the population, without a single case of a zymotic character.

The Irish Gaol Commission.

THE meeting of the Association of Surgeons of Infirmaries and Gaols in Ireland, which took place at the Irish College of Surgeons last week, had under consideration the relations between the Prisons Department at Dublin Castle and the medical officers, which have recently been so strained that the service in some districts has only with difficulty been carried on. It may be recollected that when the Prisons Act of 1878 was passed—which preserved to the fullest extent the rights of the prison surgeons then in office—a totally illegal attempt was made by the Irish Prisons Board to reduce salaries, remove the apothecaries without compensation, and force the medical officers to do the apothecaries' work gratuitously. A more audacious effort by a public department to over-ride the law and oppress a class of officers whom Parliament had carefully protected was never made, and owing to vigorous organisation and determined assertion of their rights by the medical officers, the Board was obliged to withdraw its scale of payment and reinstates the apothecaries, or else compensate them and pay extra for the performance of their work. Recently the same tyrannical spirit has shown itself in marked degree in the Castle administration of Prisons. All sorts of petty annoyances were put upon medical officers, and the determination was clearly shown to put "the doctors" under heel if it could possibly be done. The Board was, however, taught a lesson by one of its medical officers whom it tried to dismiss contrary to law, and it was obliged, after taking the advice of its legal advisers, to subside into a dignified silence, and withdraw all its arrogant manifestoes.

As the Irish Prison system is now administered it is plain that individual officers must oppose a concrete resistance to the aggressions of the Board, and the opportunity is now afforded for them to present their case to the Irish Prisons Commission, which has just held its first sitting, of which Dr. Robert MacDonnell and Dr. Sigerson are the medical members.

We observe, therefore, with satisfaction, that the Association, which met last week, appointed six gaol surgeons to represent them before the Commission, viz.—Drs. Carte, D. Jacob, Kinkead, Middleton, Falkiner, and Mac Donnell.

The points upon which opinions and information are requested by the Committee are as follows:—1. The supply of instruments and medicines. 2. Compulsory attendance on warders and their families, who reside outside the gaol. 3. Compulsory daily attendance on extra diet prisoners. 4. The necessity for trained hospital warders. 5. The increase of duties by order of the G. P. Board. 6. Suggestions for alterations in the dietary, sanitary, or hygienic improvements.

We hope that there will be no hangers back from this movement. We note the absence of a few names from the meeting, and trust that their abstention had a good excuse.

THE Municipal Council of Paris has voted the sum of £120,000, two-thirds of which are to be expended in the improvement of existing hospitals, and the remaining one-third to be expended in the erection of new establishments for the relief of the sick poor of that city.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

EDINBURGH.—ROYAL DISPENSARY MEETING.—The annual meeting of the contributors to this institution was held in the Council Chambers, Edinburgh, on the 27th ult., Lord Provost Harrison presiding. The annual report stated that the Dispensary still continued in an efficient state. There had been over 8,000 patients treated at the institution, while no fewer than 691 infants had had the beneficial operation of vaccination performed during the year. The subscriptions last year were slightly less than in 1881. The medical report stated that during the past year 8,382 patients had sought the benefits of the institution. Of that number 5,594 attended personally at the Dispensary, 1,808 were visited and treated at their own homes, 245 poor women were attended during their confinements, and 691 infants vaccinated.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 27th ult., the mortality in Edinburgh fell from 100 to 93, and the death-rate was 21 per 1,000. There were 17 deaths under 1 year, and 17 above 60, of which 4 were above 80, and one above 90 years. Diseases of the chest accounted for 50, and zymotic causes for 10 deaths.

EDINBURGH HEALTH LECTURES.—The subject of Dr. J. Halliday Croom's last lecture, under the auspices of the Edinburgh Health Society, was on "Nursing the Sick." The audience was a large one, and the discourse was made additionally attractive by practical demonstrations illustrative of the points sought to be impressed upon those present. Certain is it that if "preaching and practice" were synonymous, the sad results due to ignorant nursing would be unlikely to occur in the hands of those who heard Dr. Croom's sermon. But, unfortunately, nurses and the general public equally are afraid of air; and cleanliness and light, especially in poor homes, are not among the remedial measures generally adopted in "nursing the sick." Dr. Croom touched so ably, yet so simply, on so many topics about which the public should be well informed, that we hope to hear that his lecture has been printed for gratuitous distribution.

SCHOOL OF MEDICINE, SURGEONS' HALL, EDINBURGH.—At a meeting held on the 31st ult., the lecturers in the School of Medicine at Surgeons' Hall, Edinburgh, met for the purpose of appointing a lecturer in room of Dr. Keiller, resigned, when it was unanimously resolved that Dr. Angus Macdonald be appointed to fill the vacancy.

WEST KILBRIDE.—DEATH OF A CENTENARIAN.—Considerable doubt exists on the part of certain authorities as to whether the duration of life extends to 100 years, and yet from time to time instances of such longevity are recorded. A few days ago, at West Kilbride, the death took place of a woman at the advanced age of 104 years.

GLASGOW DEATH-RATE.—During the week ending with Saturday, the 27th ult., the death-rate of Glasgow was 30 per 1,000 per annum, the same as in the previous one, the death-rate of the corresponding weeks for 1882, 1881, and 1880 respectively being 22, 46, and 30.

EDINBURGH.—THE SICK CHILDREN'S HOSPITAL.—The annual meeting of the friends of and subscribers to the Hospital for Sick Children, Edinburgh, was held on the 29th ult., the Lord Provost presiding. From the annual report, which was read, it appeared that the children treated in the wards during the past year numbered 584, being 46 more than in the previous year, and that the number treated at

the dispensary was 6,270, an increase of 228. 192 of the cases in the wards were fever patients—the most expensive kind of case—whose cost was over £1,000 annually. The annual contributions were found insufficient to meet the expenditure, and in consequence the reserve fund was being gradually extinguished, and the directors earnestly appealed for enlarged contributions. Exclusive of legacies, the income amounted to £1,718, including—subscriptions, £1,242, and donations, £321. The expenditure was £2,519, showing an excess of £801 over the income.

GLASGOW ROYAL INFIRMARY.—The annual meeting of the qualified contributors and subscribers to the Glasgow Royal Infirmary was held on the 29th ult., in the Chamber of Commerce, Glasgow, the Hon. the Lord Provost presiding. In the course of his remarks his lordship drew attention to the fact that in the medical and surgical wards of the Infirmary last year, a much larger number of cases came under treatment than in any previous year—and that with a very low average rate of mortality—but, on the other hand, the necessary expenditure, although proportionally less than in previous years, had not been met by the annual ordinary revenue; and the managers had again been obliged to resort to the reserve fund to make up the deficiency, which he sincerely deplored. He also remarked upon the non-subscribing qualities displayed in the well-paid artisan, who received all the benefits of such charities as the Royal Infirmary, but contributed nothing to their support.

Literature.

CLINICAL LECTURES ON DISEASES PECULIAR TO WOMEN. (a)

A WORK so well known as that before us needs no lengthened review. We shall therefore content ourselves with pointing out some of the changes which we notice in the present edition. Firstly then, the type is larger, and this, together with the introduction of a large amount of new matter, accounts for the increase of the volume to 393 pages. The chief additions are to be found in connection with sub-involution, laceration of the cervix, fibrous tumours, and inversion of the uterus. The first of these subjects is treated at much greater length, and the symptoms, as well as the different modes of treatment adapted to different stages of the affection are entered into in more detail. Emmet's operation for the cure of lacerated cervix is mentioned, but in our author's opinion the evils resulting from this condition have been exaggerated, and the cases demanding operative interference are but few. Hysterotomy and the removal of both ovaries are added to the methods of treating cases of fibrous tumour of the uterus. The chapter on inversion of the uterus is, perhaps, the most interesting in the book. Dr. Atthill's observations upon the causation of this displacement, are, we believe, both new and original. Total extirpation of the uterus is permissible in some cases of cancer. In one such case, the fundus only was removed by the author, the disease being apparently limited to that region. In a similar case, however, he would perform Freund's operation. In the performance of ovariectomy, all antiseptic precautions are observed, excepting that the spray should not play directly on the abdomen. Chloroform administered by Junker's inhaler is preferable to ether. We observe also that the arrangement of some parts of the work has been changed, and also some new illustrations added, amongst which we notice Dr. Galabin's pessary for prolapse, the name is, however, said to be known as Galbanum's pessary. With this, and a few other exceptions, the book is free from even typographical errors.

Brief as our notice necessarily is, we have, we hope, said enough to show that the author has spared no pains to keep pace with the advance of this branch of medical science. We heartily congratulate him upon the success of this work, which has, in a little over ten years, not only reached a seventh edition, but has been republished in America, and also translated into French.

(a) "Clinical Lectures on Diseases Peculiar to Women." By Lombé Atthill, M.D. Dublin: Fannin & Co.

EASTBOURNE. (a)

MR. MOSELEY has collected a great deal of useful information regarding the advantages possessed by Eastbourne as a place of residence, and a winter resort for invalids. The town, he tells us, rests on a substratum of sandstone, the intermediate stratum of soil being light and porous; the beach is clear and absolutely devoid of mud or other impurity; the locality presents two varieties of climate—the one bracing and invigorating, the other mild—and what our author calls "emulsive." The mean winter temperature is $41\frac{1}{2}^{\circ}\text{F}$.; highest in July, about 75° ; the mean for that month, 60° ; annual number of rainy days, 168; annual rainfall, 31.6 inches. The neighbouring drives, and open spaces provide ample breathing space for visitors. The water-supply is abundant and good. From its position, Eastbourne enjoys a large amount of sun light. It is extolled by the author as a residence both in summer and in winter for invalids, and as indicating its advantages as such, he states that on an average of eleven years, 1871-81, the rate of mortality there was only 15.6 per thousand persons.

NOTES FROM SICK ROOMS. (b)

FROM this little brochure we can plainly see that Mrs. Stephens has been patient as well as nurse, and that she knows all the feelings and wishes of patients. For ourselves, we never really understood the views of the sick until we had undergone a long and painful illness; and therefore, we have read this little volume with sympathy and interest. The notes of nursing are careful and useful, and ought to be in the hands of all that band of educated ladies who have, to the great benefit of humanity, ousted Mrs. Gamp from her position of licensed torturer of the afflicted.

Mrs. Leslie Stephens gives excellent instructions *enent* the making of beef-tea, and to these we would add a supplement:—Should the chronic sufferer tire of beef-tea, add to each pint four oysters (if the month contain an R) and their liquor. This will entirely change the flavour, and render pleasant and appetising the drink which previously palled. Let the nurse make the beef-tea on her own fire, instead of sending the meat to the kitchen. She will find a wonderful improvement in the quality.

DIET FOR THE SICK. (c)

THIS is a very handy little cookery-book for the sick room, and contains a number of very useful and plainly expressed receipts. Reasonable economy seems to be studied throughout, and efficiency is always kept in view. In making this remark we would except No. 5^b, p. 41, for lentil soup. This is done with lentil flour, and is one of the worst receipts we ever saw. We give from personal experience a really good one:—Take of *German* lentils $1\frac{1}{2}\text{lb}$.; of raw meat bones (from the butcher, 20d. a stone) 7 lb.; of pot-herbs and salt, q.s.; of water, one gallon; put all these down to simmer on the hob, or on the cover of a close range, until the lentils have disappeared. This will take many hours, but will produce, with occasional additions of water, five pints of succulent, nutritious, and meat-tasting soup. It is filling and appetising, and we commend it to both the sick and to large families. The exact price of the five pints of soup thus produced is, excluding fuel, a fraction less than fifteen pence.

Royal College of Surgeons of England.—The following candidates, having passed the required examination for the diploma, were admitted Members of the College on Tuesday January 30th:—

Green, Henry, L.R.C.P. Ed., Norfolk Crescent, London.
Halliburton, W. Dobinson, Upper Norwood.
O'Kane, Michael, L.S.A., Camberwell.
Parsons, Charles William, L.S.A., South Hackney.
Treasure, W. B. Crawford, L.S.A., Crewkerne.
Trinder, Alfred Probus, Highgate.
Watson, Robert Walker, L.S.A., Highbury New Park.
White, Thomas Harry, L.S.A., Lincoln.

Correspondence.

THE CHEMICAL ANALYSIS OF DRINKING WATER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—The steps taken by the United States Board of Health, referred to in an editorial note of last week in the *Medical Press and Circular*, and which have for their object the determination of the relative value of the several methods employed in the analysis of drinking waters, are well deserving the notice of the Local Government Board of this country. The divided opinions of chemists at the present moment serve only to confuse, mislead, and unsettle the public mind. Some effort will surely be made by the new President of the Local Government Board to put an end to the scandal engendered by the monthly publication of two or three chemical analyses of the water supplied to London, which are not only directly contradictory, but are often apparently intended to discredit each other.

Although it is uncertain when the question of a pure water supply will form the subject of discussion in Parliament, it nevertheless continues to occupy the attention of all classes of intellectual and intelligent men both at home and abroad. As an evidence of this I would refer you to an interesting discussion, extending over two or three ordinary meetings of the Institution of Civil Engineers, concluded only a week ago. The paper which originated the discussion was one on "The Antwerp Water Supply." It appears that the inhabitants of this town had for years drawn their water supply from shallow wells, most of which were polluted by neighbouring cesspools, and it was therefore thought desirable to bring in a better and safer supply. It was proposed to draw the future supply from the river Nethe, but the great obstacle to carrying this into effect was that the water is so turbid and muddy that no ordinary method of sand filtration would render it clear enough, or remove the suspended organic and mineral matters. The inhabitants of Antwerp preferred their polluted well waters—which were clear and sparkling to the eye—to the dirty-looking, unpalatable, river water of the Nethe. Subsequent trials made with spongy iron as a filtering material proved to be more successful, and ultimately the water was, in appearance at least, so much improved that three eminent chemists to whom it was submitted certified to its efficient filtration, and also averred that "it possessed the power of destroying organic impurities and destroying the germs of putrefaction, of bacteria, and probably those of epidemic diseases."

This remarkable statement deserves somewhat closer scrutiny, and the natural inquiry is, what is spongy iron? Spongy iron is iron prepared by reducing hematite ore at as low a temperature as possible by means of carbon. The ore not being submitted to as high a temperature as is the case in the ordinary blast-furnace, the resulting metal is not homogeneous in structure, is vesicular and spongy, and can be easily broken up. Its action over water is said to be chemical—not mechanical. It exerts a reducing action, diminishing the quantity of organic carbon and nitrogen. It undoubtedly has a deoxidising effect upon water, and for this reason it has been found necessary, after passing water through spongy iron, to send it once more through a layer of sand. It is also said that the spongy iron employed in filtration in no way deteriorates—that is, so far as can be determined by the filter beds which have been in use for eighteen months. A remarkable property in itself, no doubt.

I have experimented with a house filter, and find some of the statements in no way borne out; with regard "to the complete destruction of bacteria and their germs," this is certainly not a fact. On submitting a number of samples of spongy-iron-filtered water to Dr. Koch's gelatine process and the microscope, I have had ample proof of the presence of myriads of living bacteria. It is not pleasant to chemists to have their results questioned and their analyses pronounced worthless, but as this is a matter which greatly concerns the public health, the truth should be told. It is but fair to say that, as my experiments proved to be unfavourable to spongy iron, the supporters and advocates of this material question my results. It is urged by them that the outer air was not carefully excluded, and, therefore, that the water became infected after it was

drawn from the filter, or that some infective germs had obtained access to my test tubes, and so forth. My answer to any objectors on these grounds is simply that it is a part of the filtering process as pursued at Antwerp, to expose the water, after it has passed through the spongy iron, *freely to the air* before it is delivered to their customers; and, furthermore, that samples of pure distilled water submitted at the same time, and under exactly the same conditions, to the gelatine process, show no sign whatever of any change. The gelatine test must, therefore, I think, be accepted as conclusive.

The results obtained by Koch's gelatine process are, to a great extent, palpable to the naked eye, and indisputably show the comparative vital activity of the organisms contained in each specimen of water examined; and in such a way that they can be photographed, and made a perfect record of the intensity of life in the liquid. The microscope subsequently employed removes every doubt, and enables us to designate the genus and species to which organisms may belong. In a little time I hope we shall have accumulated sufficient evidence of the fact that this mode of examining water is far more important to the profession and the public than any mere chemical analysis.

I am, Sir, yours, &c.,

1 Bedford Square,
Feb. 3, 1883.

JAMES HOGG.

Obituary.

JAMES STARK, F.F.P.S.G.

ON the 30th ult. there died at Glasgow, aged 69, a surgeon to whom is due the adaptation of thermo-cautery to many purposes it has served in modern times. Mr. James Stark was born at Camelon, near Falkirk, in 1814, and was educated at Glasgow, being admitted a Licentiate and Fellow of the Faculty of Physicians and Surgeons of that city on completion of his curriculum. Mr. Stark has at various times introduced several improved forms of surgical instruments to the profession, but the chief of these is undoubtedly the electric thermo-cautery, by which, with the aid of platinum points and a battery of manageable size, all the advantages of the cautery could be secured with a minimum of inconvenience. The deceased surgeon has always, since he commenced to practise his profession, enjoyed a generous share of public support; as a Temperance advocate he was well known and respected; and in connection with the Volunteer movement, he has from its inception been a staunch supporter of it. His loss is very greatly deplored, not only by his professional brethren, but by all who enjoyed his friendship.

DR. GEORGE FAIR.

THE death of this gentleman is announced as having occurred at Buenos Ayres. Deceased had only attained to middle age, having graduated at the University of Edinburgh in 1850. As soon as he was qualified, he volunteered for military service during the Crimean War, and after enduring the privations and sufferings entailed on all engaged in that campaign, he was honourably mentioned for his especial care of the wounded when under fire and in hospital, and received the Legion of Honour. Soon after the close of the war, he decided to settle in practice at Buenos Ayres, in South America, where his father had formerly owned a large tract of land and his two elder brothers were merchants. His general manner and marked abilities soon gained for him a wide circle of friends and an extensive practice. One of the South American journals, in summing up the record of his life, says:—"Whether as the director of the British Hospital or as a private practitioner, he was as distinguished in his profession as unceasing in his beneficence. While the rich gained health under his hands, his gratuitous services to the poor equally occupied his time. Latterly, when in weaker health, he was usually accompanied by his devoted wife, who went hand-in-hand with him in the work of his life, and in death they were not divided, and 'after life's fitful fever, sleep well' on the banks of the great water."

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column

ularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

"MEDICAL REFORM."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The appalling fate of the unfortunate Dr. Edwardes, your truthful rendering of the incidents and characters of the actors, including "the man Garrett," connected with the tragedy, and the apparent drowsiness of the legal authorities and the country at large now that the inquest is over, compel me to ask what is the General Medical Council doing, or about to do, with the evidence collected by its recent "Commission" under the chairmanship of Dr. T. K. Chambers?

There was some noise and blowing off of steam when the Commission commenced its inquiries; but judging from results so far, one is tempted to say of it—*Ex nihilo nihil fit*. Perhaps Egypt, Ireland, and the alleged "conspiracies to murder" have blocked up "Medical Reform" for another decade. Well, be it so. Let us hope on, or sleep on, and "rest and be thankful."

I am, Sir, yours truly,
J. O'F.

Houghton-le-Spring, Durham,
Jan. 30th, 1883.

P.S.—Since writing the above, a prescription by a "doctor's doctor" (unqualified) has been handed to me. I send a copy of it, as the original is too valuable to be parted with, as other colliery doctors might wish to treat bruises, broken bones, &c. on the same lines:—
℞ Tinct. fer. perchlor., ʒiij;
Aque ad ℥ss.

Sig.—A teaspoonful in water thrice daily.—F. H. C.

THE FOUNDER OF COTTAGE HOSPITALS.—The Hon. Secs. to the Napper Testimonial Fund request us to announce that the presentation will take place in the Rooms of the Society of Arts, on Saturday next, at 4 p.m., Mr. Erichsen, F.R.S., in the chair. All subscribers are invited to attend.

THE ARMY HOSPITALS INQUIRY.—A special meeting of the members of the Committee, under the presidency of Lord Morley, was held yesterday at Aldershot, when all the Commanding Officers of Regiments and Corps in the Garrison were examined.

DELIRIUM TREMENS.—A telegram from New York states that a terrible scene was witnessed in the Alcoholic Ward at the Bellevue Hospital. A machinist of immense muscular power, during an attack of delirium, killed another patient with repeated blows from a stool. Subsequently there was a fierce fight between the maniac and seven keepers, pieces of furniture being used, until the maniac was finally bound and subdued. His injuries are likely to prove fatal.

O. K. M., DR. S., and J. T. will please accept our best thanks for the trouble they have taken in obtaining and forwarding information concerning the subject of our recent notes on objectionable advertisements.

DR. ROBERTS.—The Society possesses rooms of its own, which are situated at 10 Adelphi Terrace, and afford the ordinary club accommodation. The annual subscription is one guinea, and members incur no liability whatever beyond this amount.

DUBITANS enters on a question in his letter which is at present closed for discussion, and cannot be reopened until certain points have been definitely settled.

H. N.—See reply to Dr. Roberts above.

LISMORE UNION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been directed to a "Note" in your paper of the 24th ult. headed, "The Lismore Union Case," in which my conduct is arraigned, together with that of the Local Government Board and the Guardians in general in relation to the late removal of the medical officer of the workhouse.

As far as these strictures relate to myself, though wholly unwarranted, I desire to pass them without further notice; but I think it right to correct an error into which you have been led through a mistake in the report of the recent proceedings of the Board of Guardians from which you quote.

It is alleged in your remarks that the medical officer was got rid of "ostensibly" because "he could not get on" with the fever hospital nurse and the master of the workhouse; and a late charge made against the fever hospital nurse is referred to as showing how unworthy she must be of the confidence of the Board. In point of fact, the charge of misappropriating the workhouse property was made, not against the *fever hospital nurse*, but against the *infirmary nurse*—an official who always enjoyed the full confidence of the late medical officer, and as regards whom it is only right to say no previous complaint had been made.

I am, Sir, your obedient servant.

Lismore, Feb. 1st, 1883.

F. E. CURREY.

[We should be interested to know whether it is the fact that the gentleman who was recently acting as *locum tenens* for the medical officer of Lismore Workhouse, who resided four miles away, was obliged to resign office because of the frequency of the calls which he received from the master? and whether it is also the fact that the said gentleman had previously declined to recommend the Guardians to put the workhouse officers on a money allowance in lieu of the meat supply to which they were entitled?—Ed.]

MEETINGS OF THE SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.—This evening (Wednesday), Feb. 7th, at 8 p.m. Annual Meeting. Election of Officers and Council. Specimens will be shown. President's Address.—Dr. Godson, Clinical Cases of Interest, with Remarks thereon.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—This evening (Wednesday),

Feb. 7th, at 8 p.m., Deputy Surgeon-General A. C. C. De Renzy, The Sanitary State of the British Troops in Northern India.

PHARMACEUTICAL SOCIETY OF LONDON.—This evening (Wednesday), A. W. Gerrard, A Research on the Alkaloid Gelsemine and some of its Crystalline Salts.—Dr. Thresh, Aromatic Spirit of Ammonia.—W. R. Dunstan and F. W. Short, An Apparatus for Continuous Extraction; the Assay of Nux Vomica.—W. R. Dunstan and F. Ransom, The Constitution of Liquor Sodæ Chloratæ; the Action of Chlorine upon Solutions of Sodium Carbonate.

ACADEMY OF MEDICINE IN IRELAND (Sub-Section of State Medicine).—Thursday, Feb. 8th, Opening Address by the Chairman.—Dr. Grimshaw, On Some Points concerning the Relations between Census Statistics and Health Statistics.—Dr. C. A. Cameron, On Antiseptic Experiments in a Mortuary Vault.—For Exhibition: Models and Specimens illustrative of Recent Sanitary Improvements, explained by Mr. W. R. Maguire. The collection includes the following: Patent Safety House Drain; Model Sections of Dwelling-house, showing arrangements, sanitary and insalutary.

CLINICAL SOCIETY OF LONDON.—Friday, Feb. 9th, at 8.30 p.m. Mr. Shuter, On Subperiosteal Amputation at the Hip-joint.—Mr. B. May, On a Case of Nephrolithotomy; Stone weighing 478 grains; Complete Recovery.—Dr. J. K. Fowler, On Two Cases of Pseudo-hypertrophic Paralysis in Adults (patients exhibited).—Mr. Godlee, On a Case of Fracture of the Radius and Dislocation Forwards of the Ulna at the Wrist, in which the Lower End of the latter Bone was removed to effect Reduction (patient to be shown).

ACADEMY OF MEDICINE IN IRELAND (Surgical Section).—Friday evening, Feb. 9th.—Living Specimens: Mr. H. Swamy, A Case of Cure of Glaucoma by Sclerotomy.—Dr. J. H. Benson, A Case of Diffuse Hypertrophy of the Breasts.—Mr. Stokes, Ununited Fracture of Humerus treated by Resection and Metallic Suture.—Mr. Croly, Cases of (1) Excision of Shoulder; (2) Excision of Wrist; (3) Excision of Elbow; (4) Excision of Knee; (5) Double Hare-lip, without Cleft Palate.—Mr. Wheeler, Cases of (1) Excision of Knee; (2) Excision of Elbow.—Mr. Kendal Franks, Case of Excision of the Elbow.—Specimens exhibited by card: Mr. Thornley Stoker—1. Cast of Compound Dislocation of Ankle, requiring Amputation; 2. Cast of Bilocular Patellar Bursitis.—Mr. Wheeler, Portions of Tibia, Femur, and Patella removed from living specimen present; 2. Portions of Ulna, Radius, and Humerus removed from living specimen present; 3. Head of Humerus excised for Carious Disease.—Mr. Thomson—1. Large Fatty Tumour removed from the Arm; 2. Nasal Polypus removed by Lateral Section of the Nose.—Mr. Croly, Casts of Rectangular Flap Amputations (Teale) of Thigh, Leg, and Arms; Syme's and Chopart's Amputation of Foot.—Mr. Kendal Franks—1. Sarcoma of the Foot; 2. Mammary Tumour; 3. Portions of Humerus, Ulna, and Radius removed by Excision.—Mr. Stokes—1. Greater Portion of Lower Jaw removed by Excision for Epithelioma; 2. Photograph of Patient after Operation; 3. Photograph of Case of Ununited Fracture of the Humerus.—Papers: Mr. T. E. Little, On a Case of Ligature of the Subclavian Artery.—Mr. M. Kilgariff, Cases of Strangulated Hernia.—Mr. Kendal Franks, On Spontaneous Dislocation of the Elip.

HARVEIAN SOCIETY OF LONDON.—Thursday, Feb. 15th, at 8.30 p.m. Discussion on the Report of a Committee of the Society appointed for the purpose of inquiring into the Mortality referable to Alcohol, to be opened by Dr. Morton.

ROYAL INSTITUTION.—We are requested to announce that Dr. W. H. Stone will give the first of three lectures on Singing, Speaking and Stammering, on Saturday, Feb. 17th; and Professor R. S. Ball will give the first of four lectures on the Supreme Discoveries in Astronomy on Tuesday, Feb. 20th.

Vacancies.

Kensington Dispensary.—Resident Medical Officer. Salary, £135, with apartments, &c. Applications to be sent to the Hon. Sec. 20 Stanford Road, Kensington Square, by Feb. 10th.
Salford Royal Hospital.—District Surgeon for the Pendleton Branch Dispensary. Salary, £80, with board and lodging. Applications to be sent to the Secretary on or before Feb. 15th.

Births.

DUKE.—Jan. 25th, at 74 South Circular Road, Dublin, the wife of Mansergh P. Duke, L.R.C.S.I., of a daughter.
EVANS.—Feb. 1st, the wife of Dr. Lewis Evans, 11 Crescent Place, Clapham Common, of a son.

Marriages.

POETT-SHERIDAN.—Jan. 29th, at St. Audeon's Church, Dr. P. M. Poett, of Terenure Road, to Thomasina, daughter of the late Henry Sheridan, Esq., Usher's Island.
WHITE-FERROTT.—Jan. 30th, at Monkstown Church, Hugh Brady White, Surgeon-Major, A.M.D., to Marlon Isabella, only daughter of John W. Perrott, Esq., of Thorncliffe Monkstown.

Deaths.

BROWN.—Jan. 28th, at his residence, Ryde, Isle of Wight, Richard Brown, M.D., late of Cobham, Surrey, aged 61.
DUGAN.—Jan. 25th, at Gainsborough, J. P. Dugan, M.D., aged 61.
GAUNT.—Jan. 19th, at his residence, Alvechurch, Worcestershire, John Smith Gaunt, M.R.C.S., aged 65.
JOHNSTON.—Feb. 2nd, at Tunbridge Wells, W. Woods Johnston, M.D., late of Java, and of Prince's Square, London.
SAVAGE.—Jan. 27th, at Dover, Johnson Savage, M.D., Deputy Inspector-General of Army Hospitals, aged 79.
SINCLAIR.—Feb. 1st, at Capenhurst, near Chester, Helen Gertrude, daughter of James Sinclair, M.D., Lytham, aged 24.
THOMAS.—Jan. 16th, at The Cliff, Goodwick, Fishguard, John Richard Thomas, Surgeon-Major, F.R.G.S.

dilated, but hypertrophied. The wall of the auricle may be increased in thickness from its normal of about 3-20ths of an inch (Bouillaud) to $\frac{1}{4}$ of an inch or more. I have found it $\frac{1}{4}$ of an inch thick in the case of mitral stenosis in a child. On the other hand it is occasionally found dilated rather than hypertrophied. In one case I found it extremely dilated, and the walls almost as thin as an ordinary visiting card. The dilatation and hypertrophy of the left auricle are also in accord with *a priori* consideration, for the cavity becomes over-filled on account of the obstruction to its outflow and the muscle has a heavier task than the normal in aiding the filling of the ventricle. When dilatation is in excess it is through an unusual failure of muscular power.

I turn now from the morbid anatomy to the *clinical history* of mitral stenosis, and I shall ask your indulgence if I seem to dwell too long upon points which may not seem at first sight to have a very distinct bearing upon treatment. I feel sure that I shall have your concurrence when I say that no disease is well treated that is misunderstood. We have a great deal to learn as to mitral stenosis; it is, I feel quite sure, in many instances unrecognised, not from any fault in observers, but from their misfortune. It is only comparatively recently that our pupils could be taught in our hospitals the methods of discriminating between cases of mitral stenosis and those of mitral regurgitation, and it is unwise to conceal the fact that difficulties in differential diagnosis do occur. But it has, to my mind, been too hastily assumed that the consecutive changes and collateral phenomena in the two conditions are so closely similar that a plan of treatment for the one is equally applicable to the other. I need not ask you to concur with me in deprecating the plea of *cut bono*? It is our bounden duty to know all we can of the disorder we have to treat, even if the immediate influence of such knowledge upon treatment be not so very apparent.

Let us consider the signs by which we may recognise the condition of mitral stenosis. 1. *The murmur.* This is heard in the neighbourhood of the apex of the heart, in the mitral area, but according to my experience usually rather to the right of the apex. It occupies the diastolic period—the long pause—usually the concluding portion of it, and then it terminates abruptly with the first sound. It is chiefly M. Fauvel, of Paris, and Prof. Gairdner, of Glasgow, that we have to thank for accurately describing this murmur and making it available for the practical purposes of diagnosis. The distinction between a murmur indicating mitral stenosis, and that indicating mitral regurgitation is to be made partly by the character of the sound and partly by the rhythm. The stenosis-murmur is usually of a rattling and rolling character, but its chief characteristic is its abrupt termination—it ends with a sudden stop as the murmur of regurgitation *never* does. Even when the murmurs of stenosis and regurgitation are combined there is usually a spot in the neighbourhood of the apex at which the former is heard to stop suddenly, and the systolic murmur to “tail off” from it. The rhythm is determinable by ascertaining the relation to the second sound, and to the impulse of the heart. In approaching the apex from the base one may be convinced of the commencement of the murmur after the second sound. Near the apex one may hear that the termination of the murmur is with the impulse of the heart as felt upon the chest wall or where this cannot be determined with the pulsation of the carotid in the neck. Such are very briefly the chief characters of the murmur which is so commonly known as the presystolic murmur that has been considered to be almost, if not absolutely, pathognomonic of mitral stenosis. And now as to its mode of production and position, which is really of practical importance. Professor Gairdner and others have considered it due to the muscular contraction of the auricle urging the blood through the stenosed aperture into the ventricle. It is well known that Prof. Gairdner proposed the term auriculo-systolic to describe the murmur. Dr. Wilks, however, (a) considered that the murmur might anticipate the auricular systole; that it might occur “not only during the contraction of the auricle, but also during the heart’s diastole and pause.” Dr. Galabin came to a like conclusion from the evidence afforded by the cardiograph. I am able to afford the crucial proof of the view that the causation of the presystolic murmur may be independent of the auricle—*first*, because in many cases I have observed that, though there has been present a prolonged presystolic murmur commencing in the long pause almost immediately after the second sound, cardiographic

evidence has shown the auricular systole to occupy its normal position, just anterior to the commencing contraction of the ventricles; (a) secondly, because I observed a case in which a murmur occupied at one time a portion of, and at another almost the whole of, the long pause, and the autopsy showed that the auricular systole would have had no share in producing such a murmur, for not only was the left auricle *so* dilated that it could have exerted no appreciable muscular power, but it was lined by a closely-adherent old laminated blood-clot. I consider that it is clearly proved that the so-called presystolic murmur may occur during the diastolic as well as the presystolic period, and that it may be due to the entrance of blood into the ventricle directly diastolic relaxation permits, the blood being urged through the stenosed aperture owing to the tension under which it has been retained in the elastic and distended auricle and the pulmonary veins. The contraction of the auricle may reinforce the murmur, and make it loudest just before the ventricular contraction. This consideration explains why, in exceptional cases, the murmur of mitral stenosis is post-diastolic, and ceases with a distinct pause before the first sound, the auricular systole in such cases being weak or imperfect. It is certain that in a large majority of instances the presystolic murmur serves to indicate with precision the existence of mitral stenosis. The late Dr. Hayden has said: “It is *never* present where mitral narrowing does not exist, and it is *never* absent, and that only for a very limited period in cases of that lesion.” (b) I am sorry that I cannot concur in so positive a statement. In a few cases I have found the presystolic murmur closely simulated by the murmur of aortic regurgitation when this is conducted towards the apex, and especially, as is sometimes the case, when it is heard *only* in the mitral area. Cases have been recorded in which a presystolic murmur has been noted during life, and the autopsy has demonstrated not mitral stenosis, but aortic regurgitation. Another possible source of error is the existence of pericarditis, when friction may be occasioned by the auricle, and cease at the moment of systole. Again, I think most observers will agree that, in some cases, the presystolic murmur is extremely variable. It may be inaudible during repose, and yet very evident when the patient is made to manifest some slight exertion. Again, it may be absent for considerable periods, and then be readily discoverable. Although, therefore, I consider that in the great majority of cases the presystolic murmur declares with precision the existence of mitral stenosis, it is necessary to consider other signs before committing oneself to a positive opinion.

Another auscultatory sign of great importance in indicating the obstructive lesion is *reduplication, or a seeming reduplication, of the second sound of the heart.* This phenomenon is to be noted in at least a third of the cases of mitral stenosis, and only rarely in other conditions. It becomes, therefore, a valuable aid to diagnosis. I have formerly developed before the Society at length my views as to the mode of production of this seeming reduplication. (c) I will only say here that I believe it to be due, not to any want of synchronism in the closure of the aortic and the pulmonary semilunar valves, but to the normal second sound followed by another sound, due to a sudden tension of the mitral valve itself. The blood, accumulated under pressure in the auricle, rushes through the stenosed aperture as soon as diastolic relaxation permits, and jerks the mitral curtains, or the thickened material which represents them on the ventricular aspect; this gives rise to a sound of tension which, coming closely after the normal second sound, appears like a reduplication of the latter. The great anterior flap of the mitral valve is normally on the stretch in diastole; in Dr. Macalister’s words, “it does not hang loosely down; it is stretched taut from basal ring to muscle tip.” (d) It does not seem difficult to realise that in the condition of stenosis, and for the reasons given, this diastolic tension may be so increased as to give rise to sound.

A third sign of importance in establishing the diagnosis of mitral constriction is *thrill.* A thrill at the apex is rarely met with in mitral regurgitation, but very commonly in mitral stenosis. Its rhythm is determinable in like manner with that of the murmur, and if it be presystolic the diagnosis of mitral constriction is assured. I have observed presystolic thrill where there has

been no presystolic murmur, and where the condition of stenosis has been indicated by other signs.

A fourth means of differentiation is the determination by percussion of the outline of the heart. If this be done accurately, by means of a pleximeter, and marked upon the chest wall with a copying pencil, a transfer may readily be taken upon paper and kept for reference. By this method I have shown in some cases—1. An abnormal bulging in the situation of the left auricle; 2. A dilatation of the right cavities and of the pulmonary artery; 3. An absence of dilatation of the left ventricle. The concurrence of these signs has strongly suggested the diagnosis of mitral stenosis when other signs have been obscure.

Lately, a valuable aid to diagnosis may be received from the employment of the sphygmograph and cardiograph.

Very contradictory opinions have been put forth as to the pulse of mitral stenosis. Dr. Hayden considered that "the pulse of mitral obstruction is usually quite regular, not above ninety in the minute, but small," that is, until the later stages when failure commences, and Dr. Fagge thought that in the majority of cases in which a presystolic murmur was heard the pulse gave no indications of the existence of disease. A large number of diseases, however, have noted irregularity of the pulse as pertaining to mitral constriction. (a) My own observations point to a notable irregularity of the pulse in mitral stenosis; and this in such degree as to afford valuable diagnostic evidence. In mitral regurgitation the pulse is usually regular until compensation is beginning to be imperfect, and the right chambers begin to yield. In mitral stenosis, however, irregularity may be evident when compensation is perfect. It is true that many observations may be made with a record only of an even and regular pulse; but then the peculiarity of mitral stenosis becomes manifest in the trace, a double or even a triple pulse is recorded before the base line of the sphygmographic trace is reached. These pulsations are due to repeated systoles, the normal correlation between auricle and ventricle being disturbed. In the later stages when the right side of the heart commences to fail, irregularities in volume of the pulse may be observed, and in a case where there was great dilatation of the auricle, I found the pulse become extremely slow, its rate falling from 80 to 56, and then to an average of 40 per minute. At one time it was 36.

The evidence afforded by the cardiograph, when mitral stenosis is suspected is, in my opinion, extremely valuable. The trace enables one to judge of the relative length of systole and diastole. In free mitral regurgitation a very short interval separates the systoles; the duration of the systole, instead of being as in the normal, less than that of the diastole, is greater. In stenosis, on the other hand, the interval between the systoles may be greatly prolonged. Or in stenosis the diastolic intervals may be observed to vary greatly in duration, several systoles may occur with no appreciable diastolic interval, and another interval may be abnormally protracted. Much more characteristic, however, is the appearance of a number of vibrations in the diastolic part of the trace—in fact, the vibrations which are heard by the ear as murmur, or felt by the finger as thrill, may be written on the smoked paper by the needle of the cardiograph. I show you many examples. In some it will be seen that the diastolic portion is serrated and there is no indication of the elevation indicating the auricular systole preceding the main upstroke indicating the grasp of the ventricle; in others, vibrations are seen to precede a defined systole of the auricle; in a third set, the auricular systole is well marked and the sonorous vibrations of murmur, though murmur existed, are not recorded. So I think we have a means of determining in some measure the degree of constriction. If such were considerable it is unlikely that the auricular systole would be readily transmitted and recorded; on the other hand, it is likely that the finely serrated line of vibrations would be produced by the extrusion of blood through the narrowed aperture. Some of my tracings show in a marked manner the effect of effort in rendering evident vibrations in the diastolic portion which were not visible during repose. By a comparison too of the characters of the systolic and diastolic portions, I think we are enabled to obtain some indication whether in combined stenosis and regurgitation the former predominates over the latter, or otherwise, or whether or not hypertrophy predominates over dilatation of the ventricle.

Such are the chief means at our command for arriving at a diagnosis of mitral constriction, and though I do not think we are justified in coming to a conclusion from obser-

vation of one sign alone, I think by a judicious combination of methods of observation no case of mitral stenosis ought to go unrecognised.

I pass on now to consider the clinical evidence as to the origin and course of the morbid changes which bring about the obstructive lesion. We are at once met by a body of evidence which shows that mitral stenosis, like mitral regurgitation, has a strong relationship with rheumatism. From the morbid anatomy standpoint it has been supposed that, at least in some cases, the lesion might have been congenital. The smooth surface of the septum between auricle and ventricle, with its symmetrically-edged aperture, might *prima facie*, support this view; but we do not find the lesion commonly associated with those which are undoubtedly congenital, and these are, moreover, infrequent in the left, though frequent in the right chambers of the heart. In one of the twenty post-mortems, however, which I have recorded, a large permanent foramen ovale was present, the subject being a female, *æt.* 50. It is known that such congenital disease, as Dr. Peacock formerly pointed out, predisposes to endocarditis, and it is probable that such was the sequence in this case, for we are met by many observations to show that those lesions of stenosis, which in appearance suggest a congenital causation, are met with in cases which are undoubtedly rheumatic.

Dr. Dyce Duckworth has collected the records of 264 cases of mitral stenosis from various sources, including eighty observed by himself, and the figures show that 141, or 60·8 per cent., manifested in some form rheumatic antecedents. Of sixty-four cases observed by myself, and of which I have records, exactly thirty-two (50 per cent.) had been the subjects of rheumatic fever, subacute rheumatism, and rheumatoid pains. The association, therefore, of mitral stenosis with rheumatism is an intimate one. When we come to inquire, however, as to the degree of such association comparatively with that subsisting between mitral regurgitation and rheumatism, I think we shall find the relationship less marked in the one case than in the other, and I hope that the inquiry will not be unfruitful as regards the determination of the nature of the change which induces mitral stenosis. If I take the cases of mitral regurgitation derived from the same sources (*viz.*, private and hospital practice) from which I obtained the cases of mitral stenosis which I have mentioned, I find that of 123 cases 73 or 59 per cent. presented evidence of rheumatism in their history. But it must be recollected that in a considerable number of the cases of regurgitation organic disease was not present or not proved, whilst mitral stenosis is always due to organic change. It follows that the figures do not sufficiently express the relation between rheumatism and the organic change which induces regurgitation at the mitral orifice. In the analysis of cases of cardiac disease prepared from the records of the London Hospital by Dr. Gabbett for the year 1880, it will be seen that whilst 53 per cent. only of the cases of mitral stenosis presented history of rheumatism, 77 per cent. of the cases of mitral regurgitation were rheumatic.

And now, to push this question further, let us inquire as to the degree of manifestation of rheumatism in the two classes of cases. First, as to the relation with acute rheumatism. If we examine the records of acute rheumatism in the London Hospital for 1880 and 1881, we find that the proportions of cases of mitral stenosis (including those in which stenosis was combined with regurgitation) stand thus: Proportion of all cases in a first attack of acute rheumatism, 5·6 per cent.; in patients suffering a second attack, 3 per cent.; in those with a history of two or more previous attacks, 1·7 per cent. It is obvious that this relationship differs very widely from that existing between mitral regurgitation and acute rheumatism, where the proclivity to the lesion increases with the attacks. It is obvious, therefore, that a close relation does not obtain between mitral stenosis and the acute forms of rheumatism, and that repeated attacks do not tend to produce the lesion.

As a further step towards the elucidation of the question, I will now ask you to follow me in the inquiry as to the etiology of mitral stenosis in the cases of children. I think you will agree with me that a considerable light can be thrown on the subject from this source. Contradictory opinions have been enunciated as to the proclivity of children to the affection. Dr. Hayden thought that it was to be met with most frequently in children; while Dr. Fagge had no patients under 10, and the youngest observed

(a) See list in Balfour's "Clinical Lectures on Diseases of the Heart," Second Edition, p. 123. London; J. & A. Churchill, 1882.

by Dr. Dyce Duckworth was 14. The cases I shall now ask your attention to were all under 12 years of age; I have had many who were seven years old. I have tabulated these cases according to the degree of manifestation of rheumatic symptoms. In those who suffered from *acute rheumatism* I found 24 cases of mitral regurgitation to 1 of mitral stenosis. In those classed as subacute rheumatism, 13 of mitral regurgitation to 2 of mitral stenosis. In those who suffered only rheumatoid pains, 6 of mitral regurgitation to 2 of mitral stenosis. So far as this evidence goes, therefore, it tends to show that it is not the more severe but the slighter forms of articular rheumatism which were attended with the obstructive lesion; whilst the opposite is the case as regards the regurgitant. To pursue the point where the rheumatic tendency is not so obvious, but where, as I have said in my first lecture, a rheumatic form of endocarditis is, nevertheless, manifest, we will consider the cases occurring after scarlatina and measles. In cases presenting a history of scarlatina, I found 13 cases of mitral regurgitation to 2 of mitral stenosis. In those with a history of measles, 12 of mitral regurgitation to 2 of stenosis. Lastly, in the case of children in whom no history of rheumatism was manifest, nor any disease which we might suppose to be likely to induce endocarditis. In these I found 24 cases of mitral regurgitation to 14 of mitral stenosis. It is obvious, therefore, that the proclivity to the obstructive lesion is in a very marked manner greatest where articular phenomena are not manifest at all. It might be thought that this was evidence rather against the view that rheumatism is a cause of mitral stenosis; but, as I have shown in my former lecture, the advent of endocarditis having the essential characters of that associated with rheumatism may be so insidious that no subjective sign marks its onset; and we have found in many instances that the course of the affection in the non-articular cases, and the morbid changes as shown by post-mortem examination on the fatal cases, do not differ in any appreciable way from those which are manifest in cases that have a distinct history of rheumatic causation. It would, therefore, appear most probable that the correct conclusion is, not that mitral stenosis is independent of rheumatism, but that it is associated with the less pronounced forms of it—with its insidious, and not, so to speak, with its *explosive* varieties.

And now let us consider the evidence which clinical observation affords us of the mode of onset of the obstructive mitral lesion. I will give, as briefly as possible, some cases illustrative of the various ways in which the clinical signs indicate the disease to arise.

(To be continued.)

DANGEROUS HÆMORRHAGE FROM THE EXTERNAL GENERATIVE ORGANS DURING LABOUR. (a)

By PETER YOUNG, M.D., F.R.C.P.E.,

Lecturer on Midwifery and Diseases of Women in the Edinburgh School of Medicine; Physician Accoucheur to the Edinburgh Royal Dispensary.

In the great majority of cases, bleeding during or after labour is intra-uterine, and is readily controlled by supra-uterine pressure. Sometimes, however, when this bleeding has its origin from a tear in the cervix, this treatment does not suffice, and plugging of the vagina in the first instance, at all events, is urgently required. Occasionally, but still more rarely, alarming and even fatal hæmorrhages may occur from laceration of the vulvar orifice at the vestibule. The submucous tissue between the urethra and the clitoris consists largely of spongy erectile structure, and when torn, even to a moderate extent, is apt to bleed profusely. Of the latter form of hæmorrhage he gave the histories of two cases.

In the first case, a multipara, which was attended by a midwife; he was called in owing to persistent bleeding after the child and placenta were expelled. When seen,

the patient was almost pulseless and deadly pale. The uterus was firmly contracted, and the bleeding had ceased. To ensure immunity from further loss of blood the vagina was plugged, and a firm compress laid on the vulva. Notwithstanding the vigorous application of the usual restoratives, the woman died in a few minutes, and before arrangements could be made to perform transfusion.

On post-mortem examination the source of bleeding was found to be a tear at the upper margin of the vulvar orifice, extending from the left side of the urethra up towards the clitoris. Numerous venous sinuses and two or three small arteries were lacerated.

In the second case, a primipara, the child was born a few minutes before Dr. Young's arrival. The patient was pale and anæmic, and in a fainting condition. The uterus was firmly contracted round the placenta, and the bed-clothes saturated with blood. On exposing the vulva, blood was seen flowing freely from the neighbourhood of the symphysis, which was at once checked by placing the finger on the spot and exercising steady pressure against the subjacent bone. The expulsion of the placenta was proceeded with in the usual way, the finger being still kept applied to the bleeding part. On careful examination the vestibular tissue was found lacerated much in the same way as in the first case. To prevent further hæmorrhage a couple of metallic sutures were inserted, and a compress of cotton applied. The sutures were removed on the seventh day. The patient made a good but slow recovery. In these cases it is to be noted that pressure on the uterus increases the hæmorrhage, owing to the free anastomoses of the veins of the generative tract and the absence of valves; local pressure and the application of styptics in the slighter cases are the only means of stopping the bleeding. With regard to the etiology, the lacerations were probably due partly to the rapid expulsion of the child's head, but chiefly to a friable condition of the vulvar tissues.

RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S. Eng., M.S. Lond.,
Surgeon to the London Hospital.

PART II.—*Reported Cases of Recovery—Treatment—Conclusion.*

(Continued from page 115.)

6. ABDOMINAL SECTION and sewing up the rent in the bladder were discussed by Benjamin Bell and warmly advocated by Dr. Blundell. (a) The latter proposed that cases of intra-peritoneal rupture of the bladder should be treated by opening the abdomen, washing out the peritoneal cavity with water at a temperature of 98° Fahrenheit, fishing up the bladder, putting a ligature round the aperture in its wall and allowing one end of the ligature to hang out of the abdominal wound. To determine the value of his suggestion, he experimented on rabbits. Four ounces of urine were injected into the peritoneal cavity, and allowed to remain an hour. The fluid was then withdrawn, and the cavity well washed out with tepid cistern water. Three out of four rabbits died with general peritonitis, and one lived. In another class of experiments he tied up the fundus of the bladder, afterwards cutting the fundus away. The ligatures came away in a few days, leaving the bladder closed. In 1857 Dr. Gross proposed abdominal section for the removal of the effused urine; and more recently Mr. Holmes has suggested opening the abdomen, removing the urine, and sewing up the rent in the bladder. Mr. Willett (b) and Mr. Heath (c) have

(a) Abstract of paper read before the Obstetrical Society of Edinburgh, January 31, 1883.

put this method in practice without saving the patients. Both cases are valuable and instructive in the highest degree. In Mr. Willett's case an incision, five or six inches in length, from the umbilicus to the pubes was made in the mesial line through the parietes; and at once several ounces of dull brownish fluid, with strong urinous odour escaped. The intestines greatly distended, bulged out of the wound, and were protected by warm flannels. About half-a-pint of urinous fluid was removed from the pelvis, but a small quantity seems to have eluded the operator in the upper part of the cavity. The intestines were carefully cleaned before they were replaced. The rent in the bladder, which was a straight tear above, but jagged and uneven below, was sewn up by means of eight interrupted sutures of fine Chinese silk, placed at intervals of rather less than half-an-inch. The sutures appeared to close the rent completely. A carbolised drainage tube was passed into the pelvis through the lower angle of the abdominal wound, and secured in that position. A Thompson's catheter was introduced and retained in the bladder. After the operation the patient remained free from pain and sickness till the following day, when both recurred. He died rather suddenly twenty-two hours after the operation. At the post-mortem examination Mr. Willett found that, notwithstanding the care he had exercised, the rent in the bladder had not completely closed; for between the two posterior stitches there was an orifice, through which water injected *per urethram* escaped very freely. Except at this spot the edges of the wound were adherent. Mr. Willett thinks that the patient's life was not prolonged, but shortened by the shock of the operation.

Mr. Heath's case was operated on at 4 p.m.—42½ hours after the accident. "An incision was made in the middle line just above the pubes for two inches, and the tissues were divided down to the peritoneum, which appeared blue; the recti muscles, which were firmly contracted, being held aside by retractors with difficulty. The peritoneum was then picked up, and a cut made into it, when a gush of fluid like that drawn off by the catheter came out. A large quantity of clots was then taken out from the peritoneal cavity. Mr. Heath having introduced his finger found a long rent in the posterior wall of the bladder, high up. *It was proved to be a rent in the bladder by passing a catheter through it from the urethra.* The rent was then sewn up in the following way:—The first stitch was put in at the lower end of the opening by means of a needle set at right angles to the handle, and was then firmly tied; one end of the catgut being then used by an assistant to pull the bladder up out of the pelvis, Mr. Heath threaded the other end into an ordinary needle, and carefully sewed the opening up with a continuous suture, a great part of which is still visible in the preparation. The clots were removed as far as possible from the peritoneum, and the cavity sponged out after injection with warm water; and a long, large-sized drainage tube was inserted at the lower angle of the wound, which was brought together by deep and superficial sutures. The carbolic spray ceased working before the operation was completed. A catheter was passed into the bladder, to which was afterwards attached some india-rubber tubing leading into a vessel under the bed. Patient being put back to bed, a hot poultice was applied to the abdomen, and opium was administered—*gr. j., in pil. 4tis horis.* At 11 p.m. patient expressed himself as much better. His anxious Hippocratic aspect had passed off; pulse had improved; no sickness; abdominal pain much less; distension relieved." He passed a quiet night, almost free from pain, and lay with his legs outstretched. The drainage tube was removed the day after the operation. The improvement in the patient's condition was maintained till the third day after the operation, when he complained of being blown up with wind. The following night he was very restless; constant vomiting set in, and he passed several

motions in bed. He got rapidly worse, and died rather more than four days after the operation, and six days after the accident. At the post-mortem, the recto-vesical pouch of peritoneum was found to contain about six ounces of clotted blood, black in colour, and moderately offensive in odour. The catgut suture had given way at the lower part of the rent in the bladder, which was gaping. The mucous membrane of the bladder was blood-stained.

Mr. Willett's patient would have had a far better chance of recovery if he had been operated on when first seen after admission into the hospital. Owing to a natural and laudable desire to be fully certain concerning the nature of the lesion, and to be morally supported by his colleagues in the application of an unusual procedure, Mr. Willett deemed it advisable to wait twenty-four hours. The operation then performed was, undoubtedly, a far more severe operation than Mr. Heath's; the incision being two or three times as long, and the intestines much exposed and handled. Moreover, the object of the operation was partly defeated by the small aperture left between the two lower stitches, much to Mr. Willett's annoyance and regret. To obviate this occurrence in any future case, Mr. Willett suggests distending the bladder after the insertion of the sutures and before closing the abdominal wound. A moderate injection of fluid would probably suffice for the purpose; a large quantity might put a dangerous strain on the stitches.

In Mr. Heath's case the operation was done at the earliest opportunity, but rather longer after the accident than in Mr. Willett's case; and its want of ultimate success may have been due partly to the unavoidable interval, partly to the presence of six ounces of decomposing clot left in the recto-vesical pouch, and partly to the giving way of the catgut sutures. Most probably the suture gave way on the third day after the operation, when the patient's condition markedly deteriorated. But though the patient died, the advantage of abdominal section is strikingly demonstrated by the great relief afforded to the patient. My second patient, who was treated only by the intermittent use of the catheter and opium, lived six days; but how remarkable the contrast between his suffering, restless state, with the constant vomiting and the condition of Mr. Heath's patient—almost free from pain, entirely free from sickness, passing quiet nights and days, and dozing with limbs outstretched. Surely this is a solid gain, and I am sorry that Mr. Heath, having all but attained the success which he deserved, instead of directing his attention entirely to the improvement of the method which he adopted with courage and sagacity, should, in a moment of discouragement, pin his faith to the airy fabric of washing out the peritoneum through the rent in the bladder, erected on the unstable foundation of Dr. Thorp's equivocal case. Abdominal section has not yet been fully and fairly tried. Twenty or thirty cases may be needed before the value of the method can be determined. Much will depend upon points of detail, the promptitude with which it is applied, the age and condition of the patient and severity of the injury, the more or less complete removal of urine and blood from the peritoneal cavity, the length of incision, the treatment of the wound in the bladder, washing out the peritoneum, and the establishment of drainage. It is necessary to insist on the earliest possible formation of a diagnosis and performance of the operation, and a thorough removal of urine and blood from the peritoneum.

(To be continued.)

WE have pleasure in stating that Dr. Palfrey, senior Obstetric Physician to the London Hospital, who has been confined to his room for the past two months, in consequence of a serious indisposition, has now completely recovered, and has resumed his professional duties.

AN ESSAY UPON HIP-JOINT DISEASE.

By S. D. CLIPPINGDALE, M.D., F.R.C.S.

*(Continued from page 117.)*V.—THE SYMPTOMS *(Continued)*.

3. *The Symptoms of the Third Stage.*—The local symptoms of the third stage are of two kinds: those referable to the changes in the joint after the fluid has escaped from it; and those referable to the changes in the tissues outside the joint, into which the escaped fluid passes. The constitutional symptoms of the third stage are such as may be caused by prolonged confinement to bed, or from protracted suffering, or from secondary complication of internal organs. The change from the second to the third stage in the local symptoms may be either sudden or gradual. Sudden, if the capsule gives way by a large rent, and the tissues outside the joint in a condition to receive the fluid; gradual, if only a small opening be made, and the tissues outside are matted together so as to hinder the escape of the fluid.

The cavity of the joint being empty, the articular surfaces come into contact; and then ensue those destructive changes in the cartilages, bones, and ligaments which characterise the advanced stage of the affection. The cartilages, at the time of rupture of the capsule, are probably destroyed by ulceration to some extent, and their protection to the underlying bone to the same extent lost. The bone is, therefore, attacked by the morbid process at every available spot. When the bones have come into close contact, perforation may occur if the head of the femur press upon the floor of the acetabulum, but dislocation if it press upon the rim. Contact of the carious bony surfaces gives rise to the peculiar grating produced by friction. Friction of the carious surfaces causes the greatest of pain, so that the patient is more than ever desirous of keeping the joint at rest; and in order to do this, he maintains the muscles of the thigh in a state of tonic contraction, and in this way the head of the femur is pressed firmly against the acetabulum. If this were permitted to continue, ankylosis would follow and a cure effected, but with the limb probably fixed in an awkward position.

When dislocation takes place, its evidence is, as a rule, plain. It occasions a visible change in the contour of the joint; the hip is widened and flattened; the head of the bone is to be felt in its new position; the movements of the limb are rendered more imperfect; abduction and rotation outwards are nearly impossible, and the limb is shortened, the amount of shortening being sometimes as much as two or more inches. Here it will be convenient to notice a subject which seems to have excited more attention than it deserves, and to have given rise to much curious speculation. I refer to the causation of real and apparent lengthening and real and apparent shortening.

Shortening and Lengthening, "Real" and "Apparent."

—To give an idea of the amount of attention which has been bestowed upon this subject, the following is reproduced from Chelius's "Surgery":—"The most different reasons have been assigned for the lengthening of the extremity, consequent upon the supposed expulsion of the head of the thigh-bone from its socket—for instance, accumulation of synovia (Pettit, Camper, and others); swelling and degeneration of the mass of fat, improperly called the synovial gland, in the hip socket (Valsalva, Monro, Van der Haar, De Haen, Vermandois, Schwenke, Oallisen, Fluck, Portal, Ficker, &c.); inflammation and swelling of the joint capsule (Duverney, Closius); swelling of the cartilage, round ligament and mass of fat (Boyer); swelling of the cartilage and periosteum of the head of the thigh-bone and of its socket (Falconer); swelling of the head of the bone from caries centralis (Rust); destruction of the lower edge of the hip socket (Langenbeck—in destruction of the upper

edge shortening is said to occur); relaxation and unnatural extension of the ligaments and muscles (Richter Schreger, Larry, Chelius); relaxation of the muscles (Fricke)." The above, then, are the opinions which have been held as to the causes of lengthening and shortening; but I would venture to suggest that all probable causes are contained in the short table below:

Probable causes of alteration in length of limb—

LENGTHENING.

<i>Real.</i>	<i>Apparent.</i>
Displacement downwards of head of femur.	Lowering of pelvis on affected side.

SHORTENING.

<i>Real.</i>	<i>Apparent.</i>
1. Dislocation upwards.	Pelvis raised on affected side.
2. Separation of epiphysis of head; rest of bone drawn upwards.	

Abscess, its Position and Symptoms.—A feature peculiar to the third stage is the presence of pus in the tissues, having formed there either without communication with the interior of the joint, or having passed there after rupture of the joint capsule. In its position an abscess may be either within or outside the pelvis.

(a) *Extra-pelvic Abscess* occupies principally the places of areolar tissue in the hip or thigh; and if the matter has escaped from the joint, then the direction the matter may take seems to be determined by the part of the capsule ruptured.

The situation of sinuses is a matter of some interest. It will be noticed that an abscess "points" by preference in certain places. Matter will travel along an inter-muscular layer of connective tissue for some distance to find an outlet to the surface, rather than perforate the muscle that lies above it. It therefore frequently approaches the surface at a point where two muscles diverge. Thus, pus escaping from the anterior part of the hip-joint passes downwards between the pectineus and psoas magnus, over the crureus, and beneath the rectus femoris. The rectus is, then, the only muscle which hinders the escape of the matter to the surface of the limb. To reach this it escapes either by the outer or the inner border of the muscle. Two muscles prevent this in the upper part of the thigh—viz., the tensor vaginæ femoris on the outer side, and the sartorius on the inner side. Where these two muscles diverge from the rectus the matter has a chance of escaping to the surface, and it is at places corresponding to the divergence of these muscles that sinuses will be found. In the nates the sinuses are over the lower border of the gluteus maximus, beneath which the matter escapes.

An extra-pelvic abscess may point in an unusual place, as upon the outer side of the knee, near the ankle, or by the side of the tendo achillis. The course an abscess may take is sometimes remarkable. In a case recorded by Dr. Adams, of Dublin (before referred to), the matter escaped through a perforation in the rim of the acetabulum, entered the substance of the psoas muscle, and passed upwards to the spine. And in the same case a second abscess passed into the pelvis through the thyroid foramen, and was traced as high as the bifurcation of the abdominal aorta, and here it was found to have perforated the vena cava, and in this way blood had appeared in the pus. Mr. Smith states that Sir Astley Cooper also had a case in which blood was mixed with the pus, the cause here being penetration of the femoral artery.

(b) *Intra-pelvic Abscess.*—Pus generally enters the cavity of the pelvis through a perforation in the acetabulum, but it may do so also through the sciatic notch, or through the thyroid foramen. Pus probably does not pass through a perforation in the acetabulum as soon as such perforation has been made, for this is blocked at the time by the head of the femur, the

pressure of which has caused it. It is not until dislocation has taken place that the matter can pass into the pelvis, and then it does so by regurgitating into the cavity of the joint through the capsule which has been ruptured by, or prior to, the dislocation. Once within the pelvic cavity pus may pass in various directions. As pointed out in the chapter on the anatomy of this region, the destination of the pus is determined by the position of the perforation. It is sufficient here to say that pus may pass into the rectum, producing purulent stools, or accumulate around it, producing tenesmus; it may burst into the bladder and appear in the urine, or pass upon it and cause retention; it may ascend and point in the groin, or, rising still higher, open into the colon; or it may pass backwards and escape again from the pelvis through the sciatic notch. Sir Astley Cooper mentions a case in which the vagina was perforated. As to perforation of the rectum, an interesting specimen of this is to be found in the museum of the Royal College of Surgeons. (a) In this case the head and part of the neck of the femur have been destroyed. The acetabulum is much wasted, and contains two fistulous openings in its floor. One of these openings, extending obliquely backwards, communicates with the rectum by an orifice much larger than that in the acetabulum. The catalogue states that the rectal aperture is one-third of an inch in diameter, and is situated two-thirds of an inch above the anus. "The patient was a boy fourteen years old. The disease of the hip-joint was of long standing, and air used to pass with a quantity of foetid, thin discharge from a fistulous opening at the back of the thigh" (Catalogue). In St. Thomas's Hospital Museum is another specimen (b) showing perforation of the rectum. Here the bowel has become adherent to the pelvic wall opposite the aperture in the acetabulum.

Sympathetic Abscess.—It appears to be possible for an abscess to form upon the inner side of the pelvic wall at the same time as, but without connection with, that within the joint. Possibly this may simply be the result of irritation, or it may be caused by the passage of septic matter through lymphatic channels. Of abscesses of this kind there is an example in the museum of Guy's Hospital. (c)

Clinical Records.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

Case of Acute General Tuberculosis.

Under the care of Dr. C. E. ARMAND SEMPLE.

J. H., *et.* 4½ years, admitted Nov. 29th, 1882.

History.—Was healthy until eighteen months ago, when he had a scarlatinal rash (but no definite fever). He had measles three months ago, and was getting well over this, when some water was thrown over him. After this he had diarrhoea and cough. Has now had the cough two months, and has been getting thinner. There are six other children—healthy. Both father and mother suffer from chest affections. No history of phthisis in family.

On admission.—Pale and thin; tongue red in centre, white at back and edges. Pulse irregular; chest contracted laterally. No marked dulness over front of chest, but rhonchus all over. *Behind.*—Suprascapular regions somewhat dull, with loose crepitation; rhonchus and harsh breathing over rest of both lungs; coughs slightly. Abdomen enlarged; spleen felt below margin of ribs. Urine contains lithates; no albumen; no sugar.

R. *Misturæ olei morrhuæ*, ʒj.,

Vini ferri, ʒj. t.d.s.

Dec. 3rd.—R. *Misturæ ammoniæ cum ipecacuanhâ*, ʒss. 4tis horis. Milk and beef-tea diet. Chest poulticed.

(a) Preps. 934 and 935.

(b) Prep. D. 35.

(c) Prep. 1317^o.

6th.—Tongue dry, furred, and tremulous. Sordes on lips. Right arm rigid. Not any increase of cough.

7th.—Seems dull and heavy. Has a tendency to lie with all the limbs flexed. Makes no noise when moved, and does not answer when spoken to. Right arm markedly colder than the left, and there is much less power of resistance on this side, the arm falling helplessly on being raised; less resisting power also in right leg than in left. Hardly any sign of plantar reflex. It needs a decided prick with a pin to cause right leg to be drawn up, and the act is performed very feebly. No marked dulness over front of chest or in axilla, but harsh breathing all over, with rhonchus and coarse crepitation. Breathing somewhat tubular under right clavicle. *Behind.*—Flattening of percussion note in suprascapular regions. Rhonchus and crepitation at both bases. Liver extends about two fingers' breadth below margin of ribs. Edge of spleen felt below ribs. Patient showed signs of discomfort for the first time while spleen was being handled. Cannot sit up without support, and struggles to regain the recumbent posture. Ribs markedly beaded, and chest contracted laterally. Heart's action irregular. No bruit.

8th.—Last night and this morning difficulty of swallowing. Breathing somewhat laboured; lips dry; sordes on tongue and gums; pulse irregular; face flushed; skin over abdomen inelastic. No *tâche cerebrale*; no tenderness. Plantar reflex more marked. Eyes examined with ophthalmoscope. Discs swollen and hazy. No hæmorrhages.

9th.—In same condition. Fauces congested.

10th.—Pulse rather more irregular—full and strong; sighs a little. Plantar reflexes well marked. Slight cough at times.

11th.—At midnight breathing became laboured. Hands clenched. Cannot swallow since 4 a.m. Inspiration now difficult, shoulders being drawn back, and arms working convulsively. Right arm more affected than left; wrist flexed, and thumb turned in, but both can be extended with ease. Right lower limb extended throughout (toes pointed) with considerable rigidity. No plantar reflex. Died in the afternoon.

Autopsy.—On removing skull-cap, very little fluid found under dura mater. Surface of brain on both sides of median longitudinal fissure studded with tubercle. On the left hemisphere, close to the fissure, was a small collection of pus, under the arachnoid, in the pia mater, corresponding roughly in position to the back part of the superior or first frontal convolution. On removing this, the brain beneath, over an area of about one inch long and half an inch wide, and somewhat oval in shape, was found to be soft and of a greyish-red colour. After the removal of a slice of brain substance the following appearances were noted:—At several points patches were found at the bottom of the sulci, yellow in colour, and of a firm consistency. These patches were irregular in shape, the largest being half an inch long, and about two lines wide, and each was perforated by a vessel (the largest by two vessels), which appeared to be occluded. Around the yellow patches the grey matter was reddish, apparently from infiltrated blood. On making sections, it was found that these patches were continuous along the course of the vessels. The appearance of the patches suggested that tubercular growth round the vessels had taken place to an unusually large extent, so as to form considerable masses, which, nevertheless, could clearly be proved to have started from the vessels as their centre. The anterior part of the white matter in the centrum ovale was soft, but the softening did not appear to extend to the large ganglia. Tubercle was found in the vessels on microscopical examination.

Lungs.—No adhesions of pleura. Surfaces studded with tubercle, which also dotted the surface of the pleura. No other definite changes in the lungs. Bronchial glands large and cheesy.

Heart.—Normal throughout.

Liver.—Also studded with tubercle.

Spleen.—Very thickly covered with tubercle.

Kidneys.—Appeared to be healthy.

Nothing abnormal noted as regards intestinal tract.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, FEB. 9TH.

ANDREW CLARK, M.D., F.R.C.P., President, in the Chair.

Mr. SHUTER on

SUB-PERIOSTEAL AMPUTATION AT THE HIP-JOINT.

(Illustrated by Cases.)

On Oct. 16th, 1881, I held a consultation with Dr. Samuel West and Mr. Rose on a patient, set. 18, in whom I diagnosed acute necrosis, without suppuration, in the lower end of the left femur. This had led to septicæmia and secondary inflammation of the left hip-joint. Although my diagnosis was not supported, we were agreed that nothing but amputation at the hip-joint would save the boy's life. The next day the following operation was performed:—A circular amputation through the junction of the middle and upper third was done, followed by a longitudinal incision on the outer side of the femur down to the bone, the periosteum stripped off, and left in the flaps, and the whole of the bone enucleated. The patient made a good and rapid recovery. A little more than two months after the operation, he had a movable stump, and within six months of the operation he was wearing an artificial limb, on which he could get about very satisfactorily, and continued to do so until a few weeks ago, when I made him discontinue the use of it in order to get a sinus to heal. In 1859, Prof. Ollier, of Lyons, after performing many experiments on the lower animals, devised sub-periosteal operations on the human subject, with the view of getting bony supports to flaps cut for disarticulations. Among his suggestions was an operation similar to the one I performed on the hip-joint. My case, however, is the first successful sub-periosteal amputation at the hip-joint which has been attended with the formation of bone in the stump, and in which the patient has been able to wear an artificial limb satisfactorily.

Mr. BRYANT declared that he did not think he had ever seen a better stump than that possessed by Mr. Shuter's patient, but he was disposed to dissent from the supposition that it had a bony core of any amount. The periosteum itself afforded a good firm attachment for the muscles. He regarded the operation as first cousin to that devised by Mr. Furneaux Jordan, although this surgeon did not insist on preservation of the periosteum, to remove which, moreover, would not always be so easy as it was found to be in Mr. Shuter's case. The latter was a typical subject for the operation which had been performed, but in a fair proportion of cases in which amputation at the hip was found necessary it could not apply on account of the difficulty experienced in peeling off and preserving the periosteal covering. In those instances where the operation could be resorted to, however, it should certainly be preferred.

Mr. CROFT considered the case to offer an admirable illustration of sub-periosteal excision of the femur, which had been described as impossible of achievement. He would ask how Mr. Shuter had succeeded in denuding the great trochanter, for at the age of his patient this process would be almost completely ossified to the top of the femur, and consequently sacrificed. Did this happen, or was any difficulty experienced in removal of the attached muscles? He thought it right to leave a periosteal support for muscles when possible, but regarded the occurrence of such cases as being rare. He believed there was bone present in the stump, but its amount was uncertain. He congratulated Mr. Shuter on the admirable result of his operation.

Mr. BARKER testified to the excellent success of the operation, which, he explained, was similar to one he had

performed in February, 1881, and had recently published an account of. In this case, the patient was also provided with a good and serviceable stump, in which the same kind of hard core was present as in Mr. Shuter's case, the sub-periosteal method having been pursued in performing the operation.

Mr. CRIPPS did not think that any new bone had formed in the stump left after Mr. Shuter's operation, but that whatever seemed to have this appearance was simply necrosed bone. Both Mr. Shuter's and Mr. Jordan's operations occupied much longer time to execute than the old rapid transfexion method; and the danger of hæmorrhage, in dealing with which Mr. Jordan claimed advantages for his mode of proceeding, could now be removed by the employment of Mr. Davy's rectal lever. Under all the circumstances he doubted whether the new operation proposed by Mr. Shuter could be considered as an improvement.

Mr. PICK observed that the great advantage gained as the result of Mr. Shuter's operation was the readiness with which an artificial leg could be adapted to the stump. He instanced a case in his own practice six years previously, in which amputation had been called for on account of sarcoma, and which would have been admirably suited for the performance of Mr. Shuter's operation. Had this been resorted to, a much better result would have been secured; it was possible, however, that it might not have been feasible to perform it, the femur being a healthy bone with adherent periosteum. In such cases of amputation there was much difficulty in procuring fitting instrumental aid to locomotion, and consequently it was a great advantage to Mr. Shuter's patient to be able with his improved stump to walk with comparative facility.

Mr. HOWARD MARSH suggested the appointment of a committee to investigate the nature of the stump in Mr. Shuter's patient, and the characteristics of locomotion shown by him. He doubted whether there was any power to advance the limb by direct muscular effort. Mr. Cripps had raised an important question as to the superiority of Mr. Jordan's operation. The danger of hæmorrhage attending operation by the old method had been overcome since the introduction of the rectal lever by Mr. Davy, and he had himself witnessed the efficiency of the instrument on several occasions. Consequently, it would have to be considered whether on other grounds the newer mode of proceeding possessed advantages to encourage its employment. Having twice operated after Mr. Jordan's method he was able to testify to its tedious nature, and was inclined to regard the older and more expeditious plan as preferable.

Mr. BUTLIN pointed out the necessity for deciding how far preservation of the periosteum helped to secure a more useful stump, inasmuch as under the older method of proceeding sub-periosteal operation was impossible. He thought there was bone present in the stump of the limb amputated by Mr. Shuter. This stump was a much better one than was usually seen after such operations; and as Mr. Barker had added another successful instance to the same effect, the usefulness of the improved operation was unquestionable.

Mr. DAVY, while agreeing that no efficient result was obtained, as a rule, from the employment of apparatus to assist the locomotion of patients after amputation at the thigh, urged that, by Mr. Shuter's method, a focus was left for the action of the limb muscles. After nine years' experience, he found it very difficult to obtain any useful instrument for adoption to stumps left after amputation. On the subject of the rectal lever, he felt it his duty, as the responsible inventor of the instrument, to record a misfortune following its use, and occurring during an amputation on the right side in which he assisted by applying the lever to arrest bleeding. This was the thirtieth instance in which he had used the lever, and nothing untoward happened while the operation was in progress. In the evening, however, peritonitis set in, and death occurred on the next day. Post-mortem examination revealed a linear rent in the rectum [the specimen was exhibited] which had been produced by the lever, in consequence of its being caught in a fold of the gut at this point, the existence of a short meso-rectum explaining how it originated. Mr. Davy thought it highly important that the profession should have information as to the possibility of such a danger; and although his faith in the lever remained unshaken—it had been used in forty amputations (twenty on each side),

with recoveries in 65 per cent.—still it was desirable that surgeons should exercise the utmost possible caution in its employment.

Mr. M. BAKER had amputated at the hip in three cases, all of which recovered; but in none was there a stump at all equal to that possessed by Mr. Shuter's patient, nor would it be possible to enable either of them to walk as well as the latter by any artificial aid whatever. He considered, however, the good effect following the operation to be due to the length of flap employed, to which cause existence of bone was but secondary in importance. The site selected for amputation was the chief element of success.

Mr. H. MORRIS considered the appearance of the patient and his exhibition of locomotive power afforded the best proof of the excellent result secured by the operation, since there was evidence that the thigh was advanced in walking. He did not think the sub-periosteal method added either to the difficulty or tediousness of the operation; and cited two cases in which he had recently operated sub-periosteally, and with the result that the periosteum was easily removed, and good results were obtained. He was fully convinced of the advantages possessed by the method recommended in the paper.

Mr. C. LUCAS advocated the appointment of a committee to examine the case. He thought the bone present in the stump was exceedingly small in amount, and agreed with Mr. Baker respecting the advantage of long flaps.

Mr. SHUTER replied that he was of opinion there was bone in the stump of his patient, because in another case where death occurred three months after operation it was found, post-mortem, that a mass of bone was developed in the stump. He saw no reason to associate his operation with Mr. Jordan's, since the former originated in 1869 with Prof. Ollier—that is, long before Mr. Jordan's was devised. The periosteum had not been removed from the great trochanter in his own case, but it had been so in the fatal case referred to—that of a man 29 or 30 years old—in whom, consequently, it was not difficult to detach it. His operation was done October 17th, 1881. It need not be much longer in process than by Mr. Jordan's method; its advantages, however, were much greater so far as regarded the limb. After inquiry among instrument makers, who informed him that, though a good many new instruments were sent out, none ever came back to be repaired, he had come to the conclusion that even patients operated on by the long flap method are not able to make much use of artificial aids to progression.

The PRESIDENT nominated as a committee to investigate the case presented by Mr. Shuter the following members of the Society:—Messrs. Howard Marsh, Clement Lucas, and John Croft.

Mr. BENNETT MAY (Birmingham)

ON A SUCCESSFUL CASE OF NEPHRO-LITHOTOMY.

This case shows an advance on previous ones in point of size and weight of stone removed, this being 3 inches long and 473 grains in weight. The diagnosis rested on the prominent symptoms of pain, hæmaturia, and pus in urine. The patient is a coal-miner, æt. 34, and the history leaves no doubt that the stone must have been present and growing in the kidney for eighteen years. For the past year he has only been able to live in comfort by avoiding every exertion. The attacks of nephralgia were very severe, always in the left loin, and followed by hæmaturia for a day or two. Examination of the loin showed complete absence of swelling or hardness, or tenderness on palpation. Operation was done Oct. 20, 1882, the incision differing from an ordinary colotomy one in being higher up, so as to skirt the rib. Manipulation failed to make out a stone, but acupuncture detected it at once. The kidney substance was incised in a vertical direction until the wound appeared large enough to permit the extraction, which was accomplished entire by a sweeping action of the forefingers. Bleeding of a venous character was profuse, but controlled by pressure. The parenchyma of the kidney appeared healthy; there was no sign of pus or a sac. Urine came through wound on following day, and continued to flow till the 21st day, when it ceased entirely. The wound was soundly healed at the end of the fifth week. The urine has slowly returned to a nearly normal standard. For some time after operation it was strongly ammoniacal and turbid. It is now almost clear, acid, of sp. gr. 1020. He has tested his recovery by active exercise, &c. He feels perfectly well, free from pain, and fit for

ordinary work. The principal interest of the case surrounds the question of recovery. There is every indication of this being complete, and of the kidney having regained its functions as a healthy working organ. This is no doubt due to the fact, as pointed out in previous discussions at this society, that no destructive processes had been established in it.

(Patient shown with stone. Paper was preceded by an expression of indebtedness to the Society's published Reports, whence the writer had derived the information which enabled him to treat the case.)

Mr. HOWSE said he had performed this operation on the preceding Tuesday, and removed a small oxalate stone weighing 56 grains. The diagnosis of so small a stone was assisted by the history of the case:—Patient, a sailor, æt. 57, suffered six years ago from pain in the right side, which was very severe for twelve hours, and accompanied by vomiting. It ceased suddenly, and next day a quantity of sand was passed in the urine. These attacks occurred periodically each seven months until two years ago, when the pain grew continuous, and no sand was passed by the urine. On his entering Guy's Hospital the bladder of the patient was sounded without result, the pain being acute in right lumbar and iliac regions, and being described as "like needles in the kidney." There was tenderness behind, which was relieved by pressure, but pressure anteriorly created intense pain. The urine was of sp. gr. 1025, deposited no crystalline sediment, and but a small amount of mucus. The stone was felt by passing the finger to the anterior face of the kidney through a lumbar incision, but in order to remove it the lower part of the kidney was liberated, and the calculus freed by a finger aided by a forceps thrust into the wound made to admit its being reached. The temperature had once been 102° since the operation, but had receded to 99.4°, and the result was expected to be favourable. Mr. Howse instanced this case in support of his suggestion to explore the kidney from the front in all cases, as thus stones not discernible *a posteriori* would be revealed.

Mr. LUCAS observed that, in the major proportion of cases where large stones were found, the kidney structure was degenerated or destroyed by dilatation. If much degeneration, excision would be the better course to pursue. In Mr. May's case the diagnosis was unmistakable. Mr. Lucas supported Mr. Howse's suggestions.

Mr. BUTLIN commended Mr. May's modesty in speaking so unassumingly of his operation, the stone removed by him exceeding twice the united weights of the three largest stones previously exhibited to the Society. That it was good practice not to remove a diseased kidney unless absolutely necessary had been proved by the fact that his patient had experienced no return of disease in the organ, from which a large stone had been extracted. Mr. Butlin described at some length a case in proof of the doubtful diagnosis of stone in the kidney under some circumstances. In this particular case the symptoms appear to have been feigned with a view to trading on the feelings of religious enthusiasts.

Mr. H. MORRIS asked if Mr. Howse would advise the plan he had recommended in all cases. He feared to do so before diagnosis had been confirmed or attempted by exploring from behind and by puncture would be a dangerous proceeding. By supporting the loins, he thought the difficulty consequent on the non-resisting surface in front of the kidney would be removed. Mr. Howse's suggestion, however, offered a means of more complete investigation when other methods failed, and would be serviceable in future operations. The benefit sometimes following puncture of the kidney might be due to fixation of the loose organ consequent on its contraction.

Mr. MAY explained that he had brought forward the case in order to show the power of the kidney to return to a quiescent condition after removal of even a very large calculus. It would have been impossible to reach the anterior face of the kidney in this case, owing to the depth at which it was. He had tried in vain to fix the kidney by support, as suggested by Mr. Morris.

On the motion of the PRESIDENT, the thanks of the Society were conveyed to Mr. May for his excellent paper.

Communications on new tests for albumen in urine were read by Dr. Favy, and Dr. Oliver, of Harrogate.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

TREATMENT OF TYPHOID FEVER.—The question of typhoid fever and its treatment is far from being exhausted; the subject is brought before every meeting of the Académie de Médecine. At the last *séance* M. Sée passed in review the different methods of treatment, but without eliciting anything new. However, he promised to continue the subject next week. According to him the curative methods might be divided into three classes—expectation, antiseptic methods, and anti-thermic methods. The official type of the expectant method comprised beef-tea, a lemonade of citric acid, a little wine and water, and enemas, with poultices upon the abdomen. He was a partisan of this mode of treatment, if treatment it may be called. The antiseptic method had for aim the destruction of the microbes with their spores. These microbes were undoubtedly the bacilli of Klebs, or those of Eberth, but they commenced in the intestinal glands, and rarely in the lungs. The bacilli reside at the bottom of the glands, and gradually the mesenteric ganglions and the lymphatics of the abdomen. Consequently it was difficult, if not impossible, to attack them in the intestine. After enumerating the different antiseptics and antipyretics, M. Sée pronounced himself in favour of quinine, which he considered more effective than cold baths or salicylic acid and its preparations. As to digitalis, veratrine, and phenic acid, he considered them dangerous, as was also the treatment of Brand, which consisted in immersion in cold water at the first symptoms of the malady. The Lyons doctors, who adopted this treatment more frequently, have seen pneumonia complicating the fever as a result of the refrigeration. Intestinal hæmorrhage was also not rarely observed. The Lyons doctors, although they gave a bath at 73° or 75° Fahrenheit every two hours, confessed that the results were not favourable to the treatment. M. Moutard Martin thought that the principal aim in the treatment should be to prevent auto-infection, and that end might be best attained by repeated purging with saline purgatives and enemas. As to antiseptic agents, he accepted them only on the condition that they were not toxic, and he considered that sulphate of quinine at the dose of forty or sixty grains, if absorbed, was toxic. He rejected, for the same reason, phenic acid, as in small doses it was useless, and in large ones it was dangerous. He agreed with M. Sée that the best way was to treat symptoms.

HYPODERMIC INJECTIONS OF ETHER IN CASES OF IMMINENT DEATH FROM HÆMORRHAGE.—M. Georges Hayen, of the St. Antoine Hospital, read a paper on the "Value of Hypodermic Injections of Ether in Cases of Imminent Death from Hæmorrhage." In his report he said that transfusion of blood, although frequently practised abroad, had but few partisans in France; yet if medical men would only give it a fair trial he was sure their verdict would be in favour of it. He could not help thinking that the criticism made upon the operation was much exaggerated. His colleague, M. Verneuil, gave it as his opinion that transfusion of blood was a difficult, dangerous, useless operation; that the blood, acting only as a stimulant, could be easily replaced by subcutaneous injections of ether. Emanating from such a high authority, this assertion gave him food for reflection. Could it be true that transfusion could be replaced by an operation as easy and relatively as inoffensive as the injection into the cellular tissue of a few drops of ether? Immediately he determined to put the merits of the proposition of M. Verneuil

to the test, and for that purpose he experimented on a lot of ordinary street dogs, and the result was completely in favour of transfusion. He bled until convulsions commenced, indicating the approach of death, and although he injected ether four times, the dog died. In an exactly similar case he performed transfusion, and the dog recovered. Other experiments continued to prove the uselessness of ether, and, on the contrary, the exceeding great value of transfusion, which in nearly every case operated complete resurrection. As to the danger of the operation, it was greatly exaggerated, but he insisted on the absolute necessity of employing non-defibrinated blood. On the contrary, he considered that blood injected without its fibrine was not safe, and did not give good results.

IODINE BLISTERS IN TABES MËSENTERICA.—In *tabes mesenterica*, Dr. Bouchut, of the Children's Hospital, recommends the application of blisters, or the tincture of iodine, upon the abdomen, and if ascites were present tapping should be employed without hesitation. The *régime* to be followed should be very severe—beef-tea, eggs, raw milk, and claret. If diarrhoea be present, enemas of borax, one drachm each time, should be given, and three or four teaspoonfuls of glycerine in the day, by the mouth. Bismuth, or phosphate of lime, would be very useful. Your correspondent tried this treatment in an apparently hopeless case, and a rapid recovery ensued. The disease was far advanced, and the child was abandoned by its ordinary medical attendant.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 40, Bombay 28, Madras 42, Paris 26, Geneva 20, Brussels 27, Amsterdam 26, Rotterdam 28, The Hague 28, Copenhagen 29, Stockholm 27, Christiania 17, St. Petersburg 43, Berlin 21, Hamburg 26, Dresden 23, Breslau 30, Munich 25, Vienna 32, Prague 35, Buda-Pesth 29, Trieste 39, Venice 38, New York 28, Brooklyn 19, Philadelphia 22, Baltimore 34.

The annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Portsmouth 17, Bristol, Brighton 18, Edinburgh, Cardiff, Derby, Nottingham 19, Leicester Bradford 20, London Salford, 21, Norwich 22, Huddersfield, Wolverhampton, Newcastle-on-Tyne 23, Plymouth 23, Birkenhead, Birmingham, Bolton 24, Preston, Hull, Leeds, Sheffield 25, Halifax, Glasgow, Oldham, Liverpool 30, Manchester 32, Dublin, Blackburn 34, Sunderland 35.

FROM diseases of the zymotic class in the large towns last week the highest annual death-rates per 1,000 were— from scarlet fever, 1·7 in Sunderland, and 2·3 in Leeds; from whooping-cough, 2·7 in Wolverhampton, and 3·3 in Hull; and from fever, 1·1 in Preston and in Salford, 2·1 in Liverpool, and 4·3 in Blackburn. Six fatal cases of measles were recorded in the Birmingham Union Workhouse. The 43 deaths from diphtheria included 20 in London, 10 in Glasgow, 2 in Edinburgh, 2 in Birmingham, 2 in Sheffield, and 3 in Nottingham. Small-pox caused 5 deaths in London, 2 in Newcastle-upon-Tyne, and one in Liverpool.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, FEBRUARY 14, 1883.

STIMULANTS AND NARCOTICS.

An inquest was held by Sir John Humphreys at Poplar on the 6th inst. in a case of a kind with which we are now only too familiar. It was that of a surgeon, who died somewhat suddenly on board the ship in which he had returned from New Zealand, and whose death was traced to an overdose of chloroform. An examination of the medicine case of the ship, which had been well stocked at the beginning of the voyage, showed that every drug of a narcotic and sedative nature had been used up, although there had been no sickness on board calling for their employment. It was, therefore, evident that the surgeon who was in charge of the chest had himself consumed them; and had at last rashly swallowed what had proved a fatal amount of chloroform. Every now and again we hear of a similar case, in which a medical man, an artist, or a cultivated woman has perished from an excessive dose of some drug to the use of which they had been addicted; whilst their nearest friends had not, perhaps, suspected them of any such vicious indulgence. Such cases excite a momentary surprise and a passing comment; but scattered as they are amongst the multitudinous events and moving incidents of modern life, their true significance is not appreciated. It would, indeed, be impossible to form any estimate of their number; for in the public records they are not distinguished from deaths by misadventure and accident. And yet a study of a few of these cases, especially in

connection with general medical experience, may well excite the apprehension that they betoken a very serious and wide-spread social evil. We congratulate ourselves on the diminution of intemperance amongst our cultivated classes, and look back with a sense of lofty superiority on the drinking habits of our grandfathers; but it would shake our self-complacency should it be shown that, while open drunkenness has diminished, secret indulgence in narcotics and sedatives has enormously increased. And yet there are good grounds for suspecting that this is so. The cases in which drugs of these classes are directly fatal must hold a very small proportion to those in which they are taken habitually without any injurious effects that are recognised as being due to their action, and yet these fatal cases are of sadly frequent occurrence. Then the manufacture of drugs of these classes, and of patent medicines, into the composition of which they enter, goes on increasing at an alarming rate, and it may be shown that this is so as regards certain drugs, the medical use of which has, owing to changes in practice, greatly diminished. As civilisation has advanced crimes of open violence have been in great measure replaced by crimes of subtlety and fraud, and it may be that a similar transformation has taken place in respect to the manifestations of vice—those of a private and comparatively inoffensive character having supplanted those of a coarser, more public, and brutal type. It may be that, while drunkenness, which is open and immediately compromising, has diminished, narcotism, which is hidden and unsuspected, but not less insidious and dangerous in its consequences, has increased. However this may be, it is clear that we are in need of trustworthy information as to the prevalence of indulgence in narcotic and sedative drugs in different classes of the community. A succession of startling deaths from chloral and morphia may ultimately lead to the appointment of a Royal Commission to inquire into the subject, when we shall certainly have some extraordinary revelations; and meanwhile much good might be done by an instruction from the Home Office to all coroners throughout the country to distinguish in their returns all cases of death in which narcotic or sedative drugs have played a part. In this way we shall obtain some slight indication of the prevalence of practices that can only lead to social disaster, and shall have public attention intelligently directed to a subject which is of great and growing importance.

THE CASE STATED AGAINST THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES BY THE ATTENDING PHYSICIAN.—No. VIII.

We may fairly epitomise the Reports of Town Clerks and Medical Officers of Health, which were collected by the English Local Government Board, by saying that they all express opinions, more or less emphatic, that the working of the compulsory notification law has proved satisfactory and beneficial in their districts, but almost all omit to sustain this opinion by reliable statistics of death-rate.

Two only out of the twenty-five Reports, those from

Huddersfield and Greenock, are of value as furnishing this information, and we think it fair to publish a few paragraphs, although that from Huddersfield goes to controvert our own case.

The Medical Officer of Health for the borough writes as follows:—

“As these Acts are upon their trial, it may, perhaps, be worth while to compare our death-rates from diseases since the Act came into force with those before. From small-pox, during the eight years '69 to '76, our average death-rate was 139 per million. During the five years from '77 to '81, 4 per million. From scarlet fever, for the eight years before our Act came into operation, 928. During the five years that our Act has been in operation 606 per million. From 'fever,' chiefly typhoid, eight before the Act, 646 per million. Five years past, 368. Percentage decrease in zymotic death-rate for the latter over the former period: Small-pox, 97; measles, 16; scarlet fever, 35; fever, 43; diarrhoea, 37.”

This is undoubtedly a forcible statement; but to arrive at a just conclusion the figures must be discounted by deducting from the recorded decrease the normal decrease which would have occurred if compulsory notification had never existed. In every town in England in which any attention has been given to sanitation this decrease in mortality has been substantial; it has arisen from the improvement of sewerage and drainage—the clearing away of old tenements, the formation of open spaces, the establishment of a system of prompt scavenging, and the building of labourers' dwellings. These measures are all apart from notification, and the benefit derived from them must not be placed to the credit of that system; indeed, the Huddersfield Medical Officer of Health admits that “general sanitary measures have been chiefly the cause of the improvement” quoted above. He makes a further statement which goes to show that compulsory notification has little to say to the change for the better. He says that the death-rate from measles in his borough has gone down from 329 per million of inhabitants to 278; but he adds: “We have not asked for any notice in cases of measles; it has often been voluntarily tendered, and under very special circumstances we have taken cases into hospital; usually, however, we have interfered very little with the natural course of the epidemic.” Here is, then, an unnotified disease constantly present in the same town with notified diseases, and yet we find the change for the better just as apparent where notification is ignored as in the case of other diseases to the detection of which notification was applied.

Side by side with Huddersfield—a town in which the physician is compelled to notify—we place, for comparison, Greenock, the only town in which notification is thrown on the householder, the physician being left perfectly free. The Medical Officer of Health of this town says that he would like to have the doctors pressed into his service, but compulsion does not exist, and therefore, out of 4,423 reports received by him, only 106 came from medical practitioners, and these were purely voluntarily. Nevertheless, householder notification seems to have proved very efficacious in this town. The Medical Officer of Health says:—

It may now be asked what have been the real results following upon the system of notification in regard to death and disease? Whereas for the quinquennial periods

'61-65, '66-70, '71-75, the average death-rate was respectively 33.6, 29, and 30.6, it fell in the five years '76-80 to 23.8; the rate for 1881 being 22.05, which is the lowest on record since the introduction of registration in 1855. Again, while in the five years 1871-75 the annual average of deaths from small-pox was 55.20, from measles 50, from scarlet fever 93.40, from typhus 29.80, from enteric fever 36, and from whooping-cough 69; in the five years ending 1880 the annual average of deaths from these respective diseases was 20, 13, 28.20, 12.20, 19.20, and 45.60. Further, while in the 22 years '56-76 the average annual percentage of zymotic deaths to the total deaths was in Greenock 27.05, and was exceeded only and very slightly by that of Dundee (the highest in Scotland), the five years 1877-81 it was only 13.95, so that of Greenock was actually the lowest. Taking scarlet fever alone, the improvement, however, in reference to this disease will perhaps be better appreciated when it is stated that in 1859 the number of deaths arising from it was 266; in 1864, 148; in 1869, 180; in 1871, 106; in 1873, 131; in 1874, 102; in 1876, 109; whereas in 1881, with an epidemic giving 526 cases, there was a mortality of 37 only, which is equal to 5.1 per cent. of those affected.

We feel justified in asking, with these facts before us, why there is any necessity for placing the medical profession under compulsion? and what becomes of the statement by Dr. Littlejohn, of Edinburgh, that “householder notification in the case of the very poor becomes a farce,” and that “no scheme yet suggested gets rid of these difficulties except the one . . . which throws the responsibility on the medical attendant.”

We have thus endeavoured to show that the evidence laid before the Select Committee fails entirely to prove the case in favour of compulsory notification by the physician. Not only is this so, but there is good reason to believe that that form of notification has actually increased zymotic disease in some of the towns to which we have referred.

Direct evidence on this point is derivable only from a comparison of mortality of the selected towns before and after the introduction of compulsory notification, and this information is at the disposal of the Medical Officers of Health of those towns, and of no one else. These officers have been repeatedly challenged to prove the benefits of physician-notification by these death-rate statistics, but have omitted or declined to do so, and we, therefore, feel ourselves justified in assuming that an appeal to such evidence would not serve their case, and that the mortality statistics are, therefore, carefully ignored. We have also again to remind our readers that, wherever the zymotic death-rate of any town has become less after the introduction of compulsory notification, it is by no means to be assumed that the improvement is the effect of the new system. A review of the working of the notification system from this point of view was communicated by Dr. Carter, of Liverpool, to the Public Health Section of the British Medical Association at its last meeting at Worcester, and the author has put the actual facts in such a convincing form that we cannot pursue our argument in a better way than by quoting them:—

Dr. Carter takes for examples Bolton and Huddersfield, the first of which has had absolute, and the second contingent, compulsion longer than any other towns in England, and both of which have been cited by the admirers of this system as conspicuous examples of its advantage.

The details of the plan adopted by the advocates of compulsory notification in arguing their case is such as

ought to excite suspicion in the mind of every reasonable man (not to say every statist). One would think that, so far as fairness could be obtained at all by a method in itself radically defective, it would have been by a comparison of the sanitary condition of a town during an equal period before and after compulsory powers were obtained. But Bolton compares ten years before with only five years after; Huddersfield, eight years before with five years after; while Warrington carries the absurdity to its furthest limits by comparing nineteen years before with two years after. It should be specially noted that even the shortest of these periods carries us back to a date some years antecedent to the Public Health Act of 1872, before which, as everyone who has considered this question at all knows, decade after decade passed without the slightest sanitary progress throughout the country.

Yet, accepting what must be considered as the most favourable statement possible for these towns, that which they and others specially put forward as proving their case, what do we find? Why, that Liverpool, which for many reasons is more liable to the inroad and spread of infectious disease than any other town in the kingdom, has progressed during those very years nearly half as fast again without any compulsory Act, as Bolton has with one. If you will examine the figures on the table you

Average Annual Mortality per 1,000 Inhabitants.

	BOLTON.		LIVERPOOL.	
	1867-76. (10 years before the Act.)	1877-81.	1867-76.	1871-81.
Small-pox.....	0.12	0.004	0.54	0.12
Scarlet fever.....	1.10	0.82	1.45	1.04
Fevers { typhus } typhoid } simple }	0.57	0.33	1.15	0.57
	1.79	1.154	3.14	1.73
Populations.....	94,000	105,000	493,000	535,000

will see that the average annual mortality per 1,000 from small-pox, scarlet, typhus, typhoid, and simple fevers, fell in Bolton, from 1.79 in the first period of ten years, to 1.54 during the second period of five years; whereas in Liverpool, during the same periods, from the same diseases, it fell from 3.14 to 1.73. (I must incidentally introduce a slight correction here. Bolton's figures, although said to be carried through 1891, only went up to October of that year. In November, small-pox made its appearance, and, in spite of this Act for strangling it at its very birth, grew into an alarming epidemic. If the last two months of the year had been included, it would have made Bolton's position more unfavourable than is here represented). But, leaving aside this, several potent circumstances which tended to make the death-rate of Bolton appear less than it really was. If Bolton had progressed as fast as Liverpool, her mortality from these diseases should have been 98 per 1,000 instead of 1,154. Yet the medical officer of health, to quote his own words, considers that "the above evidence illustrates in a striking manner the beneficial effect of the compulsory clause, and fully justifies all that has been said in its favour." And if, instead of comparing Bolton's progress in these diseases with that of Liverpool, we compare it with that of the country generally, we find a similar result, viz.: Bolton, with her compulsory notification, lagging considerably behind the country generally without it. The average annual mortality per 1,000 for England from these diseases during the earlier period was 1.78. Bolton and the country then started on the race for improvement from almost exactly the same level. Yet, during the succeeding four years (the only ones for which the Registrar-General's returns admit of a comparison), the country generally had progressed so much the faster, that its average annual mortality from them had sunk to 1,047, instead of only to 1,154.

In the same way, without going into details, it can be

shown that, if Liverpool had only progressed as fast as Huddersfield in these test diseases, her mortality from them during the latter period should have been 1.8 per 1,000, instead of, what as a matter of fact it is, 1.73. Where, then, is the proof alleged by Mr. Hastings and others to be afforded by these figures of the benefits of compulsory notification?

(To be continued.)

SUB-PERIOSTEAL OPERATIONS.

THE question of sub-periosteal operations has, since the researches of Ollier were communicated to the profession, assumed a gradually increasing importance in surgery, and is now one of those subjects on which the majority of operators have fixed a degree of interest and attention compatible with the results to be obtained. At the Clinical Society on Friday evening there was shown a patient whose left leg had been amputated at the thigh in October last, and who now possesses a stump which was correctly described by several speakers as by far the most successful one they had ever seen. The operation in this case had been by the sub-periosteal method; that is, the femur had been excised after first removing the periosteum, and the latter was left in the limb to serve as a possible source of new bone. As to whether there was or was not a bony core present in the stump there was some diversity of opinion among members of the Society on Friday; but complete unanimity was shown respecting the superior powers of progression possessed by the patient, while it was satisfactorily demonstrated by the latter himself that he was able to advance the limb by muscular efforts, and not by a species of twisting of the stump observed in most instances of the kind. As an indication of the practical value of the improved operation, nothing more satisfactory could have been advanced, and Mr. Shuter is fairly entitled to the congratulations expressed regarding it by the surgeons assembled to hear his description of it.

Whether the reasons adduced in favour of an adherence to the older method of circular operation should be allowed to influence the future choice of surgeons who are called upon to amputate a limb, must depend ultimately on the verdict with which the newer method is received. If we judge from the effect produced in a single instance, it will be tantamount to exclaiming "*ex uno disce omnes*," a conclusion scarcely justifiable in any circumstances where such serious considerations are in question. But even now testimony is to hand from Mr. Barker, of University College Hospital, which explicitly demonstrates the value of sub-periosteal amputations, a case recently recorded by him, and in which he had preserved the periosteum of an excised femur, being adduced in proof of the superior advantages possessed by the stump so treated. There is, according to Mr. Barker, an unmistakable bony core present in this instance; and it has been developed since the operation was performed, a result claimed by Mr. Shuter as, at any rate, in process of being secured in the case presented by him to the Clinical Society. There seemed to be a difference of opinion, however, among the surgeons who joined in the discussion, as to the true nature of this deposit, some asserting their belief in favour of, and others against, the supposition. It may, therefore, be well to recall a few authenticated

instances in which the re-formation of veritable bony tissue has actually been observed after excision of all or part of the femur, or of other bones of the lower limb; and for such instances we need refer no further back than to the Proceedings of the Surgical Section of the great International Congress of 1881. Among the papers read at this meeting, one by Dr. Lewis A. Sayre recorded the reproduction of an entire hip-joint after excision in a young girl, from examination of which by Dr. Heitzman it was seen that "not only was the bone reproduced very nearly in form, size, as well as length, of the opposite one, but also true articular cartilages had been newly formed, and the motions of the joint were quite free." In this instance, it is true, the specimen was not produced for the inspection of members of the Congress, but in subsequent discussion on it Mr. Bryant referred to a case in which new bone was formed to replace the "head, neck, trochanters, and two and a-half inches of the shaft of the femur" taken away, on account of necrosis following acute periosteal abscess. On the same occasion also Mr. C. Macnamara described the formation of a new tibia in a boy from whom he had removed the shaft of the pre-existing bone, the periosteum being definitely stated to have been left in this case—a detail of much importance now, but omitted by the other speakers at the Congress referred to. A still more interesting example of re-formation of bone was described also by Mr. Macnamara, in the case of another child from whom he removed the tibia. Here the periosteum was left likewise, but because the membrane was unhealthy and unequal to the task, no vestige of new bone appeared, and after six months the limb was "planted" with pieces of fresh periosteum and bone removed from a newly-amputated foot. The pieces were placed as nearly as possible in the situation the tibia should occupy, and at the time the paper was read—six weeks after—a narrow ridge of bone could be felt along the course of the osseous tissues thus transplanted. The further history of this remarkable case would prove highly interesting, and we venture to ask Mr. Macnamara to communicate it to the profession.

A very important point in connection with these operations is that of the condition of the periosteum involved. We have it sufficiently shown by Professor Ollier's exhaustive researches that regeneration of bone is absolutely impossible from periosteum after the age of thirty or thirty-five years; that is, that the healthy periosteum of young persons alone is competent to the reproduction of bony tissue. But M. Ollier also has proved that a previous irritation of the periosteal membrane, by whatever artificial means excited, is sufficient to ensure very different consequences, and the periosteum so excited is competent to perform the function naturally assumed by the membrane at an earlier age than adult life. In the words of the illustrious surgeon just quoted, "le périoste âgé reprenait ainsi les propriétés du périoste jeune."

It would be premature to insist on the possible advantages likely to follow from the general adoption of sub-periosteal methods of operation; but it is not too early to express satisfaction at the success which has attended such practical applications of M. Ollier's experimental results as have already been made in the field of surgery. It would

appear as though a number of unconscious adapters of his mode have already been imitating his proceedings, and in every case of which a record has appeared success greater than anticipated has been the result of the proceeding. It would be interesting at this point, if space permitted, to discuss the pathological reasons why these results obtain, for in the explanation afforded by them in the light shed upon their causation by M. Ollier's researches probably lies the justification of a widespread adoption of sub-periosteal methods; but for the moment we must defer the attempt. The fact, however, remains indisputable that by the adoption of a method of operation not generally recognised by surgeons, results not previously attainable are placed within the reach of every skilled operator; whether as a consequence of bony regeneration or of improved length of flap may, for the moment, be left an open question.

THE COMBINED EXAMINATION FOR IRELAND.

THE sub-committees appointed by the Irish Colleges of Physicians and Surgeons to negotiate a combination of the examinations of the Colleges for the grant of an Irish double diploma, presented last week to their respective Colleges the following resolutions agreed to by them:—

1. "That it is desirable that the King and Queen's Colleges of Physicians and Royal College of Surgeons in Ireland should combine, so as to give a complete Examination in Medicine, Surgery, and Midwifery."
2. "That candidates who pass the combined Examinations shall be entitled to receive the Licences of the Colleges in Medicine, Surgery, and Midwifery."
3. "That it is necessary, to meet the requirements of the case, that each College should reduce the fee charged for its respective Diploma by an equal proportion, so that the whole fee to be paid by each successful Candidate shall be £31 10s. for the Diplomas in Medicine, Surgery, and Midwifery."
4. "That the Colleges do bind themselves not to grant separate Diplomas, except to Candidates who already hold, in the case of the College of Physicians, Surgical Diplomas approved of by the College of Physicians; and in the case of the College of Surgeons, Medical Diplomas approved of by the College of Surgeons."
5. "That after payment of the expenses of the Professional Examination, the surplus remaining should be divided between the Colleges of Physicians and Surgeons in the following proportions, viz.:—Three-eighths to the College of Physicians, and five-eighths to the College of Surgeons."

We understand that the Council of the College of Surgeons has discussed all these propositions, and accepted all excepting the 4th. The College of Physicians has approved the first three, but has not yet discussed the others. The decisions thus come to are of the highest importance as indicating the laudable disposition of the Colleges to make great sacrifices for the sake of a *modus vivendi*. The reduction of the diploma fees from £42 to £31 10s. will involve an immediate loss of 25 per cent. of the total income of both Colleges, equivalent, in the case of the College of Surgeons, to about £1,500 a year. This most serious diminution of the Collegiate resources may be, to a certain extent, compensated for by a saving in the expense of examining, and, possibly, by an increase in the number of Licentiates arising from the attractive-

ness of a combined examination and a reduced fee, but we are not sanguine enough to anticipate that even the greater part or the loss to the Colleges will be so recouped.

The fourth resolution, which has been rejected by the Council of the College of Surgeons, would, in our opinion, have been suicidal.

That the College should drive from its doors all students who had not already received a qualification elsewhere would, we believe, have closed the doors of the institution in semi-bankruptcy in a few years. It would have at once thrown the student into the arms of the Royal Irish University, and it would, we think, be very unlikely that, being once enrolled as a matriculant or graduate of that institution, he would ever come back to seek the licences of either of the Colleges.

These negotiations will prove useful as *pourparlers* premonitory of the coming conjoint examination legislation, but we do not regard them as having any other value, because we have no belief in the possibility or efficiency of partial and voluntary combination of licensing bodies. The Scotch double diploma has been a money-making speculation simply because of its low curriculum and short period of study. It would have been almost equally successful if there had been no combinations of diploma, provided that the separate diplomas were offered on as easy terms. But the Irish Colleges do not propose to offer these attractions. They are not going to reduce their curriculum to two years, or to cut down their examinations to Scotch level, and we therefore do not for a moment believe that an abatement of £10 in the diploma fee will ever prevent Irish students from running to Glasgow and Edinburgh for handy qualifications to practise.

Conjoint examination under the Medical Act which, we trust, is coming, would be altogether different in effect. It will certainly reduce the central examination fee to £31 10s., but it will also put a stop to the exodus from Ireland to Scotland, and will thus increase the earnings of the Irish Central Board, so as to recoup the Colleges for their loss of income. Students will then have no inducement to go north of the Tweed, because they will save nothing in period of study nor stringency of examination by so doing, and we confidently believe that the result will be a great and lasting benefit to the Irish Colleges as well as to the profession and the public at large.

Notes on Current Topics.

Dr. Littlejohn's Opinion of his Profession.

THE Medical Officer of Health for Edinburgh has at last responded to the demands made by the Liverpool and Dublin physicians for a retraction and apology for his calumnious statement to the effect that the profession in these cities opposed compulsory notification with the sordid motive of saving their fees. He has addressed a long letter to every medical journal except the *Medical Press and Circular*, in which he feels it necessary to "frankly admit that" he "erred in referring to the medical profession protesting against loss of fees without then repeating the foundation for the statement." He does not attempt to justify the "allegation that the

medical profession of Liverpool or Dublin or any other city would be actuated by such motives, and" he regrets "exceedingly that any corporate body should have supposed" him "capable of charging the profession with opposition to a public movement on selfish grounds." He repeats his regret at "having done so in terms liable to misconception."

The amount of this apology is that Dr. Littlejohn is sorry for having slandered the profession without giving the foundation for his charges. But the "foundation" which he pleads makes his offence ten times worse. It seems that the basis of the assertion for which Dr. Littlejohn has been brought to his knees is a still more calumnious statement made in the *Glasgow Herald* by himself, as follows:—

"The bugbear, however, that is always urged is that notification necessarily implies removal of the patients to an hospital and the consequent loss of fees to the medical attendant. This was unblushingly pled with regard to Liverpool, and to Ireland generally, at the meetings lately held at Worcester and Nottingham."

Dr. Littlejohn continues:—

"The question remains, whether I was justified in stating that the loss of fees had been put forward at Worcester and Nottingham in the interest of Liverpool and Ireland as an argument against compulsory notification. On that point I can only say that this statement was founded on my own recollection of what I had heard said by Drs. Fitzpatrick and Whittle, of Liverpool, and Dr. Jacob, of Dublin. I cannot suppose that any of these gentlemen would dispute that this was one of the arguments adduced by them on the occasions referred to."

It is our deliberate opinion that a Medical Officer of Health who insults the body of his profession because his "own recollection" informs him—perfectly falsely—that certain statements were made by individuals, is entirely unfit to criticise the motives of any class of gentlemen. The Hon. Sec. of the Lancashire and Cheshire Branch of the British Medical Association has already, on behalf of Drs. Fitzpatrick and Whittle, publicly informed Dr. Littlejohn that no such statement was made at Worcester as he has imputed to them, and we, on the strength of our "own recollection," are able to contradict, in the most positive manner, the assertion that any such motive for objecting to compulsory notification was "unblushingly pled" at Nottingham by Dr. Jacob or anyone else.

Therefore Dr. Littlejohn's "own recollection" has proved an insidious informant, and he is deprived of the "foundation" for his calumny, which he has pleaded as his excuse.

Next time he feels himself moved to advocate compulsory notification, we trust he will either refrain from his present line of argument, or else try to sustain it by some more solid foundation than his "recollection."

Small-pox at the Cape.

THE Natal Government have decided to wait for thirty days after the last case of small-pox at Cape Town has been reported cured before removing the quarantine restrictions on ships from that port. During the three or four months when the epidemic was most severe, 2,000 deaths occurred out of a total population of 40,000, and of the whole number thus fatally infected, 38 per cent. were unvaccinated, while but 13 per cent. of vaccinated persons perished. This result comes with

appropriateness just now, when the Anti-vaccination League of this country are straining every effort afresh with a view to securing more freedom for the indulgence of their crotchets during the current year. To the authorities at the Cape the recent visitation will presumably teach a much-needed lesson in respect to their hygienic surroundings. These, never of the best, demand the most wholesale improvement immediately, and with the recollection of such terrible experiences as have just been gone through, it is probable the party of reform will, even at the expense of increased taxation, be successful in introducing measures designed to secure a greater degree of protection for the public health. If this occurs, even so great a loss as has been mentioned will not have been unproductive of benefit.

A Luminous Verdict.

THE native Mancunian has often been held up to general admiration as a far-seeing example of intelligence not less praiseworthy than the proverbial Scotchman; but unless some explanation is forthcoming to show that the jury who recently decided that an unqualified practitioner was "to blame for not telling the wife of the deceased that he was not a properly-qualified medical man" are not true representatives of Cottonopolist acuteness, then must we cease to look to Manchester for future guidance in the paths of "light and leading." "The deceased" referred to had been attended by a non-qualified person named Royle, and subsequently by Dr. Young. He died from natural cause, but, at the inquest held on the remains, it came out that "anybody might have been led, as the deceased had been, to believe in the medical qualifications of 'Dr. Royle,'" since this gentleman so paraded himself on his labels, prescriptions, &c. This conclusion appears perfectly justifiable, and seems to have influenced the jury in delivering the rider to a verdict of death from natural causes to which we have drawn attention. The simplicity which could conceive the possibility that a man living by fraud would voluntarily brand himself as an impostor even to the wife of a patient, is too admirable; and scarcely less astonishing is the apparent ignorance of the deputy coroner—Mr. Sydney Smelt—who presided at the inquest, and who complained of the supineness of the Medical Society of Manchester in dealing with the hosts of quacks in practice in the city. Mr. Smelt should put to himself the question, Who is to bear the considerable expense entailed in prosecuting such pretenders, and especially when, as so often happens, the magisterial favour is evidently more for than against unqualified practitioners? If the duty of protecting the public against the latter were undertaken, as in all justice it should be, at the expense of the State, then, and not till then, will the prospect of punishment prevent the wholesale mischief they are the cause of producing. At present but few such prosecutions are undertaken, because of the certainty that none but most glaring offenders can be successfully proceeded against, and because the private societies who undertake to bring charges of unqualified practice are unable to risk considerable sums of money on the chance of failure. At the present moment we know of at least a score of cases in which, for the sake of public safety and public decency

too, quacks should be proceeded against; but who is there, save the various medical defence associations, that can be appealed to to do the necessary work in connection with them? If Mr. Smelt and those who think with him will agitate for amendment in this direction, they will do far more than can ever result from querulous expression of such complaints as that just accredited to the deputy coroner of Manchester.

Quain's "Dictionary."—A Warning.

WE have been requested to explain that in the first issue of Dr. Quain's "Dictionary of Medicine" an error of a very important character has crept into the article on Phthisis by Dr. Theodore Williams. In this, p. 1181, it is stated that Dr. Murrell has found good effects to be produced by the drug picrotoxine in the night sweats of phthisical patients, and the dose recommended is 1.6th (*one-sixth*) of a grain. It is almost unnecessary to say this is a misprint for 1-60th of a grain; but the error is of so important a character that Dr. Quain is naturally most anxious to secure its being corrected in every copy of the admirable work he has so ably edited. In the re-issue of the book, necessitated by the unprecedentedly speedy sale of a large impression, the mistake is rectified; but earlier possessors of the "Dictionary" will do well to make the required alteration in their copies.

The Action of Rarefied Air.

DR. A. FRANKEL, of Berlin, read recently an interesting paper on the above subject before the Medical Society of that city. For some time past he, in conjunction with Herr Geppert, has been making investigations into the subject, some of the results of which he made public in the paper above mentioned, and of which the following is a very brief account:—Rarefied air is mainly of moment through the diminished supply of oxygen that necessarily accompanies it. The important effects of such a diminished supply have been observed in cases in which the circulation has been greatly disturbed, in hæmorrhages, and in the action of most active poisons, as at least the secondary effect of these is to lessen oxidation. It has long been known that when the supply of oxygen to the body is diminished, the organs become subject to a more or less pronounced degree of fatty degeneration. So long as this is limited to the non-use or storing up of such fat as was already in the system, or brought into the system in the food, the process is not difficult of comprehension. The question becomes a different one, however, when, under the influence of a diminished supply of oxygen, fat makes its appearance in localities in which it is not normally present. Such localities are the muscular structure of the heart, the glandular organs in excessive anæmia, in which, under certain circumstances, the muscular structure completely disappears. The author's efforts had been directed to the solution of this problem. He has found that in case of diminished supply of oxygen, brought about, it may be, in the most diverse ways—by suffocation, or by carbonic oxide (CO) poisoning—the urea, or urinary excretion of nitrogen, undergoes a considerable increase. From this it will appear that the diminished supply of oxygen causes an increased disintegration of structural albumen. The

nitrogenous components of the albumen are discharged from the system in the urine, and the non-nitrogenous remain in the form of fat. Recent experiments permit this fact to be proved in a manner to which exception cannot be taken. Dogs were enclosed in a ventilated pneumatic chamber the air of which was rendered gradually rarer by means of an air pump. After a time, very characteristic phenomena were observed (already described by P. Bert). If the rarefaction was brought about as slowly as possible, when the atmospheric pressure was reduced to one-third, the animals, without any dyspnoea worth naming, fall into a state of somnolence, in which they might remain for some seconds (*Sekundenlang*). In order to ascertain whether this condition, apparently due to want of oxygen in the brain, might not be really dependent on the mechanical action of the rarefied air on the circulation, the blood pressure was examined. This showed plainly no deviation from the normal. Neither could there be question of any accumulation of carbonic acid in the blood. It remained, then, that the above-named condition of somnolence was simply the effect of deficiency of oxygen. If the animals, before placing them in the pneumatic chamber, had been fed so carefully that the daily excretion of urea was always the same in amount, it invariably increased considerably on putting them into the chamber and rarefying the air, thus indisputably proving, as Dr. Fränkel claims, that the diminished supply of oxygen causes disintegration of structural albumen, with retention of the fatty constituents thereof within the system.

Laparotomy.

PROFESSOR BILLROTH performed the operation of laparotomy for removal of a uterine myoma a short time ago under circumstances that would have rendered the completion of the operation impossible in the hands of many surgeons. He himself acknowledges that the operation was one of the most difficult he had ever performed, and at its close congratulated himself and his assistants on the patient leaving the table alive.

The tumour was of enormous size, but this alone did not render its removal a matter of such difficulty. It was its adhesion to neighbouring structures that offered the gravest obstacles, and demanded the most scrupulous care. The tumour was adherent at numerous points, to the omentum, intestines, and pelvic contents. The ureters, which were distended to the thickness of the little finger, were actually imbedded in the tumour, and had to be literally dissected out. In the separation of the bladder adhesions, this organ was torn, and it was found necessary to remove the upper part of it, after which it was sewn up. A ligature was now placed on the portio vaginalis, and the tumour removed. It weighed 21 kilogrammes. After removal of the tumour, flat sutures (*Plattennähte*) were first applied, then deep sutures, and lastly a running superficial suture; a drainage-tube was inserted, and the ordinary iodoform dressing applied. The operation lasted three hours, and it was at its close that the congratulations came in. The day following the patient was as well as could be expected, but soon the quantity of urine excreted fell to one-half, and on the fifth day she died. The report says that the diminution in the quantity of urine

could only arise from rupture of the sutures that had been placed in the bladder wound, thus allowing escape of urine into the peritoneal cavity, or from septic pyelitis.

The autopsy was made on November 17th by Dr. Zeemann. There was no peritonitis of importance, and the bladder sutures were perfect, so that there was no escape of urine. The right kidney was much atrophied; the left, however, considerably dilated. There was also pleurisy of the right side.

Sustained Muscular Effort.

AN extraordinary instance of sustained muscular effort was afforded during the flooding of the Australian mine at Sydney in December last. The drift from one shaft having unexpectedly broken into another, a rapid inundation took place, so that in a few minutes the lower levels were flooded, and the water stood thirty feet in the shaft. Twenty-seven men in one part of the workings were unable to ascend the shaft, being caught in a drift where the water soon rose so high that only by clinging to the timbers could they keep their chins above it. One by one during the terrible sixty hours that elapsed before help came did the men drop off exhausted, but five of them succeeded in holding on during the whole of that time and were brought out alive. The bodies of the other twenty-two were found scattered about on the floor of the drift. Great indeed are the strength and tenacity inspired by desperation when they could enable five men to hang on by their hands with their bodies immersed in water for sixty hours.

Mercurial Glycerite.

THE absorption by the skin of any medicament incorporated with a fatty substance is very feeble, except for mercurial ointment. According to M. Vigier (*Gaz. Hebdomadaire de Med.*), any substance incorporated with glycerine, as iodide of potash, chlorhydrate of morphine, &c., is not absorbed. He considers that this property of glycerine is due to its not wetting the skin. Experiments on himself and his pupils have proven that the active substance thus incorporated never produces its constitutional effects. It is for this reason that he recommends glycerine instead of lard in mercurial preparations for scabies, pediculi corporis, &c., as they have an anti-parasitic effect without being absorbed. The following glycerite, notwithstanding the caustic nature of its principal ingredient, may be used without danger:—R Hydrarg. bichlorid., ζ ss; glycerine, ζ ij. M.

MR. W. J. EVELYN, of Wotton, Surrey, has contributed 1,000*l.* towards the building fund of a Hospital which it is proposed to erect in connection with (and in close proximity to) the Royal Kent Dispensary, at Greenwich.

SURGEON-GENERAL R. GILBORNE has been officially gazetted Principal Medical Officer at Aldershot.

THE trial of Mr. S. J. Noake, L.R.C.P.Ed., of Leeds, who, it will be remembered, was charged with the wilful murder of the manageress of a coffee-tavern, by illegal surgical interference during pregnancy, was tried at Leeds last week and acquitted.

The Originator of Cottage Hospitals.

A GRATIFYING proof of the esteem in which Mr. Albert Napper is held by the profession, and of the value of the movement which he was the first to set on foot, was evidenced on Saturday last in London, when at a meeting, under the presidency of Professor Erichsen, a testimonial was presented to that gentleman consisting of an address on vellum, signed by upwards of 150 members of the profession, a cheque for a handsome sum of money, and a magnificent silver salver, bearing the following inscription:—"Presented to Albert Napper, Esq., M.R.C.S. Eng., of Cranleigh, Surrey, by some of his professional brethren and friends of the Cottage Hospital Movement, in recognition of the services he has rendered to the profession and the public as the founder of the Cottage Hospital Movement, January, 1883." It is with sincere pleasure we chronicle this practical mark of esteem and approval of the work initiated by our *confrère*, and wish him many years' enjoyment of his well-earned repose.

ON Thursday last Dr. Tyndall laid before the Royal Society a series of thermometrical records made at a testing station near Haslemere, which go to show that, with atmospheric conditions sensibly alike, the waste of heat from the earth varies from day to day, a result due to the action of a body which escapes the sense of vision.

AT the annual meeting of the delegates and collectors of the London Hospital Saturday Fund, held on Thursday last, at Exeter Hall, Mr. S. Morley, M.P., presiding, the report stated that the collection in 1882 had amounted to £8,690, being £516 above that of 1881, and £2,056 above that of 1880.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE ROYAL MEDICAL SOCIETY, EDINBURGH.—The annual dinner of the Royal Medical Society of Edinburgh took place on the 6th inst. in the Waterloo Rooms. Dr. J. G. Soutar, Senior President, occupied the chair, and Dr. James Hewatson, the Second President, officiated as croupier. The company included the Right Hon. the Lord Provost, the President of the Royal College of Physicians (Dr. G. W. Balfour), Dr. John Smith, Dr. R. S. Marsden, Dr. Byrom Bramwell, Professor Annandale, Professor MacLagan, Dr. John Duncan, Professor Flint, Dr. Lockhart Gibson, &c. In responding for the toast of the Army, Surgeon A. F. Russell took occasion to say that their good opinion was of great importance at present to the medical officers in the army, as a determined effort had been made in certain quarters to discredit their department. The medical journals had shown how false the chief accusations in connection with the Egyptian campaign were, but he regretted that the contradiction did not obtain equal currency in other journals. He hoped that, as the result of the investigation now going on, the department would be placed on a better footing, not only for treating the sick in the hospital, but for attending to them on the battle-field.

DUMFRIES INFIRMARY MEETING.—A Quarterly Court of Governors of Dumfriesshire and Galloway Infirmary was convened for the 6th inst., at noon, but there was not a

quorum, and the business was consequently referred to the weekly committee. All that was done was to receive accounts and appoint an audit committee. The accounts showed the ordinary receipts to be £1,615 15s. 7½d., against £1,608 5s. 1½d. in the previous year, and the extraordinary receipts (*viz.*, legacies), £1,420, against £810. The ordinary expenditure amounted to £1,705 12s. 11½d., against £1,710 5s. 8½d., and the extraordinary expenditure (for furniture), against *nil* in the previous year.

EDINBURGH.—NEW TOWN DISPENSARY.—At the annual meeting in connection with this institution, held on the 9th inst., Dr. Balfour presiding, the report by Dr. Cadell, the medical officer, was submitted, and showed that during the past year he had treated 10,086 cases. The treasurer's report stated that the income from subscriptions and donations had amounted to £318, and that there was at present a balance on hand of £28.

DUNBLANE.—DEATH OF DR. P. GORDON STEWART.—In May, last year, Dr. Peter Gordon Stewart returned from the Cape after an absence of 32 years, to spend the remainder of his days in the quietude of the Cathedral City. His sudden death, from what is believed to have been fatty degeneration of the heart, was quite unexpected. Dr. Stewart, who was in his 62nd year, was the fifth son of the late Cornelius Stewart, who practised in Dunblane for upwards of half a century, and died at the advanced age of 81. He took his degree at the age of 18, and was first his father's assistant. He afterwards practised at Auchenarder, where he was highly appreciated and much respected, and at a later period emigrated to the Cape of Good Hope, and settled at Rindebosch, a few miles from Cape Town. He was elected one of the Government Medical Board of Supervision of the colony, and was recognised as the leading consulting physician in the colony.

GLASGOW PUBLIC DISPENSARY.—The annual meeting of the friends and supporters of the Glasgow Public Dispensary was held on the 5th inst., Dr. Marshal Lang presiding. In the report which was read by the secretary it was stated that the institution was started six years since on the "provident" principle, its work being conducted under certain medical departments, to which special attention had been given by each medical officer. A more generous public support being forthcoming, the medical officers were desirous, by means of lectures, &c., that facilities should be afforded to students of cultivating a more special knowledge of the diseases which came under observation, and of treating the patients at their homes when unable to come to the dispensary under the supervision of the medical officers. The cases treated during the past year included 553 for diseases of the throat; diseases of the ear, 579; kidney, and urinary diseases, 375; diseases of women and children, 399; beside other cases attended at the homes of patients. The debt due to the treasurer up to the present time is £106 17s. 8d. The Chairman, in moving the adoption of the report, said it was impossible to look back upon the six years during which the dispensary had been in existence without feeling that it had accomplished a great amount of good. It was one of the most unobtrusive, and at the same time one of the most benevolent, agencies in the city. There could be no doubt this was emphatically a good work. Indeed, it was so good that perhaps it suffered, if he might so speak, from its very goodness. It did not appeal to any of the specialities by which causes were sometimes recommended. It was no secret that the dispensary was hampered by the want of a sufficiency of instruments. They were indebted to the medical men for the use of whatever instruments were employed, and it would be a very great gain if there were instruments always

at hand for the purposes of the institution, and that might be said to belong to it. He ventured to express the hope that next report would be more encouraging than that of this year, that the area of the relief given would be extended, and that the acknowledgment from the community of the good work done would be more encouraging.

GLASGOW DEATH-RATE.—For the week ending with Saturday, the 3rd inst., the death-rate of Glasgow was 30 per 1,000, being the same as that of the previous week.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 3rd inst., fell from 93 to 81, and the death-rate was 18 per 1,000. Diseases of the chest accounted for 40 deaths, and zymotic causes for 6, of which 1 was due to fever, 2 to scarlatina, and 1 to measles, the intimations of these diseases for the week being 13, 41, and 9.

PERTH HOME FOR INCURABLES.—The annual meeting of those interested in the Home for Incurables, Perth, was held on the 5th inst., Mr. Alexander Macduff, of Bonhard, in the chair. The medical report was read by Dr. Stirling, from which it appeared that at 1st January, 1882, there were 16 inmates in the Home, and that there were admitted during the year 16 patients, making a total of 32. Of these 9 died, 2 were discharged relieved, 1 was found unsuitable, 1 was discharged for bad conduct, and 3 were discharged by request, making a total of 16 remaining in the home at 31st October, 1882. Of the 16 admitted during the year, 6 were males and 10 females. Five were admitted from the city, 2 from the country, and 9 direct from the infirmary.

Correspondence.

THE HOMŒOPATHIC PHARMACOPEIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—I don't know where you found the "nasty filth" you speak of in this week's number as described in the *Homœopathic Pharmacopœia*. Certainly not in any of the editions of the *British Homœopathic Pharmacopœia*, which is the only authoritative work of the kind in this country. In an appendix to the *American Homœopathic Pharmacopœia* lately published, there is mention made of some so-called "isopathic" remedies, which are morbid products, and may well be characterised as "nasty filth," but they are not admitted into the pharmacopœia, and no directions for their preparation are given. I do not see what business they have to be even mentioned in a homœopathic pharmacopœia, as they do not belong to homœopathy, and, as you say, are only prescribed by "crack-brained practitioners of medicine," which I trust those who employ medicines homœopathically are not generally considered to be. I have not heard of the suppression of the *American Homœopathic Pharmacopœia* on the ground of its thefts from the United States Dispensatories, as you state, on the authority of the *Philadelphia Medical Times*. Many of the medicines are, of course, the same in both the orthodox and the homœopathic pharmacopœias, but the mode of preparing them is generally different, so I do not well see how the authors of the *American Homœopathic Pharmacopœia* could have copied from their orthodox rivals. However, as time goes on, so many of our medicines and processes have been adopted by your school, that it is quite possible that a new work on homœopathic pharmacœutics may seem to be a plagiarism of parts of an older allopathic work, whereas, if inquiry were to be made, it might turn out that much of the older work was copied from an earlier homœopathic pharmacopœia.

This assimilation of the pharmacœutics of the two schools should be gratifying to all who look forward to the ultimate disappearance of heresy from medicine. You are welcome to believe that we are plagiarising your medicines and methods; we, of course, are as firmly convinced that it is your school that is adopting our methods and medicines, and an examination of some of the most recent works of your

school on *Materia Medica* and *Therapeutics*, such as those of Ringer, C. Phillips, and Bartholow, strengthens us in our conviction.

I am, yours, &c.,

London, 7th Feb., 1883. R. S. DUDGEON, M.D.

Obituary.

DR. GEORGE M. BEARD, OF NEW YORK.

AN American medical celebrity has just passed away. Dr. George M. Beard, of New York, died in that city on the 24th of January, at the age of 44. The cause of death was pneumonia of an asthenic type. Dr. Beard has been long well known as a copious and fluent writer on neurological subjects. In the early part of his career he paid special attention to electro-therapeutics; but, as time went on, he became more and more psychological, and his latest contributions have been on the "Physiology of Mind-Reading," the "Mental Condition of Guiteau," and kindred topics. Unhappily, Dr. Beard did not always exercise that caution and reserve which are essential as safeguards to explorers in that dim region where medical science borders on mystery, and consequently he committed himself to views and brought forward experiments which could not bear the critical scrutiny of his professional brethren. Thus it was that his demonstrations on hypnotism and thought-reading came to so abrupt and ignominious a termination at the meeting of the Medical Congress in London in 1881. It is well known that these demonstrations were declined by the Council of two sections of the Congress before which Dr. Beard had volunteered to exhibit them; and that Dr. Beard's trained subject was shown to be unworthy of credit. But notwithstanding the publicity given to these events, and the correspondence respecting them, which took place in several medical journals subsequently, a knowledge of them does not yet seem to have reached the United States, for the *New York Times*, in its obituary notice of Dr. Beard, refers to the success of his experiments in artificial trance at the International Medical Congress in London. Dr. Beard's writings are often exceedingly suggestive, and many of them have had a large general circulation.

Army Medical Service.—The following list of Surgeons obtained the number of marks specified at the recent Netley examination. The order of position of these gentlemen is not affected by the marks gained at this examination:—

Netley Marks.		Netley Marks.	
W. G. Macpherson ..	2951	J. E. Stuart ..	1866
R. J. Shaw Simpson ..	2897	Th. Ricketts-Morse ..	1974
F. W. Beid ..	2220	W. B. C. Deabls. . .	2030
E. V. A. Phipps ..	2425	J. M. Prendergast ..	1484
V. E. Hunter ..	1829	R. F. Bond ..	2049
A. Bard ..	2180	G. T. H. Thomas ..	2045
T. O'H. Hamilton ..	2147	G. M. H. Colman ..	1793
D. Semple ..	2260		

^ Gained the Montefiore Medal and a Prize in Pathology.

Indian Medical Service.—The following Surgeons were successful at both the recent London and Netley examinations. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley:—

Combined Marks.		Combined Marks.	
A. W. D. Leahy ..	5798	J. Crimmin ..	4637
B. W. Webb ..	5420	R. E. S. Davis ..	4592
C. R. Weir ..	5418	H. K. Fuller ..	4561
W. H. Burke ..	4924	W. H. Neilson ..	4301

a Gained the Herbert Prize and the Montefiore Second Prize.

b Gained the Martin Memorial Gold Medal and a Prize in Pathology

c Gained the Parker Memorial Bronze Medal.

University of Dublin.—The following degrees were conferred at a meeting held on Feb. 6th:—

BACHELOR IN SURGERY.

Alcorn, Samuel Alfred.	Crowe, Daniel.
Armstrong John.	Finegan, Joseph Patrick.
Cormack, Eugene.	Nason, Charles St. Stephen R.

BACHELOR IN MEDICINE.

Alcorn, Samuel Alfred.	Finegan, Joseph Patrick.
Boles, William Samuel.	Hamilton, Charles Wolfe.

MASTER IN SURGERY.—Charles St. Stephen Richard Nason.

DOCTOR IN MEDICINE.—Charles St. Stephen Richard Nason.

LICENTIATE IN MEDICINE.—Charles Joseph Fagan.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 28 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

A **CONSTANT READER** has forgotten to enclose his card as evidence of his *bona fides*. He is, nevertheless, thanked for the trouble taken in looking up the past history and doings of the notorious "David Jones, M.D.," and for the circulars and announcements relative thereto, which will be kept for future reference. We were aware that he had been struck off the "Medical Register" for a serious offence, and referred to the fact in our issue for January 24th, but the conviction and sentence were previously unknown to us.

REWARDS FOR HOSPITAL NURSES.—According to the *Court Journal* the institution of bronze earrings with "Merit" engraved on them is said to be contemplated by the authorities. These ornaments are to be given to female nurses who have distinguished themselves in hospital service during war.

GRATEFUL FOR MEDICAL SERVICES!—"How is your wife this morning?" inquired a doctor of one of his patients. "She is dead, I thank you," was the widower's answer.

F. F.—When poisoning by morphia is suspected an emetic of mustard or sulphate of zinc should be administered, and the patient should be kept in motion, a wet towel being at the same time fopped over the chest. Coffee, hot, in the form of an enema, and inhalations of amyl nitrite are of service. No attempt to induce vomiting will be successful if the poison has been received into the system by hypodermic injection, so that when this is known to be the case time should not be lost in resorting to this proceeding. Please send the cases.

ARTIS.—No attempt has been made, with which we are acquainted, to justify the action which called forth the remarks. You are quite correctly informed concerning the facts, and but for being unwilling to draw attention to an unavoury subject, we should have published them before this.

MR. CHAMBERLAINE does not give sufficient information to enable us to pronounce definitely upon the case. If he will furnish us with the necessary details we shall be happy to give it our best attention.

MR. G. E. P. N. (Shrivenham).—The treatment pursued in the case of Mary Shewry was reasonable with the limited knowledge at Mr. C.'s command, and we can hardly assume the censorship of that gentleman under the circumstance because the patient died suddenly. We are fully persuaded that the woman would have died under any circumstances; Mr. C.'s treatment probably had the effect of relieving her immediate sufferings.

DR. S. T. (Frankfort).—We shall be happy to draw the attention of our readers to the invention.

MR. M. D. M. (Charing Cross).—We do not see the utility of inserting the letter enclosed to us, the purpose for which it was designed being already served.

CVIVS ACADÉMIE.—Whether it is a weakness or not, it certainly is a characteristic feature of the English character to be generous, and to this must be attributed the occurrence you remark upon. The surgeon in question is deservedly popular, and enjoys a practice which enables him to carry out all the benevolent schemes which occur to him. We could easily do with more like him. The book has been published, and may be obtained through any bookseller.

DR. J. O. F.—We feel complimented by receipt of the F. R. for February, containing letter with quotation from the *Medical Press and Circular*.

MR. BARKINE (Sunderland).—A person with a dislocation of the hip-joint could, with assistance, limp for a distance of 100 yards.

INQUIRER.—The population of London (estimated to the middle of 1883) is 2,955,814, and that of New York 1,242,533. Although much greater, London is decidedly the healthier of the two—the death-rate being almost invariably higher in New York. This is probably to be accounted for by climatic influences, the extremes of heat and cold being much greater in the latter city; and also by the fact that London is the best drained and the most carefully watched city in the world.

MR. H. E. R.—Sorry we cannot afford space for your effusion, *ut scaps summa ingenta in oculis latent!*

A NOVEL CARGO.—The *Journal of Commerce* reports that the steamship *Hilda*, which has just arrived from Montserrat, W.I., has for almost her entire cargo lime-juice. She brings no less than 464 pipes, or nearly 50,000 gallons, the largest shipment on record. It is assigned to Messrs. Evans, Sons, and Co., Liverpool. The temperance movement has caused a very largely increased demand for the Montserrat productions.

DR. R. N. (Hampstead).—We will jog the memory of the gentleman concerned.

DR. H. D. (Bournemouth).—We have not seen the Directory in question; if such an item appears therein it is worse than a "ridiculous mistake," and you would have good grounds for an action for libel.

MR. H. M. M.—The drug has recently been introduced as a remedy for habitual constipation. We have it under notice, and hope to report our experience shortly.

DR. D. C. B.—The "Notes" will appear shortly.

W. C.—We have reason to think it was inadvertently introduced; and we have been assured that such a mistake will not again be made. May we remind you that the cases will require to be carefully gone through, and that it will be advisable for you to complete the preliminary steps at an early date.

MEETINGS OF THE SOCIETIES.

ACADEMY OF MEDICINE IN IRELAND (Medical Section).—Friday evening, Feb. 16th, at 8 o'clock.—Living Specimens: Dr. H. C. Tweedy, Two Cases of Locomotor Ataxy.—Specimens by card: Dr. G. F. Duffey, Farre's Tubercle of Liver.—Dr. J. W. Moore, Pulmonary Tuberculosis in a girl, set. 12, with Secondary Infection of the Intestines.—Dr. J. H. Benson, A Bladder showing Chronic Catarrh, with Secondary Abscesses.—Dr. J. V. Lentaigne, Ulceration and Perforation of the Intestines.—Dr. Redmond, Bright's Disease of the Kidneys complicated with Peritonitis.—Papers: Dr. W. J. Smyly, Sudden Change in the Colour of the Hair and Skin in an Infant.—Dr. H. C. Tweedy, Two Cases of Locomotor Ataxy.—Dr. J. V. Lentaigne, A Case of Ulceration and Perforation of the Intestines.

Vacancies.

Athlone Union, Athlone Dispensary.—Medical Officer. Salary, £140. Election, Feb. 16th.
Dublin, South.—Medical Officer for the Workhouse. Salary, £250, apartments, coal, gas, and attendance. Election, Feb. 15th.
Dunfanaghy Union, Crossroads Dispensary.—Medical Officer. Salary, £110. Election, March 7th.
Kent and Canterbury Hospital.—Assistant House Surgeon and Dispenser (one office). Salary, £50, with board, &c. Applications to be sent to the Secretary on or before Feb. 23rd.
Middlesex County Lunatic Asylum, Hanwell.—Assistant Medical Officer. Salary, £150, with board and residence. Applications must be sent to the Clerk to the Visitors, at the Asylum, on or before Feb. 20th.
Rochester and District Friendly Societies' Medical Association.—Resident Medical Officer. Salary, £300, and accommencement fees. Applications to be sent to H. T. Kybett, 55 High Street, Chatham, Kent, on or before Feb. 16th.
University College, London.—Dental Surgeon and Lecturer on Dental Surgery. Applications to the Secretary before Feb. 23th. (See Advt.)

Appointments.

BERRY, J. B., M.R.C.S., House Physician to the Royal Free Hospital.
BOOTH, Mr. E. H., House Surgeon to the Seamen's Hospital, Greenwich.
EASON, A. M., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer for the Lytham District of the Fylde Union.
HOAR, C., M.R.C.S., one of the House Surgeons to University College Hospital, London.
MURRAY, G., L.R.C.P.Ed., L.R.C.S.Ed., Assistant Medical Officer to the Infirmary, St. George's-in-the-East.
ROSS, Mr. E. F., one of the House Physicians to University College Hospital, London.
TINSELEY, S., L.F.F.S.Glas., Medical Officer for the Weetwang District of the Driffield Union.
WALKER, J. McC., M.B., C.M.Glas., Medical Officer for the Western District of the Haltwhistle Union.

Births.

BOYCE.—Feb. 5th, at Stillorgan, the wife of J. Wallace Boyce, M.B., of a son.
BOYS.—Feb. 6th, at Lodway Villa, Bristol, the wife of A. H. Boys, L.R.C.P.Ed., of a son.

Marriages.

AMBROSE—MULLIN.—Feb. 6th, at Saint Mary's Church, New Ross, Thos. F. Ambrose, National Bank, to Mary Agnes (Birdie), eldest daughter of Peter Mullin, M.D., New Ross.
COTTON—SKEY.—Feb. 6th, at St. Mark's, Notting Hill, Capt. Stapleton Cotton, Royal Body Guard, to Rosa Sophia Metcalfe, only daughter of the late Fred. C. Skey, C.B., F.R.S., President of the Royal College of Surgeons of England.
HARBORD—BLAND.—At the Parish Church, Rathfarnham, co. Dublin, E. C. Mordaunt Harbord, M.A., T.C.D., third son of Colonel E. Harbord, Bath, to Margaret Grace, only surviving daughter of the late James Stone Bland, Surgeon R.N.

Deaths.

CHATER.—Feb. 5th, at Tenby, George Chater, F.R.C.S., aged 71.
BEATTY.—Feb. 8th, at Cinderford, Gloucestershire, suddenly, Robert Bryan Beatty, M.B. T.C.D., youngest son of the late Frederick Beatty, Esq., of Incepark, co. Wicklow, aged 34.
HAY.—Jan. 29th, at Lusk, N.B., James Hay, M.B., aged 33.
REECE.—Feb. 4th, after a few hours' illness, Henry Reece, M.R.C.S., L.S.A.Lond., of 168 Piccadilly, London.
SMITH.—Jan. 19th, at Bangkok, Siam, George S. Smith, L.R.C.S.Ed., Surgeon to H.B.M. Consulate-General, aged 43.
TOULMIN.—Feb. 4th, at Thurloe Square, S.W., Frederick J. Toulmin, F.R.C.S., formerly of Clapton, Middlesex, aged 84.

UNIVERSITY COLLEGE, LONDON.—The office of Dental Surgeon and Clinical Lecturer on Dental Surgery in University College Hospital is vacant. Applications for the appointment will be received on or before February 15th.
TALFOURD ELY, M.A., Secretary.

The Medical Press and Circular.

THE TREATMENT OF SOME OF THE FORMS OF VALVULAR DISEASE OF THE HEART. (a)

By A. ERNEST SANSOM, M.D., F.R.C.P. Lond., Physician to the London Hospital; Senior Physician to the North-Eastern Hospital for Children, &c.

(Concluded from page 136.)

LECTURE III.—MITRAL STENOSIS—(Continued).

Morbid Anatomy—Physical Signs—Differentiation from the Lesion which Induces Regurgitation—Rise and Progress of the Disease resulting in Stenosis—Compensation—Special Treatment in Mitral Stenosis—Complications of Mitral Disease—Pericardial Adhesions—Embolism.

I.—*Presystolic murmur developing insidiously without signs of rheumatism.*—A lady (Mrs. M—), æt. 52, came under my care in 1876 for dyspepsia, with very slight jaundice. She manifested no history of, nor predisposition, to rheumatism. I had frequent opportunities of examining the heart, and there were no signs whatever of lesion. In January, 1877, there having been no signs other than an occasional slight dyspepsia previously, the patient complained of "fluttering of the heart," and I found, just right of the apex, a rough presystolic murmur abruptly terminated by the impulse. I do not think it possible that such sign could have been overlooked in my previous examinations; I can have no doubt that the lesion of stenosis developed gradually without any subjective signs to mark its onset. I have watched the case at intervals ever since: there have been no articular phenomena; the presystolic murmur has been attended with quasi-reduplication of the second sound, and a few months after its first being evident a short systolic murmur at the apex was observed also. The systolic murmur increased in intensity, the presystolic continuing to be entirely characteristic. During the whole period until the present, there have been no articular troubles, and the cardiac complication though giving rise occasionally to very slight symptoms, is, for the most part, and for long periods

accompanied by no signs of discomfort. This case affords evidence that in adults the morbid change can occur in a gradual and insidious manner with no rheumatic nor other notable phenomena to mark its onset and course. I have previously given many illustrations to show that a similar course is often manifested in the cases of children who come under treatment for the consequences of the cardiac lesion which has been so insidiously effected. (a)

II.—*Systolic murmur at apex becoming changed to presystolic murmur.*—The following notes are condensed from a report by my former house physician, Dr. J. Needham, by whom the case was carefully watched. John W. D—, æt. 18, was admitted under my care at the London Hospital on Oct. 17th, 1877. Patient had had so little subjective symptom that he said that, with the exception of chicken-pox, he had never been ill in his life until eight weeks ago. He had, however, been under treatment for psoriasis at intervals for nine years. His present illness was attended with pains in the limbs and abdomen. There was no effusion into the joints, and the temperature never rose above 100.2° F. On admission, a soft systolic murmur was noted in the mitral area, the outline of the heart, as determined by percussion, not differing from the normal. Two days after admission the systolic murmur was described as loud and conducted towards the left axilla. Seven days after admission there was a slight thrill at apex. Fifteen days after admission the note says: "The cardiac conditions are considerably altered. There is now a well-marked thrill at apex, and instead of the systolic murmur there is a well-marked harsh murmur increasing in intensity and terminated by a clear first sound; about two inches nearer the sternum, a blowing systolic murmur is distinctly audible." The systolic murmur (which was in the tricuspid area), subsequently disappeared, and the presystolic became louder, terminating with a sudden uncomplicated first sound. The patient improved under treatment, but suddenly, six weeks after admission, became epileptic.

In this case there was no history of acute rheumatism, though probably the psoriasis was an indication of a rheumatic tendency. In other cases we have distinct evidence that the murmur of mitral regurgitation developed in relation with acute rheumatism, may be, in course of time, accompanied by

(a) Delivered before the Medical Society of London.

(a) "Clinical Lectures on Diseases of the Heart in Childhood." *Medical Times and Gazette*, Dec. 27, 1879, p. 711.

the murmur of mitral stenosis. We may take for an example, the case of Lydia Grace P—, a child of eight, admitted under my care at the North Eastern Hospital in 1872. She suffered from acute rheumatism. Whilst under observation, a systolic murmur developed at the apex. She was discharged convalescent, and re-admitted in January of the following year, with a second attack of rheumatic fever. There was now evidence of mitral regurgitation with cardiac hypertrophy. She was again discharged convalescent, and re-admitted on Aug. 13th, 1873, with a third attack of acute rheumatism. She now manifested well-marked *presystolic* as well as systolic murmurs at the apex. She was again discharged convalescent. I do not think it necessary to multiply examples—I have observed many such—of this mode of induction of the condition of mitral stenosis. I may add, however, that it would appear that in some cases, the condition of regurgitation is *replaced* by that of stenosis. For example, in a child of nine (Elizabeth M.), a systolic bruit in July, 1869, was found to be accompanied by a *presystolic* in November, and two years afterwards, a *presystolic* alone was audible, terminated by a sharp and loud impulse.

III.—A *presystolic murmur developing insidiously, may subsequently be found to be accompanied by a systolic murmur.*—Arthur V., et. 8, was admitted under my care at the North Eastern Hospital for Children on Dec. 30th, 1874. He had never suffered from any definite illness, save measles and whooping-cough at three years of age, but he had frequently been ailing. He manifested a highly-pronounced *presystolic* thrill at the apex, and the *presystolic* impulse of the left auricle was easily demonstrated on the surface of the chest wall. A marked *presystolic* murmur was abruptly terminated by the impulse of the ventricle. There was evidence of enlargement of the right chambers, but not of the left ventricle. On Jan. 5th of the following year, symptoms of subacute rheumatism became manifest, and then a systolic murmur was evident at the apex. Subsequently, the systolic murmur became very loud, and heard over a wide area, whilst the *presystolic* was only audible at a point just below and internal to the left nipple. Signs of want of compensation now became more marked, and œdema, which, however, disappeared under treatment, supervened. Such a history is by no means uncommon, the signs of regurgitation supervene on those of stenosis, and the double lesion becomes manifest.

I hope that the evidence which I have brought forward may enable us to see in a clearer light the mode of development of mitral stenosis. This evidence, as I consider, tends to show that in a considerable number of cases, the origin and course are insidious and gradual. The disease is not independent of rheumatism, but is not accompanied by pronounced rheumatic phenomena; it is initiated by the form of endocarditis, which I sketched in my first lecture as manifested by no subjective sign, accompanied by no prominent symptom, and yet differing in no essential feature from that which occurs in obvious relation with rheumatism. The endocarditis which results in mitral regurgitation is more violent, so to speak, whilst that which initiates stenosis is more protracted, giving rise to a slower formation of fibrous quasi-cicatricial tissue, which under the even pressure of blood in the auricle tends to form the smooth septum which has erroneously suggested a possible congenital formation.

Not all the cases of mitral stenosis, however, are originated in this manner. In some there has been, first, the induction, in association with the phenomena of acute rheumatism, of the lesion of mitral regurgitation; then has occurred probably a welding of the curtains and in the repeated attacks of endocarditis the changes have been slower than those which result in retraction of curtains, of cords, and columns to the ventricular wall.

By either of these modes produced it is probable that secondary changes take place in the diseased tissue. Under the pressure of blood the fibrous septum thickens, for it has to bear the chief strain of the auricular pressure, and not the ventricle, as in the case of mitral regurgitation. In some cases it undergoes calcareous degeneration; probably in others, where gouty signs are manifest, it becomes infiltrated with the earthy lithates.

Compensation in cases of mitral stenosis may be maintained, as in mitral regurgitation, for long periods. It may be even more simple in the former case than in the latter, for it is only a hypertrophy of the right ventricle, and not of both ventricles, that is needed to maintain it. The left ventricle not being dilated, continues to afford a sufficient *point d'appui*, and it only needs the *vis-à-tergo* of a strong right ventricle,

aided by a hypertrophied (or, at least, not enfeebled) auricle to urge a sufficiency of blood through the narrowed orifice. So long, therefore, as a good nutrition maintains the muscular power of right ventricle and left auricle, any special methods of treatment of a simple condition of mitral stenosis may be unnecessary. In course of time, however, the right ventricle or left auricle, or both, may begin to fail. Usually it is the former, but I have quoted a case in which it was markedly the latter, and in this, I have no doubt, the auricle failed on account of the great privations which the patient had undergone. The right chambers dilate on account of the pressure which is maintained within them if the compensating muscular power begins to fail. Then ensue the dyspnoea, the œdema, ascites, &c., which we are familiar with in analogous cases of mitral regurgitation. To restore compensation, we may use for the most part similar means to those which we have considered in respect of mitral regurgitation. When the gravest troubles of orthopnoea and dropsy have supervened, I have in many cases found that rest, combined with the administration of nutrients and tonics with digitalis, have restored the *status quo et ante* often for a considerable period.

Coincident with the use of means for increasing muscular power, I consider that small and repeated abstractions of blood are even more valuable in mitral stenosis than in mitral regurgitation. The relief of the tension of the right heart may be sensibly relieved even by a leech or two applied over the præcordium. Dr. Bedford Fenwick has narrated a case which is an amusing as well as instructive example of the value of blood-letting in failure of compensation in mitral stenosis. A patient of Dr. Andrew Clark's, at the London Hospital, manifesting the physical signs of mitral stenosis and aortic incompetency, had not improved by a month's treatment with rest, ether, senega, and digitalis. There was much dyspnoea, with signs of œdema of the lungs. The urine became scantier, the œdema increased, and coma appeared to be supervening. At this time the patient, in his half-consciousness, struck his own nose, and brought on a copious epistaxis. Shortly after consciousness returned, a copious diuresis followed during the night. In less than a week the œdema disappeared, and the patient became convalescent. I quite agree with Dr. Bedford Fenwick that abstraction of blood by leeches or cupping is too much neglected in the cases we are considering, and that it is to be justified both by theory and practice. (a)

As regards the special action of *digitalis* in restoring compensation in cases of mitral stenosis, I am not convinced that this is so markedly proved to be beneficial as in the cases of mitral regurgitation. I have found that in some instances, as shown by the sphygmograph, *digitalis* has restored regularity, whilst in others it has increased irregularity of pulse. I believe it to be most valuable where stenosis and regurgitation are combined. Where the right ventricle is chiefly at fault, I do not think its good effect is so manifest; where it can induce an efficient systole of both ventricles and co-ordinate them, then I think it is the more valuable. In failure of the right heart, therefore, in extreme mitral stenosis, I look hopefully to caffeine and to convallaria maialis.

M. Sée has narrated three cases of mitral stenosis in which the extract of convallaria was administered. In the first there was a marked diuretic effect, the quantity of urine increasing under treatment from an average of one litre to two and a-half and three litres, together with a great amelioration of the dyspnoea, which was manifest on exertion. In the second case, manifesting œdema, ascites and grave signs of cardiac failure, with a dose of one gramme per diem of extract of convallaria, marked diuresis occurred, and œdema disappeared in two days. Oliguria returned, and the dose was increased to 1½ gramme. In successive days the quantity of urine passed increased in the following rate:—600 grammes, 2,200, 2,400, 3,000, and then fell to 2,000 grammes, all signs of œdema and ascites having disappeared. The third case was the one in which diabetes mellitus co-existed with mitral stenosis. In this case a very marked indication of the symptoms of imperfect compensation is recorded.

Considering the absence of violence in the storm which, involving, the endocardium leaves behind it the condition of obstruction, we may ask whether such result is not more innocent than regurgitation? The question is a difficult one. We can point to many cases of re-

(a) "On the Use of Venesection in Cases of Heart Disease." By Bedford Fenwick, M.D., M.R.C.P., *Lancet*, Aug. 5, 1882, p. 179.

gurgitation where there has been an arrest of all morbid processes, and where fair health has been maintained for long periods of years. Such instances are, I think, less common in mitral stenosis—there is not a like quiescence, and degenerative changes or inter-current morbid phenomena are more likely to occur. The average age at death in 19 cases of mitral stenosis observed by myself was 35 years. In 42 fatal cases collected by the late Dr. Hayden it was 37·33 years.

In the cases both of mitral stenosis and of mitral regurgitation, however, it is not alone with the single dynamical problem of the restoration of muscular compensation that we have to deal. In every case we have to weigh the probability of complications arising—complications so intimately associated with the conditions as present an essential matter for consideration in any question as to treatment. Such are (1) repeated attacks of pericarditis or endocarditis, and (2) embolism.

A patient who has once suffered from rheumatic affection of the endocardium is liable, of course, to a repetition of the morbid processes. With such, pericarditis is by no means infrequently associated. In children, I am strongly of opinion that pericarditis, when resulting in adhesion of the two layers of the pericardium, is a grave source of danger, spoiling the chance of compensation, and greatly interfering with the beneficial results of treatment. In cases in young people where compensation fails, even under suitable treatment and good nutrition, where evidences of cardiac hypertrophy and dilatation are in excess of those which usually accompany the valvular lesion, we may, I think, generally conclude that the pericardium is adherent.

I.—An accident of the condition, both of regurgitation and stenosis (especially the latter), yet intimately connected with them, is the *embolism*. The consideration of this is often forced upon us when the question occurs as to treatment.

Let us consider this matter from its *clinical* aspect. 1. A case presents itself to us with symptoms of cough and dyspnoea. The onset of these symptoms has been sudden, perhaps initiated by a rigor. There may have been slight pyrexia, or none. The characteristic feature is that, after a short time, when the cough has been attended with mucous and frothy spittle, the expectoration is observed to be coloured with bright blood. In many such instances we may find localised patches of dulness in the upper or the lower thoracic regions, with a few muco-crepitant râles; in others, neither dulness nor moist sounds can be detected.

We examine the heart and find evidence of the existence of mitral stenosis or (less frequently) mitral regurgitation. The existence of these signs, especially when the lesion is in the upper lobes, may cause us to fear the advent of pulmonary phthisis, but observation shows us that hæmoptysis may occur again and again, the changes of tubercle are not manifest. Or whilst a case is under treatment for the symptoms of ill-compensated stenosis or regurgitation, a sudden attack occurs of dyspnoea, with physical signs of a localised broncho-pneumonia. In some cases the outline of the dulness can be delineated as a defined triangle. It is broncho-pneumonia; but its origin may be entirely independent of catarrhal influences, and it has a special feature—the occurrence of hæmoptysis. It is rarely that a case of mitral stenosis goes through its course without the manifestation of some such phenomena. Dr. Hayden records that hæmoptysis was noted as a symptom in 44 cases out of 81 of mitral stenosis (54·3 per cent.). The history of fatal cases generally shows the repeated development of such areas of condensed lung. Morbid anatomy affords the clue to the interpretation of these phenomena. In many instances the right auricle is found to contain, adherent to its internal surface, fibrinous coagula, and detached masses from such have been found to block branches of the pulmonary artery. From such infarctions result the appearances formerly described as “pulmonary apoplexy.” The infarct may in many cases be undiscoverable, for the plug undergoes fatty degeneration and solution, and the lung tissue may present no naked-eye alterations. I am inclined to think, however, that what is true of the grosser is true of the finer changes, and that the hæmoptysis, or the limited broncho-pneumonia of mitral stenosis are due to plugging (it may be of small twigs) of branches of the pulmonary artery.

Now, as regards treatment when such phenomena are

manifest. In the first class of cases, where no sign of ill-health has been previously prominent, I could accept the occurrence as evidence that compensation is disturbed. There is an abnormal retardation of the circulation in the right chambers of the heart, and we are called upon to use some of the means we have described for increasing the power of ventricles. In all cases it will be advantageous if we can decrease the tendency to coagulation of the blood, even if we cannot promote the solution of that already coagulated. Dr. B. W. Richardson has advised the administration, in cases of fibrinous separation within the heart and vessels of the circulation of large doses of ammonia (five minim doses of the liquid ammonia in cold water or cold milk every half hour in some cases). Where there has been imminent danger from pulmonary embolism I have employed this plan, and the patient has recovered. I think, therefore, that it is applicable in the cases of less imminent danger of blockings with smaller coagula which we are considering. When in mitral stenosis or mitral regurgitation there are developed signs of broncho-pneumonia, I think it is advantageous to give ammonia, though it may not be in such heroic doses as those mentioned where there was danger of complete or extensive plugging of the pulmonary artery. Prof. Gerhardt advises carbonate of soda administered by inhalation.

II. The phenomena of embolism may be manifest on the arterial side of the circulation. As in the case of those which affect the venous, these may be manifest (a) in patients who have not shown evidence previously of cardiac distress (b) in those who are under treatment for cardiac disease. I have in my lectures on “Diseases of the Heart in Childhood” (a) given ten examples of the sudden manifestations of lesions of the nervous system in children who had never suffered from any rheumatic affection, and of these ten six showed the signs of mitral stenosis. The nervous lesions were hemiplegia, hemianæsthesia, hemichorea, and epilepsy. In such cases there can be little doubt that fibrinous coagula detached from vegetations about the mitral orifice were carried by the current of blood and blocked some of the arterial branches distributed and some part of the cerebro-spinal system.

In cases under treatment for cardiac diseases the one sign which I have found to indicate the probability of embolism is a sudden rise of temperature of the body. The locality of the embolism is not immediately indicated by the symptoms. The relative frequency of the sites of embolism, according to the returns from the Pathological Institute, Berlin, are kidneys (75 per cent.), spleen (57), brain (20), intestine, heart and liver (7), skin (5), spinal cord (3), thyroid body and eye occasionally. In my own cases the sites were—spleen (11 cases), kidneys (6), brain (5), retinal artery (1), intestines one.

The occurrence of any of the phenomena of embolism in cases of valvular disease is an indication either of recent development of endocarditis with the formation of vegetations, or of the detachment of an old vegetation, or of the occurrence of ulcerative endocarditis. In the last case the sites of embolism are usually multiple, and treatment is of little or no avail. In the other cases the first essential for treatment is the maintenance of rest and tranquillity of heart. The blood should, so far as possible, be rendered as fluid and non-coagulable as possible, and to this end it should be maintained alkaline by the administration of ammonia or soda. The subject of the treatment of the secondary effects produced by the embolism—effects varying according to its site—of course I cannot approach on this occasion. (b)

(a) *Medical Times and Gazette*, Dec. 27, 1879, p. 712.

(b) I have to thank Messrs. Savory and Moore and Mr. Brownen, F.C.S., for exhibiting not only the various preparations of convallaria, but the alkaloids (convallarin and convallarmine) obtained from the plant.

WE are informed that steps will shortly be taken to perpetuate the memory of the late Dr. Shinkwin, of Cork, by a memorial of some kind. The exact form has not yet been decided on, but it is probable that a memorial tablet or a medal for annual competition may be instituted.

RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S Eng., M.S. Lond.,
Surgeon to the London Hospital.

PART II.—*Reported Cases of Recovery—Treatment—Conclusion.*

(Continued from page 137.)

FEW will dispute the less severity of an incision two or three inches long, compared with one of twice the length. Experience alone can determine whether the wound in the bladder should be sewn up or not. If we could unreservedly trust to the genuineness of Dr. Walter's case, the rent might be left to take care of itself; and we might find some justification for this in the frequently jagged and contused edges of the aperture, which render primary union unlikely to occur. Before the edges have cleaned and adhered the stitches might cut their way out; whereas, if the rent were left alone, the bladder being kept empty, adhesion of the edges might soon occur, and intestine might become attached to the back of the bladder. If the rent is sewn up, carbolised silk would hold better and longer than catgut. Washing out the peritoneum with tepid water seems to be objectionable. A warm solution of thymol or sanitas would be less favourable to the introduction of impurities and germs. Mr. Heath is convinced of the inutility and harmfulness of a drainage tube passed through the abdominal wound into the pelvis; but he seems to regret that he did not pass a tube through the recto-vesical pouch of the peritoneum and the wall of the rectum, bringing it out at the anus. I feel very strongly that this would be a dangerous procedure, and that the risk of gas getting into the peritoneal cavity would far outweigh any advantages arising from the dependent opening. If another opening be needed, and I am inclined to think that it is, the most efficient means of securing free exit of urine and giving perfect rest to the bladder would be to combine lateral lithotomy or cystotomy with abdominal section, performing the abdominal section first with antiseptic precautions, and sewing up the rent in the bladder, and afterwards making the perineal opening. Doubtless, the combined procedure may appear severe; but an intra-peritoneal rent in the bladder is a desperate injury, requiring to be met, not by desperate, but by thoroughly effectual means of treatment, directed first to the removal of urine already effused, and secondly to the prevention of further escape.

Dr. Vincent, for whose monograph I am indebted to Mr. Heath, advocates cystoraphy by a combination of two kinds of suture, which may be termed the sero-muscular and the serous suture respectively. The sero-muscular suture consists in entering the needle a little way from the edge of the rent, carrying it down as far as the mucous coat, and then making the thread traverse the edges of the rent between the muscular and mucous tissues, and bringing it out at a corresponding point on the opposite side. This suture draws the edges of the rent together, and by avoiding penetration of the mucous coat, obviates all danger of the sutures finding their way into the bladder and becoming calculi. The serous suture is effected by entering the needle at some distance from the edge of the rent, carrying it under the peritoneum for about a quarter of an inch or more, then bringing it through the serous coat, drawing the thread across the rent, and repeating the process on the other side. When this suture is tied the peritoneal surfaces on either side of the wound are brought into contact, and, according to Dr. Vincent, rapidly unite. The serous and the sero-muscular sutures may be alternated with advantage. Dr. Vincent attributes the failure of abdominal section and cystoraphy in Mr. Willett's and Mr. Heath's cases to the length of time which elapsed before the operations, and to the ineffectual character of the sutures. In his experiments on dogs he found that the procedure was uniformly

successful when practised within eight and a half hours, but constantly failed through urinary intoxication when performed twenty-four or twenty-five hours after the bladder was wounded. He deprecates founding any canon for treatment upon Dr. Thorp's case.

Occasionally it happens that the practitioner, whilst convinced that a rupture of the bladder has taken place, is in doubt whether the rent is intra-peritoneal or extra-peritoneal. As it is of the highest importance to act promptly, an exploratory incision should be made immediately above the pubes, and the bladder reached before the peritoneum is opened. If no evidence of an extra-peritoneal rent is forthcoming, the peritoneum can then be divided, and the posterior surface of the viscus exposed. By proceeding cautiously, the surgeon may avoid the possible error of laying open the peritoneum for an extra-peritoneal rupture.

As illustrating the advantage of early incision above the pubes in the peritoneal rents, I would again call attention to the case of recovery reported by Dr. A. V. Williams in 1855. Probably, a good many more recoveries after extra peritoneal rupture would have been chronicled if surgeons had acted more boldly and promptly in these dangerous cases. In a valuable paper on rupture of the bladder following stricture of the urethra, already referred to (a) Dr. Gouley has related a case which came under his care in the initial stage, and subsequently passed under the treatment of Dr. Stephen Smith. The patient was a man, *æt.* 36, who had suffered from dysuria, and other symptoms of advancing stricture for two years prior to admission to the hospital. Whilst straining to pass water he felt something give way within him, and experienced severe pain in the abdomen. On admission to the hospital the patient had not made water for forty-two hours. He lay in bed with his knees drawn up, and the abdomen was tense, tender, and tympanitic. A capillary whale-bone bougie was passed, and over this a tunnelled catheter, six ounces of clear urine being drawn off without yielding much relief. On the second day after admission there were redness and tenderness over the right iliac fossa, but no deep incision was made till the 29th day, when pus and urine were emitted from a cavity above the pubes. The patient survived till the 44th day after the accident. At the autopsy a rupture of the anterior wall of the bladder was found about the middle of the vertical diameter, and a little to the right of the median line. The opening in the mucous coat was somewhat rounded, and large enough to admit the index finger. The muscular and fibrous coats showed a vertical laceration an inch in length. A cavity existed in front and around the bladder. Dr. Gouley himself in his comments on the case, regrets that an exploratory incision was not made. He advocates treating these cases by cystotomy combined with a supra-pubic incision, remarking that the latter is necessary for the evacuation of urine already extravasated, and the former for the prevention of further escape of urine from the bladder. Another instance in which an exploratory incision would have been beneficial has recently occurred in the practice of Dr. Walker at the Bootle Hospital. (b) The case was seen in consultation with Mr. Reginald Harrison, who diagnosed a rupture of the bladder.

The patient was a fireman of a steamship, *æt.* 40, who went to bed in his usual good health, and woke suddenly between one and two o'clock in the morning, wanting to pass urine, and complaining of intense pain all over "the privates." A medical man who was summoned passed a No. 8 gum-elastic catheter, and drew off blood in considerable quantity. Early in the morning the patient was admitted into the hospital. His abdomen

(a) *New York Medical Record*, 1872, p. 457. Dr. Gouley refers to a prior paper by Dr. Cruise in the *Record* for August, 1871, p. 241; and to a paper by Dr. Willard Parker on "Cystitis and Rupture of the Bladder treated by Cystotomy."

(b) *British Medical Journal*, Dec. 16th, 1893, p. 1207.

was distended, dull on percussion, and very tender over the bladder. The perineum was ecchymosed. During the day he passed about thirty ounces of blood. After the diagnosis of rupture of the bladder had been made the treatment consisted in the retention of an india-rubber catheter and ablution of the bladder with weak carbolic lotion (1 in 100). An erythematous rash characteristic of extravasation began to appear over the right iliac region extending halfway down the thigh. Vomiting set in, and great prostration, and the patient died on the fourth day after the rupture. There was a cavity about the size of an orange behind the symphysis pubes filled with blood clots. A rupture was found two inches in length in the anterior wall, commencing an inch from the neck, and extending to two inches from the apex. The urethra was normal. There was nothing whatever to account for the rupture, the patient averring that he had always been a temperate man, free from venereal diseases, and had not sustained any injury prior to the rupture. Mr. Harrison thinks it probable that the rupture was really due to an injury which escaped notice. The character of the rent, the quantity of blood effused into the pelvic areolar tissue and in the rectus muscle, and the ecchymosis of the perineum, point to injury rather than to spontaneous rupture. A supra-pubic exploratory incision made immediately after diagnosis would have afforded the patient the best chance of recovery.

The treatment of rupture of the bladder in the female must be conducted on the same principles as in the male. Laparotomy is indicated as strongly as in the male for intra-peritoneal rents, and incision through the anterior vaginal wall into the bladder will naturally take the place of median or lateral cystotomy. In any doubtful case exploration of the viscus, either by dilating the urethra or by vaginal cystotomy, might be undertaken as a preliminary measure.

Looking to the extreme violence which often occasions rupture of the urinary bladder, to the injurious character of the fluid effused, to the variety of conditions and ages of the patients, to the frequent complications to the doubts which often beset diagnosis, and to other obstacles to successful treatment, surgeons can scarcely expect to rescue many who become the subjects of this dangerous lesion. Fortunate as it is that the accident is rare, the very rarity militates against the recovery of patients, for the attainment of personal experience in diagnosis and treatment becomes impossible for the individual surgeon. The recorded experience of many observers, combined into one view, must remedy this defect; and it has been with the object of rendering that experience more easily accessible to those who may meet with cases of the kind, and are desirous of acquainting themselves with the practical details of previous observations, that I have treated the subject at length. Entertaining a doubt similar to that expressed by Mr. Willett in 1876 whether a single unequivocal recovery after an intra-peritoneal rupture has occurred, I do not in this age of antiseptics absolutely despair of a time arriving when it can no longer be said, with Gross, "all the mischief that can be done is done in the first instance by the escape of urine into the peritoneal cavity, from which it will be out of the power of the surgeon to remove it, or to prevent its pernicious effects;" or with Cusack, "in accidents of this nature the surgeon has generally to lament the imperfection of his art while he witnesses the progress of the unfortunate patient to the termination of his sufferings;" or with Syme, "if the rupture takes place above, or within, the reflection of the peritoneum, there cannot be the slightest chance of escape."

It is not by standing still and relying upon old methods which have conspicuously failed that future success can be obtained. Neither can any advantage be expected by placing confidence in the methods of treatment, various as they have been, which have been adopted in the equivocal cases published as instances of

recovery after intra-peritoneal rupture of the bladder. Examined apart from the individual claims of the cases themselves to the acceptance of surgical authorities, the methods employed do not fulfil the two cardinal indications for successful treatment. The long list of fatal cases and sound surgical reasoning alike urge upon practitioners the advisability of giving a fair trial to means that appear likely to prove thoroughly efficient. Failures there will be, for failures are often the necessary preliminaries to success. The history of abdominal surgery illustrates this, and abundantly testifies that the best results are the reward of judicious boldness. It has been well said by Mr. Bryant that surgeons have been looking for a satisfactory means of dealing with intra-peritoneal rupture of the bladder. Unfortunately, this discovery has not yet been made; neither are surgeons in agreement with each other. Further experience alone can decide between the conflicting views; and surgery will achieve no unimportant triumph when occasional and indubitable recoveries are ensured by improved methods of treatment.

FERROCYANIC TEST PELLETS AS A CLINICAL TEST FOR ALBUMEN. (a)

By F. W. PAVY, M.D., F.R.C.P. Lond., F.R.S.,
Physician to and Lecturer on Medicine at Guy's Hospital.

MOST, I think, have felt, who have stopped to give consideration to the matter, that it would be exceedingly desirable if something more convenient than the method of procedure with heat and nitric acid, which has been in use so long, were placed at our command as a reliable test for albumen. At least, such is the expression which has, from time to time, fallen from those I have met, and I have been so strongly impressed myself in this way as to have been induced to turn my attention towards endeavouring to meet the want.

The convenience of the cupric test pellet for sugar inclined me to look for something that could be kept and employed in a solid form, and I started with the view that to be suitable for the purpose it must be freely and quickly soluble, devoid of objectionable physical properties, and a sharply marked and reliable precipitant of albumen.

During the last two or three years I have carried metaphosphoric acid in my urinary pocket case, and have frequently been in the habit of otherwise employing it. It is known to constitute an excellent test for albumen, and I tried for some time to bring it into a convenient form for use. In a pure state it is a glacial body, which, although deliquescent, does not quickly dissolve. Kept in fragments they stick together in such a manner as to prove troublesome at the time of use. I mixed the acid with other agents, as citric acid, sulphate of soda, chloride of sodium, and cane sugar, but I failed to obtain a satisfactory product. Thus finding that I could not succeed in getting what was wanted with metaphosphoric acid, I looked around for another suitable agent.

Yellow prussiate of potash and acetic acid employed together have long been known to furnish a valuable test for albumen. There may be other tests as good, but I think it may be said that there are none that can be spoken of as actually better. Citric acid may be made to take the place of acetic acid, and thus a test capable of being kept and used in a solid form is supplied. The precipitant of the albumen is ferrocyanic acid, and this is liberated just as effectually by citric as by acetic acid.

I at first thought that it would suffice simply to mix the yellow prussiate of potash and citric acid in the proper proportions, and compress into a pellet to obtain the test in the form I wanted. Experience, however,

(a) Communicated to the Clinical Society of London, February 9, 1883.

soon showed me that the matter was not so easily to be disposed of. Difficulties presented themselves which have taken time and consideration to overcome. With the willing and able assistance, however, which Mr. Cooper has rendered in carrying out the mechanical operations I have suggested, a pellet has been produced which seems, as far as I can at present judge, to supply all that can be desired. Its components are the sodic ferrocyanic and citric acid. Grounds exist for the employment of the sodic instead of the potassic ferrocyanide.

All that is necessary in using the pellet is to crush into a powdered state within a folded piece of paper with a silver or other coin from the pocket, or in any other way that may suggest itself, and to run into an ordinary-sized test tube, and pour in the urine to be examined to the height of about an inch. On simply agitating freely, without the application of heat, a precipitate will immediately, or almost immediately, appear when albumen is present. The test is so delicate that the smallest amount of albumen gives rise to a distinctly recognisable opalescence, and with a larger quantity a dense white precipitate is produced. Instead of crushing the pellet it may be broken in half, or placed whole in the urine. Used in this way it takes a minute or so for it to be dissolved and the reaction to be produced.

An estimate may be found of the amount of albumen present by allowing the precipitate to settle and reading off its height in proportion to the contents of the tube in the same way as is done after the application of heat.

As no employment of heat is required in the application of the test, it is not necessary that a test tube should be used. A wine-glass or medicine bottle will answer instead, and the quantity of urine should be kept down to about that recommended when a test tube is used. Enough acid exists in the pellet not only for liberating the ferrocyanic acid from the ferrocyanide, but for more than neutralising the alkalinity that is likely to belong to a specimen of urine limited to the quantity which has been recommended to be taken. Through this circumstance the test acts equally well with alkaline as with acid specimens of urine.

Phosphates do not interfere with the validity of the reaction given by the test. They not only are not liable to be precipitated by it, but the acid present will promote the solution of phosphates already deposited.

Should the urine be turbid from lithates it must be cleared by warming before the test is employed. A number of ways in which this can be done will readily suggest themselves without recourse to the use of a spirit-lamp where no spirit-lamp happens to be at hand.

If thought proper the test may be used in the same manner as some persons are in the habit of employing strong nitric acid—viz., by bringing the specimen and the test into contact with each other without admixture, and looking at the line of junction for the precipitate. Thus used the pellet should be dissolved in a little more than sufficient water to cover it, and the urine then allowed to flow gently down the side of the test tube until a stratum of about half an-inch in height has collected. The lamina of precipitate which is formed from specimens containing a minute amount of albumen, comes out denser and more sharply defined than with nitric acid. Further, if the contents of the tube are afterwards shaken together, a diffused precipitate is visible, whilst in the case of the strong nitric acid the precipitate disappears.

With urine containing oleo-resinous matter consequent upon the administration of an oleo-resin medicinal, it is known that nitric and other acids occasion a precipitate. The same will naturally occur with the ferrocyanic pellets, and this is the only fallacious indication that I am at present aware belongs to the test. Error from this cause, whenever the conditions permit it to be presented, must be guarded against in the same way as has been hitherto done under the employment of nitric acid.

Since this communication was written I have seen the albumen precipitate test papers introduced by Dr. Oliver, of Harrogate. They certainly form a very neat and elegant adaptation. Whilst encountering the difficulties that presented themselves with the production in a satisfactory state of the ferrocyanic pellets, the idea crossed my mind of papers soaked separately in the two agents and dried, but I did not act upon it, as I thought the presence of the paper in the test tube would be undesirable, and that it would be best, if possible, to keep from any extraneous substance. In the pellets there is nothing besides the two agents actually constituting the test, and their nature is such as to be perfectly harmless in every way. Properly preserved in a bottle, I have no reason, from the opportunity I have yet had of judging, to think otherwise than that they will keep for an indefinite time. They are made by Mr. Cooper, of 58 Oxford Street.

Clinical Records.

CASES IN PRIVATE PRACTICE.

By JOHN W. MARTIN, M.D.,
Sheffield.

Acute Rheumatism—Heart Affected—Area of Dulness Enlarged—Heart's Action Irregular—Impulse, weak and diffused—Well-marked Obstructive Mitral and Aortic Murmurs—Hepatic Enlargement—Slight Jaundice—Albuminuria—Anasarca—Ascites—Treatment—Recovery.

On the 7th of January, 1878, I was asked to visit W. S., æt. 17, suffering from general dropsy. I found him propped up in bed in a truly lamentable condition. He presented the appearance of a huge water-bag. Face puffed. Abdomen, arms, hands, thighs, legs, and feet, all swollen to such an extent, that the skin seemed ready to burst. Eyes suffused and jaundiced. Cheeks and lips cyanosed. Veins of the neck swollen and pulsating. Dyspnoea extreme, rendering it impossible for him to lie down. General dulness of the percussion note over the whole surface of the chest, back and front. Respiration, tubular, and in a few patches, coarse moist crepitation heard. Not much cough or expectoration. Area of cardiac dulness enlarged, measuring $5 \times 4\frac{1}{2}$ inches from upper border of 3rd rib on the left side, and from the left margin of the sternum at the articulation of 5th rib with sternum on the same side. Impulse, weak and diffused; action, irregular and intermitting; first sound distant, indistinct, and muffled by a well-marked *bruit de souffle*, which distinctly preceded and almost replaced it; second sound distinctly heard at the base, accentuated, and preceded by a loud, rough, blowing murmur, which was prolonged into the arch of the aorta and carotids. The girth of the abdomen, at the umbilicus, measured 50 inches. The umbilical sulcus was completely obliterated. The ascites was so extensive, that it was impossible to examine into the condition of the liver and spleen. He complained, however, of great weight and a dull continuous pain in the right hypochondriac region, together with pain in the right shoulder. There was distinct jaundice of the skin. Bowels costive; motions, clay-coloured, and very offensive.

Passed about ten ounces of urine, bile tinged, and depositing lithates freely. (Tested subsequently, it was found to contain albumen.) No joint affections, nor had there been from the first.

His history may be briefly stated as follows:—Previous to present illness he had been a fairly healthy lad. The mother had been a martyr to rheumatism and heart disease, from which she died some months previous to the commencement of this lad's illness. He had been working in a pit in which there was a good deal of water, and assigns the latter as the cause of a severe attack of acute rheumatism which he contracted in the month of October, 1877. I saw him at the outset of that attack, and, in the course of my examination, found that the heart was affected, loud mitral and aortic bruit being then distinctly to be heard. I did not find it convenient to take up the attendance at that time, and recommended them to call in another medical man, warning them that the attack promised to be a very severe one.

From that time to the date of my being called in again, the boy was unable to leave his bed; and just before my seeing him the case was pronounced hopeless by his attendant, an opinion thoroughly justified by the symptoms presented.

It will not be necessary for me to enter into a minute detail of the treatment, which extended over a period of six weeks, and which, contrary to all my expectations, was attended by the happiest results. It may be briefly summarised as follows:—

At my first visit I made numerous punctures with a tenotomy-knife in both lower extremities, which gave exit to a profuse flow of serum, and placed him upon a mixture containing nitrate of potash, spirits of nitrous ether, tincture of squill, and infusion of digitalis; I also ordered drachm doses of compound powder of jalap to be taken every second or third night for three doses. These measures were followed by rapid and steady improvement. I repeated the punctures on the fourth day of treatment, and again on the seventh. The jalap acted freely upon the bowels, and the mixture seemed to have the effect of producing a largely increased flow of urine. The oedema of the lower extremities, and the anasarca of the face, and upper extremities, rapidly subsided. The thoracic symptoms improved wonderfully—the patient being able to lie down at the end of the fifth day. The heart's action became stronger and steadier, accompanied by a corresponding improvement in the state of the pulse. The lungs became more resonant, and the râles disappeared. Respiration still remained harsh and tubular. His appetite became ravenous. The state of the liver and the ascites remaining unchanged. About the eighth day I altered the mixture for one containing nitro-muriatic acid, spirits of nitrous ether, tincture of squill, and infusion of digitalis, and ordered a pad, wet with a fairly strong lotion of nitro-muriatic acid, to be applied over the liver, then covered with gutta-percha tissue, and secured by a binder.

On the second day the lotion had produced an abundant papular rash and a state of intense irritation of the part. The jaundice was decidedly diminished, and the abdomen was greatly decreased in size—now measuring 44 inches. The patient's general health was evidently improving rapidly.

On the fourth day the girth of the abdomen was only 40 inches, and the lower border of the liver could be distinctly felt, extending three inches below the margin of the false ribs, and two inches beyond the median line, over towards the left side; its surface was quite smooth, and edge well rounded. There was a great deal of flatulent distension present in the bowels. The latter were moved daily, and the motions had become quite natural in their appearance.

From this time forward, the history of the case, was one of steady improvement. On the fifteenth day of treatment the boy was able to sit up out of bed. At the end of the third week, he was able to walk about. The amount of ascites present, and the size of the liver gradually and steadily diminished.

At the end of six weeks I stopped all treatment, trusting to the powers of Nature to effect the final reduction in the size of the liver and the ascites; the former was but a little over an inch below the false ribs, and no longer extended beyond the median line, as already described. The abdomen measured 34 inches at umbilicus.

Since then, the boy's convalescence has been all that could be desired. He is now in the enjoyment of good health (August 14th, 1878). No trace of ascites or hepatic enlargement being present. He is able to engage in his usual occupation, and to take any amount of active exercise. Valvular lesions remained when last seen, August, 1879.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 29, Madras 37, Paris 26, Geneva 22, Brussels 25, Amsterdam 30, Rotterdam 32, The Hague 16, Copenhagen 27, Stockholm 34, Christiania 17, St. Petersburg 41, Berlin 25, Ham-
burgh 29, Dresden 23, Breslau 30, Munich 31, Vienna 29, Prague 33, Buda-Pesth 30, Trieste 35, Venice 31, New York 25, Brooklyn 23, Philadelphia 23, Baltimore 38.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

PATHOLOGICAL SECTION.

A MEETING of the Pathological Section of the Academy of Medicine in Ireland was held on Friday evening, February 2, 1883, in the Albert Hall, Royal College of Surgeons.

Mr. BENNETT, Sectional Secretary, read the minutes of the previous meeting, which were confirmed.

EXHIBITION OF SPECIMENS.

Dr. C. F. MOORE exhibited a living patient, a strong woman, *æt.* 71, suffering from molluscum simplex. Neither her children nor grandchildren, nor any relative had a similar disease. The growths commenced twenty-five years ago without pain or injury to her health, in size varying from a small shot to that of a small grape, some sessile, some pendulous, growing on the face, neck, hands, chest, and arms; none on the lower limbs.

Mr. ABRAHAM showed microscopic mountings of new blood-vessels inoculating in granulation tissue among the meshes of a sponge skeleton after grafting.

Dr. WARREN showed an example of strangulated obturator hernia, which had been discovered *post mortem*.

Mr. WHEELER showed an arm amputated for compound fracture with extreme laceration; also a drawing of erectile tumour of the forearm, removed successfully from a boy, *æt.* 16, by excision; also a cast of congenital deformity of the hand, consisting in the absence of the little and ring fingers with rubbing of the middle and index, the thumb being normal.

PENETRATING WOUNDS OF THE BLADDER.

Mr. STOKES exhibited the bladder of a patient who had been recently under observation in the Richmond Hospital suffering from an exceptionally rare form of penetrating wound of the bladder. The patient, a youth, *æt.* 16, employed in an iron foundry establishment, was playing with a companion at vaulting over a pair of long forger's tongs. Failure attended one of his attempts to clear the instrument, and one of the long handles passed through the anus into the rectum a considerable distance. The boy fell, and the handle of the tongs was promptly removed by his companion. When brought to hospital he was in a state of great collapse. His sufferings were extreme. There was some slight hæmorrhage from the rectum, and the urine, when drawn off, was found deeply tinged with blood. On the second day all the symptoms were much aggravated. The abdomen became tympanitic and swollen, the pain agonising, and there was great vesical irritability. On the third day the patient became delirious, in which condition he remained until released from his sufferings, seventy-four hours after the accident happened. The autopsy revealed a perforation of the anterior wall of the rectum, about an inch and a-half from the anus. Here the instrument had passed into the bladder through the trigone and emerged at the fundus of the organ, opening into the peritoneal cavity, in which there was a large quantity of purulent fluid. There were well marked signs of extensive peritonitis. The author referred to the three somewhat analogous cases published by Mr. Prescott Hewett, M. Bué, and Mr. Bryant, giving the leading particulars of each, and also to the cases mentioned by M. Howel and M. Joubert de Lamballe. The question as to what is the chief factor inducing peritoneal inflammation in these cases was likewise discussed, the author inclining to the belief, from the evidence afforded by several instances of vesical rupture, intra-peritoneal gunshot wounds of the bladder, and also the experiments of MM. Vincent and Murzel, that urine, when first extravasated, and before any decomposition of its constituents takes place, is comparatively innocuous; and the practical deduction would be, provided no distinct contra-indication existed, the desirability in such cases of promptly securing a free exit for the urine by cystotomy or laparotomy before the changes take place which as a rule lead to such disastrous consequences. In the case the author brought under the notice of the Section neither of these operations could be contemplated, owing to the extreme condition of prostration the patient was in when

admitted into hospital, a condition from which he never rallied.

In the discussion which followed Mr. CROLY directed attention to the value which he assigned to præcordial anxiety as a diagnostic symptom of ruptured bladder, a view which was not sustained by the facts of the case which Mr. Stokes recorded.

MICROSCOPIC DIAGNOSIS OF PHTHISIS.

Dr. PURSER exhibited the viscera of a man who had died of phthisis. In the lungs there were tracts of dense fibrous tissue surrounding the bronchial tubes and pulmonary vessels, and extending to the neighbouring portions of the pulmonary tissue. This was extensively consolidated by fibrous thickening of the alveoli. There were numerous tubercles which had for the most part undergone fibrous changes. Curation was not present to any great extent, but there was a large cavity due to this cause at the base of the right lung and smaller cavities at both apices. The bronchial glands were indurated and contained tubercle. Tubercles were abundant in the liver and spleen, both of which organs were amyloid. In this case the bacillus tuberculosis had been detected in the sputum five weeks before unequivocal signs of phthisis had been detected by the stethoscope.

Dr. FINNY said the patient in question when under his care was the subject of amyloid disease of the liver. The point of greatest interest on that part of the case was the evidence it afforded bearing on the view of Schupple and others as to where amyloid disease began. It was not amyloid degeneration springing from small arteries in the liver, and in which the whole enlargement was due to the liver cells being involved in the disease. Here the liver cells were pushed aside by the growing of the amyloid disease, the result of which was a sort of infiltration which caused atrophy and degeneration of the liver cells and the destruction of their functions.

Dr. WALTER SMITH said this was the first case published in Ireland in which a microscopical diagnosis of phthisis had been made, and that five weeks before the ordinary signs of the disease could be detected by a skilled ear. He did not know whether they could hold that the converse proposition was true, namely, that the absence of bacilli argued the absence of phthisis. A gentleman came under his care with evidence of an inter-thoracic tumour. The evidence of that disease subsided and the gentleman got well; but he got a cough, began to expectorate a quantity of purulent fluid, and got thinner, and it became evident that there was mischief at the right lung. He (Dr. Smith) forwarded some of his sputum to Dr. Purser, who, having examined it, informed him that he had been unable to detect any bacilli in it. That was several months ago, and the patient had not since developed any symptoms of phthisis.

The Section then adjourned.

EDINBURGH OBSTETRICAL SOCIETY.

FEBRUARY 14, 1883.

The President, Professor SIMPSON, in the chair.

Dr. HALLIDAY CROOM exhibited a

UTERUS REMOVED TWENTY-FOUR HOURS AFTER DEATH.

The case before death was diagnosed as one of hydatids. The patient died of phthisis and hæmorrhage from the uterus. On dividing the uterus a black mass was found, which Dr. Croom believed to be hydatids, but which he had not yet been able to examine; but as the uterus will be handed over to the Pathological Committee, the results of their investigations will be given to the Society at some future time.

Dr. Croom also, for Dr. Sinclair, exhibited a case of exomphalos.

Dr. REID (Glasgow) then read a description of, and exhibited

A NEW FORM OF BIVALVE SPECULUM.

After expressing disapproval of all other forms of specula, Dr. Reid stated that he had made several attempts to find something more suitable for his purpose. After several failures he had at last succeeded, and claimed the following advantages for the one exhibited:—Efficiency;

a good view of all parts permitted; does not interfere with cervix; easily used; suits all vaginæ; dilates all parts of vagina at will of operator; very portable; saves pain to the patient and time to the operator; and may be used in all positions of patient.

Dr. CROOM thought that the instrument might be very useful, but he now seldom used a speculum, as he thought that by the bi-manual method of examination a speculum was now seldom used, except for operations, and then he found Sim's speculum all that was needed.

Dr. PETER YOUNG thought that, as the speculum was in pieces, in practice one of the parts might be lost or mislaid.

Dr. BRUCE wanted to know if the walls of the vagina fell in between the valves.

Prof. SIMPSON did not quite agree with Dr. Croom as to being able to discard the use of the speculum, and he thought that the speculum exhibited for a bi-valve was likely to prove a most useful instrument. At the same time he suggested that the ends of the blades should be broader than those of the one exhibited.

Dr. BROCK (Glasgow) then read his paper

ON OBSTINATE VOMITING DURING PREGNANCY.

After mentioning the views as to the cause of this complication given by former writers, Dr. Brock gave a description of some cases he had attended, and stated that, as other observers had neglected an examination of the urine for albumen, he had carefully examined the urine in one case, a full account of which he gave. Every attempt to prevent vomiting in this case met with little success, the tincture of iodine, in 5-7 drop doses, and morphia, seeming alone to prevent the vomiting for a time, and he then decided to bring on premature labour, which he did, with immediate relief to the patient, the albuminous condition of the urine disappearing in a day or two. After some months the patient again became pregnant, and with symptoms like those before described, and again premature delivery relieved the patient. Dr. Brock, after challenging the opinions of other writers, suggested that the vomiting in pregnancy is not due to any condition of the uterus, but is probably due to some peculiarity on the part of the patient, probably of a neurotic origin, and this he maintained was, as a rule, the cause of persistent vomiting in pregnancy, and not the albuminuria, to which he had before drawn attention, and which he did not consider as primary, but as due to the neurotic affection, which was probably also the cause of the sickness. This view was supported by the following considerations: 1. Albuminuria in the non-pregnant state does not necessarily cause vomiting. 2. Albumen is frequently present in the urine in the pregnant state, and vomiting is not a more marked symptom in patients with albumen present than in those where the albumen is absent. 3. The ordinary sickness of pregnancy does take place without trace of albuminuria, and severe and fatal cases occur where the urine is free from albumen, if it may be inferred from reports of such cases being silent on the point that no albumen existed. It could scarcely be secondary, for the following reasons:—1. The albumen was totally absent on several occasions during the course of the illness, and entirely disappeared immediately on the cessation of vomiting—an occurrence which was unlikely to happen if the albuminuria in the first instance was caused by poisoning or impoverishment of the blood. 2. As stated before, severe cases, fatal from exhaustion, are reported where no allusion is made to the presence of albumen in the urine. 3. Albuminuria is frequently present in the pregnant state when there is no reason to believe there is the slightest poisoning or impoverishment of blood. 4. Obstinate and long-continued vomiting, at least in the non-pregnant state, does not necessarily produce albuminuria.

Dr. PETER YOUNG did not consider the explanation of the cause, as given by Dr. Brock, at all satisfactory, and maintained that all Dr. Brock suggested was that in some nervous females vomiting did occur—in fact, was a neurosis. He suggested that the ganglia at the cervix became excited during pregnancy, and may produce the vomiting by reflex action. He also recommended the use of the tincture of acenite in small doses, as proposed by Hodges.

Prof. SIMPSON congratulated Dr. Brock on the value of his paper. He did not clearly see the connection between persistent vomiting in pregnancy and albuminuria.

Dr. BROCK replied to the remarks of Dr. Young, and reiterated his opinion that the affection is purely of neurotic origin.

Prof. SIMPSON then read his paper on

THE PROPHYLAXIS OF OPHTHALMIA NEONATORUM, a disease more discussed on the Continent than in England. The disease has been suggested to be due to discharges from the vagina of the mother. Attempts to prevent it by washing out the vagina of the mother did not succeed; but the bathing of the eyes of the infant with a dilute solution of carbolic acid proved more successful. In Leipsic the use of a two per cent. solution of nitrate of silver to the eyes of the infants in the maternal hospitals was attended with a marked success. Prof. Simpson recommended that the eyes should be washed with water as soon as the head of the child is born, and a two per cent. solution of nitrate of silver dropped in soon after.

Dr. BRUCE stated that the affection of the eyes is rare in private practice.

Dr. CROOM used to syringe the vagina of all women in the Maternity, but without affecting the occurrence of the disease in the children. The cases in the Maternity Hospital are few and far between.

Dr. ROBERTSON suggested that it might result in face cases from the finger of the attendant entering the eye.

Dr. CRAIG expressed considerable anxiety as to the record of any case of face presentation with mechanical injury to the eye.

Dr. MILNE MURRAY and Dr. WILSON made some remarks on the subject, the former recommending in ophthalmia neonatorum due to gonorrhœa a solution of 75 gr. of nitrate of silver to the ounce.

Prof. SIMPSON briefly replied.

Germany.

[FROM OUR SPECIAL CORRESPONDENT.]

TREATMENT OF TYPHOID FEVER IN ZIEMSEN'S KLINIK.

—At the commencement of the disease, if there be constipation, calomel is usually given in doses varying from 0.5 to 1.5 grm. As soon as the temperature in the axilla passes 39.5° C. (103° F.), baths are employed, generally every two or three hours at the temperature of the room, about 15° R. (65° F.). The patient remains *sitting* in the bath about fifteen minutes, whilst the back, neck, and chest are being constantly bathed with the water, as in this manner the heat is extracted more gradually and the inspirations are rendered deeper. In some cases of already existing or threatened cardiac weakness the baths are omitted altogether, but only rarely, however; but the temperature of it is raised to 22° to 25° R. (81°—88° F.), and when the patient is in it is gradually reduced some degrees. Some alcohol is given both before and after each bath. If the baths fail to produce a decided effect on the temperature, antipyretics are administered. Rothe's mixture—which consists of acid carbolic and sp. vini ana, 1 grm.; tr. iodi, gtt. x.; tr. scimiti, grm. j.; aq., grm. 50; syr., 10 grm.; ol. menth, gtt. ij., M., and of which a teaspoonful is given hourly—has been extensively employed, but quinine still holds its ground. It is given, not too frequently, in full doses of 15 to 30 grs. every second day. If diarrhœa be profuse, it is checked by the use of starch enemata, to which have been added 20 m. of tinct. opii. This latter also serves the purpose of calming the patient, and thus rendering the attendance less laborious, and may be repeated several times in the course of twenty-four hours. The nourishment consists mostly of broths, with yolk of egg and milk. Wine is given from the commencement, the quantity and alcoholic strength mounting with the cardiac weakness. Stokes' mixture and freshly-pressed beef-juice are favourites in the height of the fever, or when collapse is threatened.

The diet remains unaltered until the eighth day after the subsidence of the pyrexia, after which easily-digested farinaceous and flesh foods are given; whilst the ordinary sick diet is not returned to until after the lapse of another week.

THE ACTION OF THE READILY SOLUBLE SALTS OF IODINE.—Dr. S. Kersch, of Prague, has for the last five or six years, (1875 to 1881) been conducting a careful inquiry into the action of the above named salts of iodine. Those experimented on were the ammonium, potassium, and sodium iodides. He verified their elimination from the system within an hour after administration. They also had a distinct sudorific and diuretic action. In connection with their sudorific action must be considered the occurrence of acne. This latter effect was greatest with the ammonium salt, and least with that of soda. The iodine introduced into the system is not all excreted within twenty-four hours. It may disappear from the urine and afterwards reappear, a peculiarity not noticed with any other substance, and important from a therapeutical point of view. The question here arises "where can the vanished iodine be secreted?" The author tested all the accessible secretions for iodine, but without result. The skin, hair, and nails, contained no iodine; but in the acne pustules it was demonstrable. The author does not decide whether in consequence of perspiration, sediments containing iodine, (and thus originating the pustules), are left behind or not. His conclusions as to the absence of iodine in the milk of nurses after administration of iodides agree with those of Stumpf and other writers. Being eliminated in the manner above described, it is easy to understand that it readily accumulates in the system, even if only small doses be administered, provided that it be given for a long time. Such a supersaturation has been observed after even small doses of ferric iodide. The author has observed in five cases that an acquired tolerance of iodides may be lost, so that the organism may easily acquire tolerance of any particular dose and as easily lose it. For this reason the mode of administering these salts is not unimportant. For instance, five grms. of iodide of potassium should not be dissolved in 200 grms. of water and a tablespoonful be given night and morning, but one dose of two to three grms. should be given at bed-time in a cup of tea. With the disappearance of the signs of super-saturation, a great part of the exudations will also be seen to disappear. The effect upon a person suffering from constitutional syphilis is magical if two grms. of potassic iodide be given, then a pause made until the signs of super-saturation have passed away, and if afterwards a similar large dose be given daily. According to the author the proper method of treating cases of chronic exudation of a syphilitic nature is to give the iodide of potassium, iodide of ammonium, or iodide of sodium in daily doses of from two to three grammes; when signs of super-saturation appear, to await the subsidence, and then to continue with similar large doses until either the affection has disappeared or super-saturation has again come on. In such a case no iodides of any kind should be given for a period of four days, as this is the earliest at which all the drug will have been eliminated. With weakly, uræmic, or scrofulous patients, small doses of iodide of iron may be given (0.05 to 0.10 grms. three times a day) but only until signs of super-saturation manifest themselves; after which four days' rest should be given, when the administration may be recommenced, and continued until the time when super-saturation may again be expected.

TWELFTH CONGRESS OF THE GERMAN SOCIETY FOR SURGERY.—The twelfth congress of the above Society will be held in Berlin from the 4th to the 7th of April next. The members will assemble for greeting on the evening of the 3rd, at 8 p.m., at the Hôtel du Nord (Unter den Linden, 35). Arrangements will be made for the reception of patients intended for demonstration at the Königl. Klinikum (Berlin N. Ziegelstrasse, 7-9), where, also, preparations, bandages, instruments, &c., may be sent. Letters may be sent up to March 15th to the President, B. v. Langenbeck, Wiesbaden, and after that date, to the Hôtel du Nord, as above.

The Services.

THE PRESENT AND FUTURE OF THE ARMY MEDICAL DEPARTMENT.

It is with no little hesitation that we proceed to notice a pamphlet having for its text the condition of the Army Medical Department, seeing that this Department has been so recently the subject of a Royal Warrant which has been universally admitted to be most liberal, and which, it was hoped, would have been for a long time conclusive. We are, however, compelled to concede a position to this publication, inasmuch as the contentions of the writer are based upon the words of a late War Office Committee, and supported by facts of simple arithmetic which cannot be set aside. In the report of the War Office Committee, 1878, it is said, page 50:—"Selection to be assured to such an extent that promotion to deputy surgeon-general be brought down to the age of 48," and at page 51, "The rank of brigade-surgeon would be reached on an average shortly after the completion of 22 years' service." These are the prospects distinctly held out as the result of the changes which they proposed. But what is the fact? That after the Warrant has been in operation for three years, the very easy process of dividing the vacancies from age, promotions, average voluntary retirements, and deaths, into the present total shows that "in five years time no surgeon-major can hope for even the step of brigade-surgeon in less than 28 years' full-pay service." To continue the calculation for the purpose of discovering the distant date of promotion to deputy surgeon-general would be useless. An error of six years in the earning period of a middle-aged man ought to be sufficient to claim reconsideration. It is, therefore, proposed to introduce the principle already in operation in the senior combatant ranks, and to retire all surgeon-generals and deputy surgeon-generals on the completion of seven years service in these combined ranks, or at the age of 60 years, whichever shall first occur. We are prepared to admit that this suggestion is a fair compromise, but we cannot at the same time shut our eyes to the fact that the late War Office Committee have been unfairly dealt with by those who have had to administer the Warrant which they recommended. The Committee relied largely on "promotion by selection" to bring about the results which they saw were desirable. As a matter of fact, "promotion by selection" has become a dead letter. If, therefore, those who are responsible for the carrying out of the Warrant do not like the odium of enforcing the clauses which alone can stimulate rivalry, and quicken promotion, those who serve under the Warrant must suffer the consequences; but to suppose that any Secretary of State will advise the Treasury to disburse more money for the purpose of preventing the unpleasantness of having to "promote by selection" is to have faith that would

remove mountains. If it is believed that the medical service works better by being composed mainly of plodding unambitious members, then by all means perpetuate the present system and the end will be permanently attained; but if there is any suspicion that the rivalry which brings the more industrious and more intellectual members of the profession into prominence in civil life would have the beneficial effect on the placid mediocrity of the Medical Department, then we think the duty of administering the Warrant in its entirety ought to be enforced. Should this pamphlet have the effect of calling official attention to the subject it will have answered a good end.

Special.

THE VACCINATION INQUIRY.

THE preliminary committee meeting was held last week in the Council Room, Exeter Hall, Dr. C. R. Drysdale in the chair. Mr. M. D. Makuna, in opening the proceedings of the meeting, stated that the object of the inquiry was to collect all available information on the subject of vaccination, collate it, and discuss it in conference meetings open to the members of the profession and those members of the public who are interested in the legislation of vaccination, which question would be discussed the last. It is admitted on all hands that the mortality from small-pox in this metropolis is increasing decade after decade, as we learn from the returns of the Registrar-General and the evidence of Dr. G. Buchanan, the Medical Officer of the Local Government Board, before the Hospital Commission. Further, the Anti-Vaccination Societies have been carrying on a systematic training of the general public in their belief by distributing millions of tracts and circulars, holding conference meetings and international congresses, and denouncing vaccination from platforms and in Parliament. Through their agitations, Leicester and Keighley have freed themselves from the operation of the Vaccination Acts, the prosecutions are becoming more numerous, and the bulk of the unvaccinated class is increasing. Under these circumstances, the inquiry is initiated, and through the expression of opinions in public meetings and publications of transactions all classes of people would learn the truths of vaccination, and the popular prejudice would subside. To meet with this object, 4,000 circular letters, with questions, were distributed among the medical profession. There are 350 members of the profession who have answered these up to this time. Eighty of these are public vaccinators and medical officers of health, and include the names of M.M. Pasteur, Chauveau, Drs. Braidwood, Klein, Renner, Wyld, Drysdale, Greene, Fleming, and others who have investigated the subject. Twenty-five have given their consent to act on the committee:—Drs. R. W. Batten, W. J. Collins, C. R. Drysdale, W. Easby, J. Greene, E. Gwynn, D. L. Haynes, R. W. Millican, R. Neale, A. Ransome, C. Renner, H. Tomkins, J. Trips, C. F. Willoughby, G. Wyld, G. E. Yarrow, E. Houghton, Pell, Braidwood, C. Swaby Smith, A. Cresswell Rich, T. E. P. Prideaux, B. Arcedeckne Duncan, Bernard O'Connor, G. Cordwint, and Charles E. Steele.

The Chairman remarked that the object of the inquiry was praiseworthy, and, through discussion of the subject, good results would be obtained. During the discussion meetings, all members of the profession who have originally investigated the subject should be invited, and it would be desirable to undertake original investigations. He considered that, as the public would be benefited by the movement, the Local Government Board and the public should be invited to cooperate and assist in the scheme.

In the discussion which followed, Drs. Dudfield, Yarrow, Swaby Smith, Houghton, Renner, Chairman, and M. Makuna took part. In answer to an inquiry, it was distinctly stated that the inquiry had no connection with any Anti-Vaccination Society, as had been suspected by Dr. Dudfield. It was to promote our knowledge of vaccination, and improve its practice. The present system of vaccination was a failure, especially when the mortality from small-pox was increasing in the metropolis, and any individual expression of opinion on the legal aspect of the question could carry

no weight with the profession and the public. The meeting was adjourned for one month to collect further information and collate it.

THE AMALGAMATION SCHEME OF THE HOSPITAL FOR WOMEN, LIVERPOOL.

As this subject is now uppermost in Liverpool, a word of explanation as to the origination of this institution may not be without interest.

The Liverpool Ladies' Charity and Lying-in Hospital were originally two separate institutions, of which the former was founded in the year 1796, and the latter in 1841. The Lying-in Hospital, about the year 1847, opened a dispensary for the treatment of diseases of women and children, and in the year 1855 a ward was opened for gynecological cases so-called. In the year 1868 the older Ladies' Charity, an exclusively maternity charity, amalgamated with the younger Lying-in Hospital, which since its foundation had undertaken the work of the treatment of diseases of women, and had thus practically become the Liverpool Lying-in Hospital and Hospital for Women. Had the Institution in Myrtle Street received its proper and full designation, viz., the Liverpool Lying-in Hospital and Hospital for Women, in all probability the need for the present movement would never have arisen; but unfortunately it did not. Some of the subscribers have, for some time past, looked with disfavour on the gynecological department, and when the late Committee of Amalgamated Charities proposed to use the whole of the hospital in Myrtle Street, which was built in 1861, for a Women's Hospital, and treat the labour cases at the patients' homes or in cottage hospitals, the scheme met with such vigorous opposition that it was defeated at several meetings of subscribers.

Being convinced of the impropriety of any longer carrying on the building in Myrtle Street as a Lying-in Hospital, and unable to convince the subscribers that their proposal was the best that could be offered, the Committee retired. This was in March of last year. A new Committee was appointed, pledged to carry on the Maternity Departments of the two charities.

About this time an independent movement was set on foot and vigorously prosecuted for the purpose of obtaining funds for carrying on the treatment of diseases of women, and when a considerable sum, about £1,000, had been raised, it was offered to the Committee of the Amalgamated Charities, on condition that they should administer it in accordance with the wishes of the donors. The Committee declined to accept it on these terms, whereupon the originators of the new movement proposed that, seeing that the treatment of diseases of women was an integral part of the charities, and that this department as such had a distinct and undeniable claim on them, they, the charities, should allocate a certain sum to the new movement on condition that they should take over and continue the working of the gynecological departments (in-door and out-door), of the charities.

After some discussion, the Ladies' Charity and Lying-in Hospital agreed to hand over to the new movement, now regularly constituted and called the Hospital for Women, Liverpool, the sum of £1,500 on the conditions named above. The President and Vice-President of the new hospital were respectively President and Secretary of the amalgamated charities before the resignation of the old committee. Three other members of the old committee are also on that of the new hospital.

It will be seen from the foregoing that the Women's Hospital is but an old charity under a new name, and that it does not multiply or add to the already existing charities, but merely takes the place of an old one threatened with extinction. The sum obtained up to the present is £3,750, including the £1,500 from the Ladies' Charity and Lying-in Hospital, which sum, however small and inadequate it may be, is very encouraging, considering the short period of time during which the proposal has been before the public, and considering the large sum—about £100,000—required for the rebuilding of the Royal Infirmary, and of which nearly £80,000 has already been raised.

A special general meeting of the governors and subscribers of the Hospital for Women was held last week (Feb. 12th), for the purpose of adopting the rules and bye-laws of the Hospital, and to elect the medical staff, Mr. T. A. Bushby

in the chair. The rules as proposed by the Committee were adopted, when, on the motion of the Chairman, seconded by Mr. Clayton, Drs. Burton, Imlach, and Lupton were appointed honorary medical officers, and Drs. Edis, Davies, and Steele were appointed assistant medical officers for the charity. Some conversation took place as to obtaining a suitable building for the purposes of the hospital, and the Secretary said he had found great difficulty in fixing upon a suitable place. The old Southern Hospital building had, however, been strongly recommended by Dr. Cameron. The funds now in hand amount to £3,750, but a sum of £10,000 is required to start on a secure basis.

Provision will be made in the new hospital for patients who are able to pay either fully or part of the cost of maintenance, as well as for those unable to contribute. The Countess of Sefton has, we understand, accepted the position of lady patroness of the institution.

WEDNESDAY, FEBRUARY 21, 1883.

THE MEDICAL STUDENTS' REGISTER.

THE issue so early in the year of the official list of students in medicine is eminently creditable to Mr. Miller, the Registrar of the General Medical Council, who has done much to improve its arrangement. In addition to the place of study of the student, three columns are now added, which contain—*a*. The date of passing a preliminary examination; *b*. The date of registration as a student; and *c*. The date of commencement of medical study. This additional information must prove valuable, because it at once shows whether or not the student has complied with the order of the Medical Council that he shall pass his preliminary examination and register himself not later

than fifteen days after his commencement of medical study. In Ireland this knowledge will be invaluable, because it will enable the Medical Council, or any one else who is interested in the inquiry to detect the existence of "March hares," as those students are denominated who are entered in certain Irish schools in the month of March for the courses of study which have been in progress since the previous November. Mr. Miller deserves our thanks for having afforded us the opportunity of checking this disgraceful practice, and we promise him to avail ourselves of the information placed at our disposal if necessity should arise for exposing the prevalence of the system in any particular school. The granting of certificates of "diligent" attendance to students who have not even been entered for study until the courses are nearly terminated is, however, nothing more objectionable than the selling of such certificates to those who are confined to offices and shops from 10 a.m. to 6.30 p.m., and as long as this latter transaction is permitted, it is hardly to be hoped that exposure will amend the "March hare" system.

The return of numbers of students who presented themselves at various preliminary examinations gives us the following figures in connection with the chief examining bodies of the kingdom:—

PRELIMINARY EXAMINATIONS.

<i>England.</i>			
Oxford Locals	24
" University Examinations	37
Cambridge Locals	63
" University Examinations	63
University of Durham	47
" " London	151
College of Surgeons	127
Apothecaries' Hall, London	122
College of Preceptors	159
<i>Scotland.</i>

" " Galway	7
" " Belfast	1
Intermediate Educational Board	5
<i>Foreign.</i>			
Calcutta	17
Melbourne	11
Sydney	16
Cape	14
All others	30

Amongst the examinations in general education which the General Medical Council regards as sufficient, we find those of the "American Scientific and Theological Institution of Somokoff" and the "Gymnasia of the Circuit of Dorpat." We think it well to remind students that these centres of preliminary examination (the educational standard of which has been, without doubt, carefully tested by the Executive Committee) are open to them,

and we have no doubt that a *testimonium* of learning from Timbuctoo will be accepted with equal readiness if tendered to the same critical tribunal. So much for preliminary examination.

As regards the places of study of registered students, the figures which we epitomise below are equally interesting. The number of first year's students entered at each school in the year 1882 was as follows:—

SCHOOL ENTRIES.

<i>London.</i>

Casbel and Cavan Infirmaries	2

A point worthy of notice in comparing the medico-educational systems of the three kingdoms is that, while in England 153 students were registered as "pupils with a registered practitioner," in Ireland only 16 were so registered, and in Scotland not one. Two theories to account for this fact may be suggested: either the apprenticeship to a general practitioner is considered of greater value in England than elsewhere, in view of the greater prevalence of this sort of practice in that country; or the unqualified assistant system brings to the profession a large number of students who call themselves pupils.

We hope we may assume that this pupilage is not used as a cover for an evasion of the fourth year of study required by the licensing bodies, but we confess to a suspicion that certificates of such pupilage are very readily attainable by any one who wishes to convert his three years of study into four.

We repeat our appreciation of the good service done by Mr. Miller in this as in other departments of the Medical Council business, and we are truly glad to find that at last the Medical Students' Register has been "invested with merit."

THE HUNTERIAN ORATION.

We are glad to be able to congratulate Mr. Spencer Wells on the happy judgment with which he has adopted the suggestions we made two years ago when commenting on the Hunterian Oration delivered in 1881 by Mr. Luther Holden. We ventured at that time to protest against the waste of opportunities afforded by these commemorative occasions to stimulate the progress of scientific medicine; and while admitting the appropriateness of periodical reference to the life and work of the great Hunter, we urged that the biennial address ought to be something very much more purposeful than a mere biographical memoir. So aptly has Mr. Spencer Wells appropriated the spirit of our complaint, that we would now modify the terms in which it was expressed, and predicate that the example set by the present President of the Royal College of Surgeons will powerfully influence the realisation of consequences which we had but dim hopes of when the following lines were written by us two years since:—"As it is, we venture to think the advantages to science are very limited in extent that follow from the Hunterian Oration, while the honour done to Hunter grows less and less with the lapse of every year permitted to pass without one effort to convert the festival day into one commemorative of renewed discovery as well as of retentive memory."

In one respect Mr. Wells has pursued a line to which every Hunterian orator stands committed by the terms of the call to which he responds—viz., with respect to recalling the names and achievements of those workers in the field of science who have passed to the great majority, in the intervals between the orations. The list of those thus honoured on Wednesday last is a heavy one, including no less than 368 associates of the College itself; while of scientific worthies not thus nearly related with it there were many, and Darwin of the number, who could not be omitted from the roll of the distinguished dead. To such length, indeed, did Mr. Spencer Wells deem himself compelled to refer to those who have "gone before," that the half of his address was obituary; and in place, then, of dwelling for the remainder of the time at his disposal on the one theme to which previous orators have given attention, he rather dilated on the advances made and possible to be made by the development of those principles for a knowledge of which the world is mainly indebted to John Hunter's untiring observations.

The prosecution of experimental research, and the harassing conditions imposed on students in this country, owing to the meddlesome ignorance of fussy-minded bigots, formed a fitting subject of discussion for one who has so often suffered from the persecution of fanatic and intolerant agitators as Mr. Wells himself. The probability of future advances by aid of combined research was also favourably reviewed by the lecturer; and the vast

additions to our knowledge made by Pasteur and others were the concluding themes of an address which will rank as one of the most useful and novel of all Hunterian Orations.

BUMBLEDOM AT THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

By a recent decision of the Royal College of Physicians of London, or of an executive officer of the College acting in its name, a most arbitrary and, in our opinion, unjustifiable impediment has been placed in the path of a Fellow of the College, whereby he is debarred from pursuing an extensive and beneficent practice. The gentleman referred to is a most distinguished member and past-president of the Medico-Psychological Association of Great Britain; author of innumerable researches, many of which possess the highest value; a doctor of medicine of long standing; and proprietor of a private asylum for the insane, in the conduct of which he has gained universal praise and respect, and where he has faithfully utilised the opportunities presented to him for advancing the scientific study of psychological medicine in every possible way. At the same time he enjoys the distinction conferred by the Fellowship of the Royal College of Physicians; and it is to this fact that must be attributed the fulmination of an edict commanding him henceforth to abstain from advertising the existence of his asylum. It might at first be supposed that the College had been scandalised by the appearance of announcements in lay newspapers, in which the sacred symbol "F.R.C.P." was held up to the vulgar gaze; but, on the contrary, the suppressed advertisement has never been inserted in any but strictly professional journals, and always, be it in justice added, to the great advantage of medical men themselves. Now, however, the College rules that such advertisement comes under the category of announcements tabooed by the re-affirmed regulation about which it so fussily excited itself a year ago; and in a spirit of obedience, as admirable as in one sense it is Quixotic, the offending Fellow has acquiesced in the demand made for the virtual voluntary annihilation of his own interests.

The occurrence is one which may well excite a passing criticism on the manner in which the College of Physicians is carrying out its efforts to purge the profession of objectionable practices; it is also calculated to evoke opinions the reverse of complimentary to the judgment which characterises many of its recent performances. It is difficult to regard this last instance of grandmotherly legislation as the outcome of lofty-spirited attempts at reform; it rather bears on the face of it evidence of littleness and pettiness, which should be altogether alien to the proceedings of a great and ancient corporation like the Royal College of Physicians. Hitherto, the pages of medical papers have always been regarded as fit and proper media for the dissemination of every kind of information useful or instructive for medical men to read; and it is certainly an entirely original rôle for a private society to play, when it presumes to dictate concerning what shall or shall not be

inserted in papers over which it can claim no shadow of right to exercise control. We ventured at the time when the discussion on advertising commenced to predicate what might possibly arise from the hysterical excitement indulged in by a section of the College Council; but we confess we are amused at the extent of the folly to which these erratic law-makers have descended. At no period of their intoxication could we have supposed they would be guilty of such outrageous absurdity of conduct as is shown by their attempts to "boycott" the medical press; and it is to be hoped that the period of reaction, of returning sense and consciousness of the ridiculous nature of their pretensions, may be speedy; and especially in the interests of a corporation which is fast becoming an object of contempt among men of any strength of mind, or with any capacity for judging motives.

Moreover, the College is without the justification of excuse for its conduct to be derived from its own by-laws; for the wildest inventor of regulations in the past never contemplated so nonsensical a prohibition as that referred to. It is too evident that any rational being would regard the privilege of fellowship of any college as dearly purchased at the expense of renouncing every legitimate right conferred by his professional status; and this is in substance what is now exacted from every purchaser of the highest diploma conferred by the London College of Physicians.

Public opinion, before which even the most powerful must eventually bow, will not be slow to insist on a right name being given to the erratic and erroneous policy by which the College has of late signalled its actions. The time is not far distant when an answer must be given to several pertinent questions; when it must be explained why it is permitted to some Fellows to indulge in the most promiscuous and wide-spread advertisement, while to others it is not given to use even the properly-recognised organs of professional opinion? Why rules which stretch to illimitable lengths in one direction are absolutely and rigidly fixed in another? and why spasmodic essays at improvement are not resigned in favour of wholesale and wholesome change in the general procedure of the College? For a long time it has enjoyed a reputation for staid respectability, and it might possibly be worth its while to encourage the popular belief in its pretensions to this character. To do so, however, it must be quick to remove more than one imputation, and to remodel a good many of its regulations in accordance with existing circumstances. Thus, for instance, it might, advantageously for itself and for medical education, expand the limits within which it is enabled to select examiners. It may not always be so fortunate as to have even one possible candidate more than it requires, as occurred at the last election. As it needs increase, the number of exceptionally-situated members of the College engaged in tuition may very well fall short of the vacancies arising; and it might even be suggested that at all times there may be found outside the prescribed circle men at least with claims as great, if not greater, than are possessed by those within it. Nor is this the only matter in connection with its examination

system on which the College of Physicians might with good result be questioned; and it would be well for it to consider, ere it promulgates any more of the foolish demands it has so much indulged in of late, whether a little of the spirit of self-inquiry would not better become it at the present time.

If there is really a desire on the part of the College to arrest the advertising of which it has complained, there is ample opportunity for it to distinguish itself by sacrificing not a few of its most prominent officials. Outsiders are scarcely likely to be afflicted with the convenient blindness that appears to have fallen on the College of late; and they, therefore, criticise the more strongly such paltry and wholly unworthy proceedings as this last attempt to arrest *legitimate* advertising. We thoroughly admire the spirit of high-minded respect for its requirements paid by the gentleman chiefly interested to the *ipse dixit* of his college; but, at the same time, we emphatically protest against the miserable spitefulness of the activity which has singled him out for persecution on utterly untenable grounds, when at the very same time other and glaring offenders are permitted to sin unrebuked.

Notes on Current Topics.

The Lethal Trace.

AN interesting study of the value of sphygmographic signs as indications of approaching dissolution is contributed in Dr. E. C. Seguin's *Archives of Medicine* by R. W. Amidon, M.D. In this essay the author supports the proposition that there does occur in acute disease a pulse which confirms the gravest prognosis, and which, when transferred to paper, may well be called the lethal trace. The article is enriched with a series of illustrative tracings, and as it includes a clear and intelligible demonstration of the causes which bring about the physical changes of altered pulsations, it cannot fail to serve a most useful purpose, whatever may be the conclusions arrived at. On the main contention, Dr. Amidon does not, however, insist that every pulse exhibiting rapid monocrotism is unerringly indicative of impending death, but that reaction is impossible in those cases where the arterial trunks lose the power of contractility, even with a strong heart; in other words, he includes other data than mere loss of arterial tension in his calculations, the results of which will not improbably be borne out by the experiences of a good many observers. The same number of the *Archives* contains several papers of unusual interest; among them is an elaborate and carefully prepared article on the small muscles of the hand, by Dr. Clovis Adam, which will be highly interesting to anatomists, and also to physiologists, its author making especial reference to the use of the various structures described. Dr. David Webster contributes a series of successful experiences with calcium sulphide employed for relieving diseases of the eye; and Dr. Isaac Ott concludes a paper on the physiological action of *Convallaria maialis*, by assuming that its action on the heart differs from that of digitalis in that it affects some other part of the organ than that influenced by the latter drug. It does not act in the cardio-inhibi-

tory centres, or on those alone, for whereas digitalis is powerless to increase arterial tension after section of the spinal cord, convallaria is still able to produce this effect under the same conditions.

Death of a Noted Lunatic.

THERE recently died in Broadmoor Criminal Asylum a lunatic whose name will be remembered in connection with a dastardly outrage on Her Majesty Queen Victoria, committed in one of the early years of her reign. Captain John Goode was afflicted with a form of monomania which compelled him to assert that he was the son of George IV. and Queen Caroline, and having pushed his madness to the limit of publicly insulting the Queen and threatening her in the streets in 1837, he was very properly tried for the offence and sentenced to lifelong confinement as a lunatic. The incident created very great excitement at the time, but the present generation is unfamiliar even with the name of the offender. His insanity was confined to this particular subject; on all other matters he is said to have been apparently rational and collected, and the case is one which, though by no means unique, is still surrounded with a certain amount of interest for psychological curiosity hunters.

"Hydrotherapy."

A NOTEWORTHY addition to the limited number of English hydropathic establishments was made last week by the public opening of the Hall, Bushey, as a "hydrotherapeutic" institution. In the way of architectural and luxurious surroundings, inmates of this new water sanitarium will enjoy most undoubted advantages, the appointments and fittings being thoroughly in keeping with the magnificent structure now first adapted to the purpose of its present proprietors. The "Hall" was formerly the residence of Mr. Marjoribanks, and being situated in a park of some 240 acres, is admirably fitted to serve as a pleasant temporary home for that class of sick persons on whom the curative influences of water can be brought to bear with advantage. Without lending anything to the beauty of the original building, an extensive series of baths of all descriptions has been added to one wing; but the usefulness of the outgrowth is beyond question, and it undoubtedly supplies in the most efficient way possible what after all is of infinitely greater importance to a hydropathic institution than mere external loveliness, viz., every balneopathic resource invented by the genius of modern improvers on the old principle of "wash and be clean." Chief among the arrangements is the Turkish bath, which is constructed with a view to the greatest possible comfort. Its compartments are separated by glass screens, and connected with it is a most inviting and capacious "plunge." It possesses the additional advantage of novelty in that the outlet is at the far side of the coldest compartment, respecting the superiority of which innovation, however, we shall be glad to have some further assurance. Room is provided in the Hall for one hundred visitors, and its easy distance from town, together with the beauty of its situation, and good management on the part of its proprietors, ought to ensure a remunerative degree of success for the venture. At the opening ceremony Sir

Andrew Lusk, M.P., proposed prosperity to the undertaking, and several other speeches, including one from the manager, Mr. MacDonald, were made, all descriptive and congratulatory as the occasion required. The resident medical officer is Dr. Sack, who is said to have made a special study of hydrotherapeutics.

Bequests to Medical Charities.

DURING the past few days several of the hospitals in London and the provinces have become possessed of considerable legacies; amongst these may be mentioned the munificent bequests of the late Mr. George Tierney of £5,000 each free of legacy duty to St. George's Hospital, Charing Cross Hospital, Westminster Hospital, Royal Seaman's Hospital, University College, Middlesex Hospital, and the Brompton Hospital for Consumption. In his will the testator desires that his good friend, Dr. Quain, should receive and enjoy any rights or privileges attaching from the several hospitals to the above legacies. The Liverpool hospitals also have come into possession of £2,000 under the will of the late Mr. George Green Hornby, of Liverpool, to be divided thus:—The Royal Infirmary, the Royal Southern Hospital, and the Northern Hospital receive £200 each; the Liverpool Medical Missionary Society, the Eye and Ear Infirmary, the General Hospital for Consumption and Diseases of the Chest, receive £100 each; and £200 is to be equally divided between the Liverpool South Dispensary, Liverpool East Dispensary, and Liverpool North Dispensary. A new hospital having been found necessary at Burnley, Miss Barnes, formerly of that town, has expressed her intention of giving £1,000 towards the new building, the fund for which now amounts to £6,000, in addition to the gift of the site.

Dr. Matthews Duncan's Lectures.

ON Friday last Dr. Matthews Duncan delivered the first of a series of three lectures at the Royal College of Physicians of London "On Sterility." The lecture, which was listened to by a crowded and distinguished audience of medical men, was chiefly devoted to a consideration of the influences bearing on the periods of child-bearing in married women, and was illustrated by a series of tables, which, together with the lecture, will be fully reported in our next issue.

A Strike against the Lady Students.

THE *Canada Medical Journal* reports a peculiar condition of affairs in the Royal College of Physicians and Surgeons of Kingston, Canada. That body has among its students seven ladies. The relationship between them and the male students seems to have been at least fairly cordial till a week or two ago, when the ladies took umbrage at something uttered in the class of Physiology, and in a body left the class room. Immediately the male students were up in arms, and insisted that females should not be taught with them. For a brief period the faculty were firm in resisting the demand. The male students were equally determined, and decided to leave the school in a body if their request was not granted. They telegraphed their situation to all the other medical schools in Canada, some of which offered favourable

terms. This brought the Faculty to a full realisation of their position, and the flank movement of the students was successful, the Faculty granting all they asked. In future male and female students will not study together in Kingston.

Extirpation of the Gall-Bladder for Chronic Gall Stones.

THIS operation has been successfully performed by Langenbuch, of Berlin, on the 15th of July, 1882, upon a man, æt. 43, the urgency of whose symptoms justified the risks of the operation. The details of the case were given in the *Berliner Klin. Wochenschrift*, November 27, up to which date the patient's health had steadily improved. Dr. Langenbuch regards this operation as a safe and justifiable one, since it is easy of performance, and the organ removed is not one the existence of which is necessary to life. The steps of the operation are fully described. He recommends it to be performed only by a practised surgical hand, and under the guarantee of the most rigid antiseptics. If very distended the gall-bladder may be aspirated, thus preventing the chances of rupture and escape of contents into the abdominal cavity.

Conviction of a Midwife.

A MIDWIFE who had infected a number of women with syphilis through attending labours while suffering from a chancre on one of her fingers, was last week found guilty, and sentenced to twelve months' imprisonment with hard labour. This conviction was mainly effected by the spirited action of Dr. Hime, who first brought the case beneath the notice of the law officers, and to whom the thanks of the profession are due for the manner in which he had exerted himself to obtain the punishment of a serious offender.

The Ready Method with a Bad Lecturer.

THE *Canada Medical Record* reports that the primary students of McGill Faculty of Medicine, at Montreal, have revived in a spirited way a grievance which almost every year for the past twenty-five years has come to the surface. They complain that the lectures given by the Professor of Materia Medica are not such as they require; that they are by far too minute, and that as they cannot find the matter in books they have to depend upon notes. These they cannot take, as the Professor lectures too fast. They have petitioned the Faculty, but this has been done before, and has never resulted in any improvement, because, if we understand the matter right, the Faculty are powerless to act. They intend also to petition the Governors of the University.

THE highest annual death-rates last week in the large towns, from diseases of the zymotic class were—From whooping-cough 1.6 in Leicester and in Preston, and 3.0 in Hull; from scarlet fever, 1.6 in Sheffield, and 2.1 in Leeds; and from fever, 1.4 in Blackburn, 2.6 in Sunderland, and 2.8 in Newcastle-upon-Tyne. The 37 deaths from diphtheria included 14 in London, 9 in Glasgow, 3 in Edinburgh, 2 in Nottingham, 2 in Liverpool, and 2 in Sheffield. Small-pox caused 2 deaths in London, 4 in Newcastle-upon-Tyne, and one in Sheffield.

Spina Bifida.

A COMMITTEE, consisting of Messrs. Howard Marsh, Pearce Gould, H. Clutton, and R. W. Parker, having been appointed by the Clinical Society of London to inquire into the results of the treatment of spina bifida by injection, a communication has been addressed to members of the profession in which the committee asks to be furnished with—1st. Reports of cases treated by this method. 2nd. Descriptions of any specimens of the deformity in possession of those the committee address. 3rd. Recent preparations, or any examples in still-born infants which the committee may be allowed to dissect. Such specimens will be carefully returned if desired; or if agreeable to the owner, presented to the Museum of the Royal College of Surgeons in his name. The committee will also be very glad, should the occasion offer, to be afforded the opportunity of examining any living examples of this deformity. Letters to be sent to Mr. R. W. Parker, 8 Old Cavendish Street, W.; and specimens, under cover, to Mr. F. S. Eve, Museum, Royal College of Surgeons, Lincoln's Inn Fields, W.C.

The Mechanical Excitement of the Peripheral Nerves in Tetanus.

MUSCULAR excitement following percussion of certain nerve trunks and muscular masses is observed irrespective of pathological conditions. But this phenomenon is always present in a very exaggerated form in tetanus, and is characteristic of this disease; but Prof. Schultz, who has recently given much attention to the subject, has noticed it in a minor degree in glioma of the spinal marrow, and by Erle in a case of paralysis of the bulb. It should not be confounded with the nervo-muscular hyper-excitability of Charcot, which is an appendage of hypnotism and which relates to contractions and not to clonic spasms. Here, in fact, there are veritable muscular contractions realised immediately upon mechanical excitement of the nerve trunk, such as a shock, percussion or traction of it. This muscular excitability forms an integral part of the disease to this extent, that it alone can exist before the appearance of an attack of tetanus, which declares itself upon a special cause, such as acute disease or wound.

In certain cases the compression of an arterial trunk gives the same result, doubtless by reason of the anæmia which it produces, for in one of Schultz's cases the elevation of the arm caused an attack. The author, therefore, naturally concludes that tetanus is an affection of the peripheral nerves; that mechanical muscular excitability is not of central origin: if, for example, we have to deal with an anterior poliomyelitis or a lateral sclerosis we do not observe the tetanic symptoms. The frequency of paresthesia indicates that the lesion is one of the mixed nerves; galvanisation of the limbs or of the cord gives no result in bad cases.

THE "Croonian Lectures" of the Royal College of Physicians of London will be delivered this year by Dr. J. E. Pollock, the subject being "Modern Theories and Treatment of Phthisis." February 28, March 2 and 7, are the dates fixed, at 5 o'clock. Members of the profession will be admitted on presentation of visiting cards.

A SPECIAL service, in aid of the funds of Westminster Hospital, will be held at Westminster Abbey on Tuesday, March 13, at 7 p.m., at which Gounod's oratorio, the "Redemption," will be performed. All applications for tickets should be made to the secretary, Westminster Hospital, S.W., by whom alone they will be issued, and to whom also contributions may be sent.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Derby 13, Cardiff 16, Huddersfield 17, Norwich 18, Brighton, Plymouth 20, Leicester, London, Wolverhampton 21, Bristol, Nottingham 22, Birmingham 23, Birkenhead, Leeds, Bolton, Halifax, Preston 24, Portsmouth, Hull 25, Sheffield, Sunderland, Salford Newcastle-on-Tyne, Edinburgh 26, Manchester 27, Blackburn, Oldham 29, Glasgow 30, Liverpool 33, Dublin 37.

Scotland.

FROM OUR NORTHERN CORRESPONDENTS.]

THE EXTRA-MURAL SCHOOL, EDINBURGH.—The meeting of this School, held last Thursday, to discuss the relations existing between it and the University, proved a perfect *fiasco*. Several of the speakers mildly admitted that the cat should be balled, but no one had the courage to offer to perform the necessary operation, and taken altogether, the result was a lamentable exhibition of childlike pusillanimity. It may be as well for those not versed in Edinburgh medical politics to state the points of contention between the extra-mural School and the University. The former maintain that there is only one medical school in Edinburgh, divided into two branches, of which the extra-mural School is the elder by nearly 200 years. This being the case, considerable irritation is felt at the over-reaching tendencies of the University, and its appropriation of all the donations given to the *Medical School*, due to the ignorance of the donors as to the true state of affairs. The extra-mural School therefore naturally claim that students taking out the classes of the extra-mural teachers should participate in the advantages offered by the medical bursaries. To the extra-mural School the renown of Edinburgh as a medical school is entirely due, for until the modern innovation of importing *talent* from London, all the celebrated names in the University were originally teachers outside the University, and had gained their reputation before they became professors. For this unjust state of affairs the Edinburgh colleges are entirely to blame, for they have persistently paid more attention to increasing their funds by the sales of their Fellowships and underselling of the English and Irish corporations in the price of their diplomas and the quality of their licentiates. As it is the corporations under University influence are notoriously supine, leaving the extra-mural School to fight an unequal battle. On the popular idea that an Edinburgh diploma means an Edinburgh medical education the corporations are content to do an ignoble trade in their diplomas. The dread expressed by some of the speakers at the meeting, that if any stir was made to put the extra-mural School on a fair basis, the University would withdraw their recognition of the extra-mural teachers shows the state of demoralisation into which the school has lapsed. We shall return to this subject in succeeding articles. As soon as the executive committee to inquire into the working of the

Scotch University system is appointed, we shall take the opportunity of pointing out the lines on which reform should be carried out.

THE PATERSON BURSARY AT THE COLLEGE OF SURGEONS, EDINBURGH.—Some two years ago Dr. Paterson presented the College of Surgeons of Edinburgh with £1,000, with which, with the consent of the donor, it was intended to provide a bursary to be competed for by students attending the extra-mural classes. A committee was formed to frame the necessary regulations for the competition, and a report of their labours has been anxiously looked for, but apparently in vain. Perhaps some member of the committee may be able to explain the painful silence as to the whereabouts of the Paterson bursary.

THE TERCENTENARY OF THE UNIVERSITY OF EDINBURGH.—We learn on good authority that the celebration of the tercentenary of the University is definitely fixed for the month of April, 1884. What form the celebration will take is not yet, we believe, decided, but hopes are entertained that it will be something befitting the renown of this, the youngest but most celebrated of the Scotch Universities.

GLASGOW TRAINING HOME FOR NURSES.—The eighth annual meeting of those interested in the Glasgow Training Home for Nurses was held on the 15th inst., in the Merchants' Hall, Glasgow. Mr. John Maclaren presided. Mr. Cuthbert, the secretary, read the annual report, which stated that at 31st December last there were 36 nurses attached to the Home, of whom 28 were fully qualified to go out to wait upon patients at their private residences, and 8 under training. During the past year three nurses left the Home after completing their terms of engagement, three got married, one died, and one was dismissed. Fifteen new applicants for training were taken on trial for longer or shorter periods, of whom twelve proved eligible, and were added to the staff. During the past year 156 patients were treated in the Home, of whom 102 underwent operations of more or less severity. The applications for nurses attached to the institution were more numerous than in any former year, and there would be no difficulty in finding full employment for a much larger staff than is at present available. During the year trained nurses were sent out to wait upon 250 cases of sickness in private families, and the best proof of the estimation in which the services of these nurses were held was to be found in the large increase of revenue derived from their fees. The income from nurses' fees during the year was £1,605 10s. 7d., which was £314 1s. 11d. over the previous year, and £885 2s. 8d. above the average of the eight years during which the institution had been in existence.

OPENING OF THE NEW HOSPITAL AT AYR.—The New Hospital at Ayr was formally opened on the 13th inst. by Mr. R. F. F. Campbell, of Craigie, M.P. It supersedes a small institution of the same kind which has been used during the last forty years chiefly for cases of infectious diseases. The new building is from designs by Mr. J. Murdoch, a well-known architect of the town, the cost being about £12,000, which has been almost entirely raised by public subscription. There are wards for the accommodation of about fifty patients, the furnishing of which has been generously undertaken by ladies and gentlemen in the locality, and the wards have in most cases been named after the donors. Convalescents have had suitable accommodation provided for them in such a manner as to enable them to enjoy the beautiful scenery that lies around the hospital. Of course due provision has also been made for the medical and nursing staff required in the

institution. Separated from the main building are wards for the treatment of fever and other infectious diseases. The accommodation thus provided will be sufficient for twenty-four patients. Another distinct block comprises the disinfecting-room, mortuary, &c.

THE SCOTTISH BRANCH OF THE PHARMACEUTICAL SOCIETY.—The fourth meeting of the present session of the North British Branch of this Society was held on the 15th inst., in the Society's Rooms, George Street, Edinburgh, under the presidency of Mr. Alexander Napier. The principal business was a paper "On the Methods for the Separation of Alkaloids," by Dr. Mathew Hay, Demonstrator of Materia Medica in the University of Edinburgh, who entered into the history of alkaloids, and showed how they could be separated from vegetable tissues containing them. He illustrated the remarks by experiments, and a discussion followed.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 10th inst., were at the rate of 30 per 1,000 per annum, against 30 in the preceding week, and 23, 33, and 35 in the corresponding periods of 1882, 1881, and 1880.

THE SPREAD OF TYPHUS IN GLASGOW.—Dr. Russell, in his usual fortnightly report on the health of the city, on the 12th inst., said:—"There are features of interest and importance about a group of typhus cases centering in the southern district which merit mention. On the 23rd December four cases of typhus fever were removed from an unticketed dirty house of two apartments on the south side. There are 18 cases of typhus, infecting five different houses, derived from one unreported case, of which at least 12 would not have arisen had the reception house been accepted when offered."

HEALTH OF EDINBURGH.—The mortality in Edinburgh during the week ending with Saturday, the 10th inst., rose from 81 to 114, and the death-rate was 26 per 1,000. Diseases of the chest accounted for 60 deaths, and zymotic causes for 5, of which 3 were due to fever, the intimations of this disease for the week being 7. No deaths from diphtheria, scarlatina, and measles were recorded.

Literature.

WHOOPIING-COUGH: ITS PATHOLOGY AND TREATMENT. (a)

In our opinion, the Fothergillian Gold Medal was worthily bestowed by the Medical Society of London on the careful and painstaking author of the above-named work. All reasonable credit is given to the researches of those who have in past years busied themselves with the pathology and treatment of whooping-cough, but we are taught that it is only lately that the true cause of this disease has been brought to light by Dr. Dolan in the theory that pertussis is a disease due in its origin to a bacillus, microbe, or protophytic fungus. "The very absence of any morbid change confirms me in my belief that whooping-cough should be classed amongst the group of diseases which have their origin in microbes or protophytic fungi"—p. 26. The author compares whooping-cough with hay fever, but it must be remembered that Blackley, in his researches into the causation of hay fever, has demonstrated the presence of the actual pollen granules that excite the paroxysm of catarrh; and proved, at the cost of some personal inconvenience and suffering, the power of these granules to set up the hay fever. With regard to whooping-cough, we have as yet little more than theory and conjecture to support the hypothesis of the germ theory of this disease. That such objections are likely to be raised to his theory the author is

fully aware, but with much sagacity he quotes the advice of Herschel, and shows how, for a time, a hypothesis may be very useful to work upon. When, in the present day, we hear so much that is of interest in connection with disease germs, bacilli, bacteria, and minute organisms as lying at the root of so many disorders, we think of the late Sir Henry Holland and chapter xxxi. of his "Medical Notes," in which he discusses the theory of animalcule life as a cause of disease. Sir Henry says that Kircher was one of the earliest propounders of the opinion, and that Linnæus gave his sanction to it. "Exanthemata viva," such as small-pox, measles, syphilis, whooping-cough, are all attributed to the agency of minute animalcules. Truly does Dr. Dolan say, quoting George Meredith, "that the moderns live on the ancients, and not one in ten can refer to the particular treasury from which he fishes." All honour and credit, nevertheless, to the clever men of the present day who, furnished with instruments of precision, have actually brought to view the bacillus anthracis and the bacillus of tubercle. Some day Dr. Dolan may show before an admiring Society the bacillus of pertussis. Sir Henry Holland and Linnæus had before their minds the theory, or hypothesis, of animalcule life as the germ of many diseases, and now we seem approaching practical demonstration of what was at first but the conjecture of observant and thinking minds.

The chapter on treatment bears evidence of great practical experience on the part of the author. We do not find much that is new, but we do find a very valuable appreciation of the remedies in ordinary use for the cure of pertussis. We fully agree with Dr. Dolan as to the use of prussic acid being hazardous, and of very little utility except in the vomiting of elderly children. Nitric acid is set down as "utterly worthless." The theory of the disease being of the zymotic class, unfortunately does not seem to have been made of much avail in treatment. "We may prevent," says Dolan; "we cannot act specifically on any zymotic disease; so the quinine treatment, in my opinion, has no scientific value." Clearly the author knows whooping-cough practically, and his observations on its prevention and treatment are well worth reading, while they leave us well satisfied with the carbonate of potash and cochineal mixture, which we have found, as yet, unsurpassed by any of the more modern remedies for whooping-cough.

A MANUAL OF GYNECOLOGY. (a)

If the medical student of to-day complains that the advances of medical science entail an amount of work unknown to his predecessor, he can at least solace himself with the knowledge that every attempt is made to render the facts with which he is expected to store his mind as easy of assimilation as possible. The increase in the number of books for the student in which some branch of medical knowledge is digested and tabulated so as to render the process of assimilation easy and expeditious, has of late years been very great, and the manufacture of these books shows no sign of abatement. The present volume is a good specimen of the class of which we have been speaking. It deals with a class of diseases of most frequent occurrence in general practice, and which no properly-educated medical practitioner should feel at a loss to treat. Yet, owing to neglect on the part of the student, and the want of a good manual treating on the subject, the diseases of women have gradually become the special preserves of a small body of specialists. An attempt was made a short time ago to supply the want just mentioned by Dr. Halliday Croom in his little work on "Minor Gynecological Operations," which rapidly went out of print, and of which the present book is its more ambitious imitator, at the same time going far beyond the other in its scope and in its treatment of the subject. The authors in their preface state that they have tried to keep before their eyes the great principle that the anatomy, physiology, and pathology of the pelvic organs form the foundation of good clinical work, and that as students feeling the want of a text-book based on this principle and embodying the most recent views from the various literatures instead of giving those of one school, they have in the volume now before us tried to supply the want they themselves felt. In this we think they are wise and

(a) "Whooping-cough: Its Pathology and Treatment." Prize Essay, to which the Medical Society of London awarded the Fothergillian Gold Medal for 1881. By Thomas M. Dolan, F.R.C.S. Ed., &c., &c. 1882. London: Baillière, Tindall, and Cox. Pp. 106.

(a) "A Manual of Gynecology." By Berry Hart, M.D., F.R.C.P.E., Lecturer on Midwifery and Diseases of Women, Extra-Mural Medical School, Edinburgh, and A. H. Barbour, M.A., M.B., Assistant to the Professor of Midwifery, University of Edinburgh. Edinburgh: MacLachlan and Stewart.

right, for although Edinburgh may claim a respectable reputation in this branch of medical knowledge, neither the general practitioner nor the student cares to be indoctrinated in the regular crotchets of any one teacher, however distinguished. Following the course suggested, the first part deals with the general anatomy, physiology, and methods of examination of the female pelvic organs. The anatomical and physiological portion is most fully illustrated by woodcuts of varying degrees of excellence—in fact, there is almost a redundancy of illustration throughout the book. The letterpress is full and clear, and there is no attempt on the part of the authors to shirk difficult questions. On the normal position of the uterus there appears to be considerable difference of opinion between anatomists and gynecologists, the former maintaining that the fundus of the uterus should be in the hollow of the sacrum, the latter that it should lie on the bladder. This difference of opinion suggests the question whether the fondness which some gynecologists evince for twisting the uterus about on all occasions on the point of the sound is altogether justifiable. Passing from these details, we come to several chapters devoted to the physical examination of the pelvic organs. These chapters are of considerable value, and detail step by step the various methods of examination. For instance, we are carefully informed "how to place the patient," "how to pass the speculum," "how to hold the speculum when passed," &c. Drawings of instruments of all sizes and shapes are given, not omitting the cervical scissors of one of the authors, the invention of forceps, we suppose, having at last come to an end. The second part deals with the diseases of the pelvic organs, and to the practitioner is by far the most useful portion of the book. Considerable care is, as a rule, taken to be clear and free from ambiguity, but the attempt has not always been quite successful, for we find on page 268 that a blister is recommended, but where it is to be applied no directions are given. The same page contains the following peculiar sentence: "Skill may often be shown in knowing to leave," &c. These are but slight blemishes, and where there is so much to praise it seems almost ungracious to notice them. We can heartily recommend this volume to the careful perusal of the practitioner and student. The value of the book is enhanced as a work of reference by the bibliographical record at the head of each chapter; in fact, the authors show an amount of honesty with regard to the sources of their information which might be followed with advantage by other writers.

Correspondence.

RHEUMATIC ENDOCARDITIS (THE LETTSOMIAN LECTURES).

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—To one or two points dealt with in Dr. Sansom's Lettsomian Lectures, published in the last few numbers of your journal, I would, with your leave, direct attention.

In speaking of rheumatic endocarditis, Dr. Sansom quotes and endorses the two practical reasons which I give for the failure of the salicyl compounds to control the cardiac as they do the arthritic inflammation:—First, that the cardiac mischief has generally commenced before the patient comes under observation; and, second, that rest, which is so essential to the recovery of an inflamed organ, and which is easily got in a joint, is unattainable in the heart. The first reason makes prevention impossible; the second is a bar to successful treatment.

But though this is true, it does not express the whole truth.

That a joint generally recovers from rheumatic inflammation, and that the heart does not, is a statement which expresses the broad results of clinical experience, but expresses them in a manner which, from a pathological point of view, is bald and misleading.

The truth is—and, striking as the statement may appear, it is absolutely correct—that *everything which recovers in a joint recovers also in the heart*. The one structure in the heart which does not recover—the endocardial lining—is also the one which has no analogue in any of the structures of a joint. In studying the pathology and treatment of rheumatic endocarditis, it is essential that this fact should be kept before us, for unless we keep it in view we are sure to fall into error. The parts which suffer in a joint in acute rheumatism are the fibrous ligaments and tendons, and the synovial

membrane; the parts which suffer in the heart are the fibrous rings and valves, the endo- and pericardial linings, and occasionally the muscular substance.

The fibrous structure of the rings and valves is similar in nature and function to the fibrous structures of a joint. Each is apt to be the seat of rheumatic inflammation, and in each this inflammation is generally recovered from.

The pericardium finds its analogue in the synovial membrane. Each is a very vascular membrane, each secretes a lubricating fluid, and each has for its function the facilitating the movements of a solid body. Each, too, is apt to be the seat of rheumatic inflammation; in each the inflammatory process tends to spread; and in both the tendency is to recovery.

The endocardium has no analogue in a joint. There is nothing in a joint which bears the least resemblance to it, either anatomical or physiological. It is a non-vascular membrane, in which inflammation cannot, and, as a matter of fact, does not spread. In structure, in nature, and in function it is identical with the living membrane of the blood-vessels with which it is structurally continuous.

When it is affected in acute rheumatism, there is no general inflammation of its surface, such as is found in the pericardium and synovial membranes. The mischief is limited to a small portion of one surface of the affected valve. I have elsewhere (a) shown that the occurrence of the lymph deposit which constitutes the endocardial change in acute rheumatism, and its limitation to one particular portion and surface of the valve, are to be explained, not by the direct action of the rheumatic poison on the endocardial lining, but by the mechanical rubbing against each other of valvular segments whose deeper-seated fibrous structures are the seat of rheumatic inflammation and thickening. This thickening of their fibrous structure it is which makes the valves rub, and the rubbing it is which irritates and roughens the membrane which covers them externally. The inflammation and thickening of the fibrous structure may be recovered from. What is not recovered from is the roughening of, and lymph deposit on, its non-vascular endocardial covering. This is not recovered from because the continued action of the valve keeps up the rubbing and mechanical irritation, and because the want of blood-vessels in the endocardium prevents absorption. This is a condition over which no drug could possibly exercise any control. It is directly of mechanical, and only indirectly of rheumatic origin.

But it is by no means certain that we may not in some cases, by the early and free administration of the salicyl compounds, prevent the inflammation and consequent thickening of the fibrous textures of the valve which is the origin of all the mischief. If we see a case early, and give these compounds freely, we may prevent the heart from suffering, as we undoubtedly do prevent joints from suffering. In no given case can we be sure of having got this result, for the absence of heart mischief can never be demonstrated to be due to the treatment. The possibility of such a result, however, is worth striving for, especially as the means of attaining it are also those called for in the interest of the joints. What is wanted is the speedy arrest of the rheumatic process. This object can be attained only by giving salicin or salicylate of soda in large and frequently-repeated doses.

This leads one to remark that my recommendations on this point have not been acted up to. Why, I cannot say, for I have pressed the point over and over again. My recommendation is that 20 to 80, or even 40 grains should be given *every hour* for six hours, or until pain is relieved (which it generally is within that time). That the same dose should then be given *every two hours*, till the pain is gone, and the temperature at or near the normal (which is generally the case within twenty-four hours). After that the same dose is given at widening intervals of three, four, and six hours for ten or twelve days.

But, instead of giving it thus freely and largely, most observers are content to give 15 to 20 grains every three or four hours. That is not nearly enough for the full curative effects of the drug, and I would again, through your pages, urge the giving of the dose which I recommend.

I do not exceed my right in asking that my treatment should be carried out in all its details, before its results are subjected to criticism.

Salicin is the preparation to which I give preference—not because I regard it as superior to salicylate of soda as an

(a) "On Rheumatism: Its Nature, its Pathology, and its Successful Treatment." By T. J. MacLagan, M.D. Pickering and Co. 1881.

anti-rheumatic—but because it may be given in large and frequent doses without causing such disturbance of the system as not unfrequently follows the use of the salicylate, and necessitates its suspension.

My experience too is that those treated by salicin (which is a bitter tonic), convalesce more rapidly than those treated by the salicylate.

There is an impression abroad that it is very expensive. It is not so. Two of the chief English manufacturers of it have told me that they are prepared to supply it to hospitals and dispensaries at ten shillings and sixpence a pound. Convalescence is so much more rapid under its use that I am not sure that it would not in the long run prove cheaper than salicylate of soda. But whichever is employed let it be given in large and frequent dose. I make this appeal in the interest of the heart as well as of the joints. Let every case of acute rheumatism be regarded and treated as one in which heart complications may be prevented, and it is probable that in some cases they will be prevented, but every hour is of importance. It needs no argument to show that the danger to the heart is less in a case in which the course of the disease is arrested within twenty-four hours than it is in one in which three or four days are expended in the process.

The fact has never been accepted by the profession that the course of acute rheumatism may in many cases be arrested within twenty-four hours of the time that treatment commences. The recognition of that fact (for fact it is) is the keystone to all possible success in the prevention of heart complications.

Your obedient servant,

J. J. MACLAGAN, M.D.

9 Cadogan Place, London, Feb. 15th.

MEDICAL REFORM.

THE view of the profession in Dublin respecting the coming Medical Bill has been strikingly and unexpectedly manifested within the last three weeks, and a long step has been taken towards a definite Irish medical reform policy.

The annual meeting of the Dublin Branch of the British Medical Association was fixed, and, in anticipation, a letter had been addressed by the Chairman of the Medical Reform Committee, asking for the co-operation of the Branch in support of a Bill based upon the Report of the Royal Commission which sat last session. That Commission, it will be recollected, had recommended a reform on the following lines:—

(a) That in future no practitioner shall be registered until he has passed a Central Examining Board—three such Boards being formed for England, Ireland, and Scotland, respectively, by the co-operation of the licensing bodies therein.

(b) That the educational requirements and examination of these Boards shall be identical throughout the kingdom.

(c) That licensing bodies shall confer no *qualifying* diploma, but shall continue to grant, on their own terms, the higher degrees to those who have already passed the Board.

(d) That the Medical Council shall be reconstructed, direct representation being given therein to the medical practitioners.

This policy has been steadily advocated by the Association for fifteen years, has been confirmed by repeated votes of the members, has been approved on a plebiscite of the profession by a majority of nearly 20 to 1, has formed the basis of Government Bills introduced by Lord Ripon in 1870, and the Duke of Richmond in 1879, and of private bills introduced each session for many years past by the Association and others. It is also the policy of the Irish Medical Association, discussed and confirmed at every general meeting for several years.

The request of the Medical Reform Committee for co-

operation being brought before the Branch Council, the whole subject was remitted to a sub-committee of five, who, after deliberation, brought up a report violently hostile to the proposed method of reform. They considered the proposal "inefficient as a measure of reform, and injurious to the profession and the public welfare," and that "it would be a positive advantage to preserve a number of different examinations and different courses," and furthermore, that "the formation of a single portal for entering the profession for each division of the kingdom . . . and a uniform standard of examination would . . . be difficult of accomplishment, destructive of the corporations, and injurious to the profession as well as to the public."

In lieu of the proposed reform, the only changes which the sub-committee proposed were—*a.* That the Medical Council should be given increased powers; *b.* That "no person should be admitted to the Register who has not passed . . . in medicine, surgery, or (*sic*) midwifery;" *c.* That "the false assumption of medical titles should be made an indictable offence to be punished by the easiest and simplest process of law."

This report of the sub-committee was stoutly resisted by influential members of the Branch Council, and certain parts of it, we hear, passed by a majority of one. It was, however, eventually adopted, and a paragraph inserted in the report recommending the Branch to decline co-operation with the parent Association. On the bringing up of this report an amendment was moved by Dr. Atthill, and seconded by the Registrar-General, to send this paragraph to the incoming Council for reconsideration, it being recommended to them to join in promoting a bill on the *principles* of the Royal Commissioners' Report. This amendment was debated for three adjournments, and was eventually carried by an apparent majority of about three to one, the vote being followed by the resignation of five of the anti-reform members of the Council.

We attach great importance to the decision, firstly, because it was not the hasty verdict of a few, but the well-considered pronouncement of a meeting which included most of the leaders of medical opinion in Dublin; and secondly, because the declaration of opinion emanated from a body of men, most of them teachers, and many of them closely interested in maintaining the *status quo* against all reform. We believe we are entitled to say that, if the same issue could have been put in the same way to a body of voters representing in due proportion provincial as well as metropolitan practitioners, the majority would have been ten to one instead of the proportion at which it stood.

It is neither necessary nor possible for us to enter upon a discussion of the propriety of direct representation, conjoint examination, and suppression of quackery. Upon these canons of medical reform there is really no serious difference of opinion in either England or Ireland.

As to the policy of reconstructing the General Medical Council by introducing direct representatives of the practitioners, no one seems to have any hesitation save the members of the Medical Council and the members of the Branch Sub-Committee. Fifteen years ago it was discussed in the British Medical Association in Dublin, and approved with only two dissentients. At Newcastle, in 1870, it was carried by an enormous majority against the united

efforts of five members of the Medical Council. In 1878, a plebiscite of the profession voted for it—Ayes, 5,075 ; Noes, 121—and at every meeting of the Association, and in every Bill promoted by it, the demand has been a salient feature. Of the eleven Royal Commissioners, two alone—the two members of the Medical Council—objected to the proposal, and of the witnesses, more than three-fourths gave evidence in its favour. The Sub-Committee of the Dublin Branch, though they did not actually condemn direct representation, discredited it, and included it in the general disapproval with which the Branch was recommended to stigmatize the policy of the parent Association.

The hostility of the Sub-Committee was, however, chiefly to the proposal to institute Central Examining Boards, which they based on two grounds—(a) “that it is a positive advantage to preserve a number of different examinations and different courses ;” and (b) that such proposal would be destructive of the licensing corporations.

As regards the first of these reasons, the Reform party maintained that “different examinations and different courses” had been heretofore productive of disastrous results to the public and the profession. It had, through the agency of competing licensing bodies, let loose upon society practitioners notoriously incompetent for their functions, degraded the profession in the social scale, made it impossible for those teaching and licensing bodies which desire to do so to maintain a reasonably high standard of medical education, and had greatly injured the immediate interests of the better class of such bodies. In illustration they referred to effect of such system in diverting from Irish examining bodies a very large proportion of the students.

We cannot, however, fail to recognise in the opposition of the Sub-Committee to reform a strong desire to maintain against all comers what they—most erroneously, as we think—fancied to be the interests of the licensing corporations. They urged that central examination will be destructive of the Irish colleges—(a) because it will probably involve a considerable diminution of the diploma fees ; (b) because practitioners, having obtained the right to practise through the central board, will not care to seek higher qualifications from the Colleges. Now on this point the Colleges themselves may be considered the best judges, and they have already, in spite of these objections, twice declared their readiness to accept a system which is in most important particulars the same as that now declared to be inadmissible. In 1873 the present Irish licensing bodies agreed upon a scheme identical in principle with that now proposed. A central board was then formed of delegates from the various bodies, and was to hold examinations, through which every student desiring an Irish qualification must pass. The conjoint diploma fee was to be (as is now proposed) reduced from its present amount, £42, to £31 10s. That scheme received the sanction of all the licensing bodies co-operating, and the *imprimatur* of the General Medical Council.

But the strongest argument of the Reform party in favour of central examination was based upon a comparison of the advantages to Irish Colleges of *compulsory* as distinguished from the *voluntary* combination of exami-

nations, for the latter of which the anti-reformers professed themselves eager. This argument was put as follows :—

If central examination be made compulsory, all licensing bodies must join in it ; whereas, in the case of voluntary conjoint examination, any licensing body may refuse to co-operate, and continue to grant its diplomas on any terms it pleases. Thus a voluntary system can never obviate the severe downward competition to which Irish Colleges are at present subject. Those Colleges cannot, without ruinous loss, reduce their conjoint diploma fee from £42 to £21—the fee for the Scotch double diploma—nor cut down their curriculum or make their examinations as easy as those of the Scotch bodies.

It has been fully proved that about *one-fourth* of the *entire body of Irish students* go to Scotland for their diplomas, and this exodus represents a loss of many thousands a year to the Irish Colleges and Irish teachers.

But under the proposed reform no such loss will occur. Students will, by leaving Ireland, gain neither in shortness or cheapness of study, nor in facility of passing, because the curriculum and examination will be, as nearly as possible, uniform. It may, therefore, be reasonably assumed that the large number of licentiates who are now lost to Irish licensing bodies will take their qualification where they have been educated. Thus, by compulsory conjoint examination, the Colleges will be in great measure recouped for the loss sustained by reduction of fee ; whereas, under *voluntary* reform, they admittedly stand to lose about *one-fourth* of their incomes.

We shall not further pursue the argument from the Irish point of view, which is outside the public aspect from which the House of Commons will view the question. We must, however, refer to one argument upon which the anti-reformers laid great stress. The Sub-Committee says—“It is proposed that the standard (of central examination) should be uniform, and it is admitted it must be low.” And again—“If too high a standard be adopted the supply of practitioners will fall short of the demand ; if so high as to prevent a supply of registered practitioners, unqualified persons will come forward to supply the demand.” Of these two statements the first is untrue, and the second illogical. It is *not* admitted that the examination standard must be low, nor have we ever heard of fact or argument to support such a hypothesis, which is simply a bogie got up to frighten educationalists, and, as to the difficulty of finding a mean between too high and too low a standard, we suggest to the Sub-Committee that it may be found at *competency*. The State has no right to ask more from medical practitioners, and certainly no moral right to accept less. It is a standard easily attainable, and, in fact, already attained by many licensing bodies ; and we can, we believe, trust a reformed Medical Council to strike the happy medium which the Sub-Committee has failed to find.

It will be observed that the Sub-Committee has taken a line of its own, but our readers will experience less surprise at this when they have read the following extract from the official address of the last President of the Branch, to whom, it is understood, the Sub-Committee is chiefly indebted for its policy :—

“The practice of medicine is open to all. Let us, too, give up the idea of protection. So long as we know and attend to our business, we need not fear the rivalry of any quacks. Let Colleges and Universities cease to claim for their degrees, diplomas, or licences, any privileges. Let that which is actually the case be openly avowed. Let the public learn that no licence is necessary to enable any man to practise medicine. Thus, and thus only, will degrees and diplomas in medicine rise to the rank of degrees in Arts.”

The Hunterian Society.—At the annual general meeting of this Society, held on the 14th inst., the following officers were elected for the ensuing year: *President*—*Walter Rivington, M.S., F.R.C.S. *Vice-Presidents*—Waren Tay, F.R.C.S.; M. Brownfield, L.R.C.P.; *A. L. Galabin, M.D.; *R. Clement Lucas, M.B., F.R.C.S. *Treasurer*—H. I. Fotherby, M.D. *Librarian*—P. L. Burchell, M.B. *Orator*—*George Roper, M.D. *Secretaries*—G. E. Herman, M.B.; *Charters J. Symonds, M.D. *Council*—Drs. *J. Hughlings Jackson, W. Talbot King, Stephen Mackenzie, H. Port, *J. McCarthy, *F. C. Turner; and Messrs. *E. M. Corner, E. Dukes, *T. R. Fenwick, E. G. Gilbert, G. J. B. Stevens, and *W. C. Toulmin. [Those marked with an asterisk did not hold the same office during the past session.]

Notices to Correspondents.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

DR. MATTHEWS DUNCAN will please receive our best thanks.

DR. J. K. E.—There is no law preventing a man calling himself Dr., unless it can be proved that he has assumed the title for the purposes of obtaining money under false pretences.

ARMY SURGEON.—We believe the only medical journal published in India is the *Indian Medical Gazette*, published monthly at Calcutta, under the editorship of Dr. K. McLeod. The work is ably carried on, but is not supported as its merits deserve, owing to the transitory position of Indian medical officers.

SIR JAMES PAGET.

THE following characteristic story of Sir James Paget is told by a correspondent in the last number of the *Students' Journal and Hospital Gazette*:—

"Sir James has a country house in Kent. A few days ago, as he was out walking, he witnessed a serious accident. Two men were driving in a cart, when one of them fell out, and the wheel passing over him, broke his leg. Sir James, with a kindness which belongs to his nature, had the man lifted into the cart, and proceeded to do what was required to be done. In the meantime the poor sufferer's companion hurried off to the local practitioner, whom he addressed in this fashion: 'Please, Sir, Bill has been and fallen out of the cart and got his leg broke; there's an old cove a-pulling of him about, but I can see he ain't up to much, so I wants you to come at once, sir, 'cos Bill's very bad.' The doctor hastened to the scene, and discovered at once, to his surprise, that the 'old cove' was Sir James Paget, who in the interim had improvised some splints and bound up the leg with a copy of the *Times* newspaper."

ANTRUM.—Any ordinary text-book of anatomy will yield the required information. For the surgical proceedings necessitated under the several conditions named, consult Gant's "Science and Art of Surgery," or other standard authority.

THE "HOMOEOPATHIC DIRECTORY" FOR 1888.

DR. HORACE DOBELL, of Bournemouth (formerly of Harley Street, London), requests us to point out that the insertion of his name among homoeopathic practitioners in the above Directory is both an injurious calumny and a piece of gross ignorance of his professional status, for which there is not the shadow of foundation. We hope the ranks of Hahnemann are not similarly swelled, or the proprietors of the Directory in question may find themselves the subjects of more libels than one.

MR. M. D. M. (Poplar).—The proposition will be considered at the next weekly meeting.

DR. B. (Glasgow).—Translation received with thanks. Proof will be sent you before insertion.

MR. DYSON should have asked the question of one of the pharmaceutical journals, as it hardly comes within our province to give instructions in compounding. However, the following may suit his purpose in the preparation of an impermeable plaster:—Mix enough collodion with castor-oil to render it elastic when dry, the oil having previously been rubbed with some zinc oxide. Into this mixture dip glass plates, and, after drying, redip and redry two or three times, or until a film of suitable thickness is obtained. Upon this paint the usual solution of isinglass to give it adhesiveness, and, after again drying, separate it from the glass.

MR. WELLSTAD.—The invention was decidedly a meritorious one, and has served a useful purpose for many years. It is, however, now superseded by modern improvements, of which there are several.

PHOTOGRAPH OF AN EXPLOSION.—An ingenious American has recently photographed the different phases of the destruction of a ship by a submarine explosion of dynamite. The result, says the *Scientific American*, was very interesting. There were five exposures made, and the time of each was chronocled by an electric chronograph. One photograph taken 1/10th of a second after the explosion showed the vessel broken up and a column of water 70 feet high. A second and a-half after, and the water had risen to 160 feet. A third photograph showed the column at its maximum—180 feet, and the fragments of the ship in the air. A fourth, taken 3.3 seconds afterwards, showed the whole mass falling again. And when the fifth exposure was made, the whole scene was as before the explosion.

AN INDIGNANT READER.—The case of "Dr." Jones, who was struck off the Register on account of infamous conduct, is an instance of the

feebleness of the law to put down wrong-doers. We hear his "practice" is greater than ever. We cannot advise you on the legal point. For the rest see reply to Dr. J. K. E.

SCARLET RUMOR.—Fee may be recovered from issuer if he negligently issues a ticket to an improper recipient, or from recipient if he obtained same by false representation. In either case ticket must be first cancelled. If you write exact particulars to Editor in confidence, further advice will be given.

DR. WILLIAMS.—The book in question is an excellent specimen of what a text-book for students should be—every subject tersely and concisely put, without partaking of the nature of a cram. Your son will doubtless confirm our opinion if the work be given him as an aid to his studies.

PASS LISTS are unavoidably held over until our next number.

MEETINGS OF THE SOCIETIES.

CLINICAL SOCIETY OF LONDON.—Friday, Feb. 24rd, at 8.30 p.m., Dr. Broadbent, On a Case of Supposed Hydrophobia treated by Chloral, with Recovery.—Dr. J. E. Fowler, On Two Cases of Pseudo-Hypertrophic Paralysis in Adults.—Mr. B. J. Godlee, On a Case of Fracture of the Radius and Dislocation forwards of the Ulna at the Wrist, in which the lower end of the latter bone was removed to effect reduction.—Dr. Pearson and Dr. Broadbent, On a Case of Acute Necrosis of the Right Orbital Plate of the Frontal Bone, giving rise to Thrombosis in the frontal end of the Longitudinal Sinus, in the Cavernous Sinus and Ophthalmic Vein.—Dr. Fowler will exhibit a Case of Occlusion of the Superior Vena Cava.

Vacancies.

Borough of Blackpool.—Medical Officer of Health. Salary, £150. Applications to be sent to the Town Clerk not later than Feb. 27th.
Borough of Cork.—City Analyst. Applications to be sent to the Town Clerk not later than March 6th. (See Advt.)
Donegal Union, Leaghey Dispensary.—Medical Officer. Salary, £100, and £20 as Medical Officer of Health. Election, March 1st.
Dunfanaghy Union, Crossroads Dispensary.—Medical Officer. Salary, £110. Election, March 7th.
Kent and Canterbury Hospital.—House Surgeon. Salary, £20, rising to £100 after twelve months' service, with board and lodging. Applications to be forwarded to the Secretary not later than March 23rd.
University College, London.—Dental Surgeon and Lecturer on Dental Surgery. Applications to the Secretary before Feb. 23rd. (See Advt.)

Appointments.

BURTON, J. E., L.F.P.S. Glas., M.R.C.S., L.R.C.P., Honorary Medical Officer to the Hospital for Women, Liverpool.
COPNER, A. J., M.R.C.S., L.R.C.P.E., House Surgeon to the Richmond Hospital, Surrey.
DAVIES, E. T., M.D., C.M., Honorary Assistant Medical Officer to the Hospital for Women, Liverpool.
EDIS, J. B., M.R.C.S., L.R.C.P., Honorary Assistant Medical Officer to the Hospital for Women, Liverpool.
GRIMSHALL, T. F., M.R.C.S., L.R.C.P. Ed., Consulting Surgeon to the Hospital for Women, Liverpool.
IMLACH, F., M.D. Edin., M.R.C.S., Honorary Medical Officer to the Hospital for Women, Liverpool.
LUFFON, E. J., M.B., M.S. Aberd., M.R.C.S., L.R.C.P., Honorary Medical Officer to the Hospital for Women, Liverpool.
MACDONALD, J., M.D. Edin., Medical Officer for the Walton District of the Chertsey Union.
STEEL, C. E., M.R.C.S., Honorary Assistant Medical Officer to the Hospital for Women, Liverpool.
THOMPSON, S. M., Medical Officer to the South Dublin Union Work-house.
VOSS, F. H. V., M.R.C.S., House Surgeon to the London Hospital.
WILSON, D., M.D., M.Ch. Q.U.I., Medical Officer for the Farnbridge District of the Kingston Union.

Births.

ELLIS.—Feb. 14th, at 7 Howard Square, Eastbourne, the wife of Heber D. Ellis, M.D., of a son.
MARTIN.—Feb. 9th, at 69 Harcourt Street, Dublin, the wife of Wm. J. Martin, M.D., of a son.

Marriages.

RIDLEY—WALKER.—Feb. 14th, at St. Stephen's Church, Dublin, George Pelrose Ridley, L.R.C.S.I., to Clemena Josephine, daughter of the late James Walker, Esq.

Deaths.

BUCHANAN.—Feb. 9th, at 28 St. George's Road, Glasgow, James Buchanan, M.D.
DEMPSTER.—Feb. 15th, at Cotham, Bristol, Surgeon-Major T. Erskine Dempster, late Bengal Army.
GILL.—Feb. 12th, at Bootham, York, Henry Clifford Gill, M.R.C.S., Medical Superintendent of the York Lunatic Asylum, aged 52.
HUNTER.—Feb. 15th, at 8 Eglinton Park, Kingstown, Margaret Allen, eldest daughter of the late James Hunter, M.D., F.R.C.S.I., of Bryansford, aged 50.
M'KIERNAN.—Feb. 10th, at his residence, Banagher, John Bernard M'Kiernan, Esq., aged 81.
TYNDALL.—Feb. 15th, at 277 Cornwall Road, London, W., Edward Tyndale, M.R.C.S., aged 78.
WILLIAMS.—Feb. 11th, at Birmingham, T. Watkin Williams, F.R.C.S., aged 66.

The Gulstonian Lectures

ON

STERILITY IN WOMAN.

Delivered in the Royal College of Physicians, London, February, 1883.

By J. MATTHEWS DUNCAN, M.D., F.R.C.P.L.,
Physician-Accoucheur and Lecturer on Midwifery at St. Bartholomew's Hospital, &c.

LECTURE I.—PART I.

ITS NATURE AND AMOUNT.

MR. PRESIDENT, VICE-PRESIDENT, AND GENTLEMEN,—Sterility is generally considered to imply the condition of a woman who, under ordinary favourable circumstances for reproduction, does not bring forth a living and viable child. But the term is used with many other meanings, and I shall not state a definition, because I have no right or power to enforce adherence to it, and because, meantime, it is indispensable to have the word for various uses, and with the use of appropriate qualifying words ambiguity may be avoided.

Fecundity is a condition unique in gynaecology in this respect—namely, that it requires the combined matter and forces of two duly developed individuals to produce it. Sterility, therefore, may depend on error in one or in other, or in both.

The sterility of man as compared with that of woman is a simple matter. It depends on failure to produce semen, the production of semen more or less incomplete or imperfect, or of morbid semen (that is, semen conveying disease), or on failure to deposit the semen properly. With a view to investigation, the semen can be subjected to chemical and microscopical analysis, and the depositing organ can be examined and the conditions of deposition can be to a great extent ascertained. In woman the coördinate substances and functions are hidden and much more complex, and in her there are

great organs and functions which have in the male no equivalent representative.

In the present lectures the sterility of man is not a subject for consideration, but one point in it cannot be passed over without some discussion and estimation—namely, its numerical amount. Much of our knowledge of the sterility of women consists in numerical statements of amount under various circumstances, chiefly in marriages; and all such statements have a positive value for the physician, and still more for the political economist. But it is plain that, inquiring into the amount of sterility due not to unions but to women, we must exclude what is due to the male. Some good notion of the amount of this latter sterility is therefore indispensable.

Several investigators have attempted the solution of the question in recent times; but I refer only to the new work of Gross on Male Sterility. "It is not at all uncommon (says he) for physicians to assume that a man who is potent, and who is able to ejaculate, is capable of procreating. As a result of the omission to examine the emitted fluid, and carefully to explore the male organs, little is known of the relative frequency of sterility in the two sexes; and gynaecologists, with the exception of those mentioned below, do not appear to have made any contributions to the solution of this important subject. I have been able (he continues) to collect 192 cases in which examination of both the husband and the wife demonstrated that the former was at fault in thirty-three, or in seventeen per cent. Of this number Manningham records one in thirty; Pajot seven in eighty; Mondot one in ten; Kehrer fourteen in forty; Courty one in ten; Noeggerath eight in fourteen; and I myself have found that the male was deficient in one example in eight. The cause of sterility was azoopherism in thirty-one, and aspermatism in two. These facts show that the husband is at fault in about one case out of every six."

The matter is, however, still in a very insecure state, as may be shown by the statement of facts and con-

siderations which must have important bearings on the question, but which have, so far as I know, been entirely neglected. Thus, it is assumed that by examination of the male and female we can decide whether one or other or both are at fault. Now, no doubt impediments or complete barriers to reproductiveness may be found in individuals of either sex; but in the great majority of cases of sterility no impediment or barrier can be discovered by the most careful and minute investigation; and this is verified by comparative observations in animals and in plants, wherein such inquiries can be carried to a completeness not attainable in the case of men and women. It is held that the man is not at fault if he duly ejaculates microscopically perfect semen, but this is certainly not a warranted conclusion as facts in human and comparative physiology, to be hereafter stated in these lectures, will show. In making estimates of male sterility, no account is taken of the fact that the faulty condition of a man's semen may be only temporary. It is forgotten that sterility may be due to faults in the semen, even though conception has taken place, and pregnancy been established; the foetus fading and dying prematurely from inscrutable causes, or being monstrous and not viable, or perishing from disease implanted in it by the male. It is forgotten that both parents may be simultaneously at fault, and this with or without discoverable cause, generally without discoverable cause.

Speaking of the sterility induced by domestication and that of hybridity, Darwin remarks that in both the sterility occurs in various degrees, and in both the male element is most liable to be affected, but sometimes the female more than the male. In another place, speaking of the liability of plants to be affected in their fertility by slightly changed conditions, he says it is the more remarkable, as the pollen, when once in process of formation, is not easily injured; a plant, he adds, may be transplanted, or a branch with flower buds be cut off and placed in water, and the pollen will be matured. Pollen also, when once matured, may be kept for weeks or even months. The female organs are more sensitive, for Gärtner found that dicotyledonous plants, when carefully removed so that they did not in the least flag, could seldom be fertilised; this occurred even with potted plants if the roots had grown out of the hole at the bottom.

Whatever may be the causes of sterility in woman, there is a universally prevalent belief, which no investigations have shaken, that in the human species the paramount source of sterility is in the female. I know no scientific statement worthy of confidence as to the comparative influence of the two sexes; and the data of Gross, which I have quoted, contributing as they do towards the settlement of this question, are of importance and value in themselves, though they are far from substantiating the conclusion as to the amount of male sterility which he enunciates.

Of the sterility of women in whom, from gross and well-known causes, conception is impossible, these lectures take no account. Among such are cases of absence of uterus, and of imperforate vagina; conditions so rare that, in the present imperfect state of our knowledge, they do not affect statements as to women generally.

In describing sterility it is common to qualify it as absolute or as relative. No author on human sterility uses the term, without qualification, as including relative sterility. But when used without qualification it includes at least absolute sterility.

Absolute sterility, sometimes called congenital, including all cases where there is no child, no miscarriage, no abortion, however early, comprises two sets—first, those where there is no conception; and, second, those where the impregnated ovum disappears in the tube or in the uterus without leading to what is recognisable as an early abortion. Some cases of women aborting every month are known; there is discharge of a highly-devel-

oped decidua vera every four weeks, and there may be no trace of an ovum in it; and this monthly discharge is arrested by suspension of co-habitation. But there may be many abortions earlier than this without these conditions, and of such practically nothing is known; they are classed along with those cases of absolute sterility where it is supposed that no conception takes place. In cases where there is no conception there may be no possibility of conception from the failure of the ovary to prepare and mature an ovum.

These varieties of absolute sterility are well illustrated and easily made out in the history of animals, and still more of plants.

Sterility, not absolute, implies the failure to produce a viable child, while there may be evidence of conception—that is, of the commencement of the production of an embryo. A woman may be sterile because the ovum perishes in utero or becomes unnaturally developed, as in myxoma of the chorion and some monsters; and this premature death or unnatural production may be owing to ovuline imperfections derived from the male or from the female. A woman may be sterile because the womb does not afford to the ovum due accommodation, or nourishment, or neither; or because the womb ejects it prematurely from its cavity; and these unnatural conditions and events may arise from either local or constitutional causes.

In absolute sterility and in sterility not absolute there is no production of a viable child, no addition made to the population; and all such sterility is sometimes, especially by economists, considered absolute; for indeed, in the point of view of population, it is so. But it appears to me desirable to restrict the term absolute sterility to those cases where there is no evidence even of conception. Sterility indicates a larger group, including that of absolute sterility, and all those other cases where no addition is made to the population.

There is another great department of sterility no less important than the kinds just mentioned, where a woman may produce one or even several living children, but, in number, not according to her conditions of age and length of married life. This is called relative or acquired sterility. The gardener may have a plant producing not a single flower, absolutely sterile; or producing flowers, and setting seeds, but bringing none to maturity, or if to maturity, not to perfection, a sterile plant which cannot continue its species; but he may also have a plant which produces flowers and matures perfect fruit, but in such small number as not to save it from the charge of sterility; and this is relative sterility. In woman it is often seen in cases of production of a single child—an only-child sterility, if such a seeming contradiction in terms can be permitted, of which we often hear. A woman may be relatively sterile from producing, according to her age, only a small number of children with ordinary intervals between successive births, or from the number being rendered small by the extraordinary delay or loss of time between successive births, and in other ways.

All kinds of sterility may be congenital or may be acquired. It is therefore undesirable to use these terms as indicative of distinctions. For instance, an absolutely sterile woman, one who never conceives, may be so not merely from congenital causes, but also from disease acquired in advanced life; or, again, a relatively sterile woman may be so, not from an acquired cause, but from conditions which were congenital in her.

The amount of sterility in women (including the relative kind) is found by counting the number of productive and of unproductive marriages of women within the reproductive age, or from fifteen to forty-five. Lever, giving no numerical details, says that 5 per cent of married women are wholly unprolific. West found the average of sterile marriages among his patients at St. Bartholomew's Hospital to be 1 in every 85. Hedin, a Swedish minister, noticed that in his parish of 800 souls one barren woman is not met with for ten fertile.

Frank and Burdach roughly state that only one marriage in fifty is unproductive. Simpson made an inquiry into the sterility of married women in Grangemouth and Bathgate. Of 210 marriages in Grangemouth 182 had offspring; 27 had none; or about 1 marriage in 10 was without issue. Of the 27 unproductive marriages all the subjects had lived in wedlock upwards of five years, and in all the female had been married that period before she reached the age of forty-five. Of 402 marriages in Bathgate 365 had offspring; 37 had none; or about 1 marriage in 11 was unproductive. There was at the same time living in the village 123 relicts of marriages, and of these 102 were mothers; 20 were not mothers; or about 1 in 6 had no family. In all, of 467 wives and widows 410 had offspring; 57 had none; or about 1 marriage in 8 was unproductive. Of these last 57, 6 had not been 5 years married, and there were other 6 above the age of 45 when married. If we subtract these 12 we have of 455 marriages 410 productive, 45 unproductive, or 1 in 10 1-9th without issue. Simpson found that among 495 marriages of British peers which had lasted 5 years or more, and in which the husbands were under 57 years of age, 81 were unproductive, or 1 in 6 1-9th. Ansell found that among 1,919 marriages of spinsters in the upper class at an average age of 25 years, and not counting as childless those who had merely stillborn children, there were 152 without issue, or 8 per cent., or nearly 1 in 12. In this collection all the parents survived the childbearing age, and he considered that there was no further chance of childbearing if the female was

Over 48 and had had no child for 2 years.

I have taken the registers of Edinburgh and Glasgow for 1855, and have found the number of first living children in that year. With this I compare the number of marriages in that year. It is evident that the number of first children only should be counted, for they indicate all the wives who are not sterile. If one living child is born to a marriage, that marriage is not sterile. Further, it is evident that, although the first births in 1855 will not all pertain to the women married in that year, it may be assumed that if the marriages be nearly the same in number for a few contiguous years, the first births in one year will give the fertility very accurately of any of the contiguous years. From this fertility the sterility can be easily computed. Now in 1855 there were, in Edinburgh and Glasgow, 4 447 marriages, and 3,722 first deliveries of living children, leaving 725 marriages sterile, or 1 in 6.1. But in these figures are included 75 marriages which did not take place till after the women had passed forty-four years of age, and these will damage the physiological value of the statement, as these 75 women could not be expected to be fecund. Of women between the ages of fifteen and forty-four inclusive there were married 4,372; among women of the same ages 3,710 had first living children, leaving 662 marriages sterile, or 1 in 6.6. In other words, 15 per cent. of all the marriages between fifteen and forty-four years of age, as they occur in our population, are sterile. But this final estimate from the Edinburgh and Glasgow data has to be corrected for the dead born, these being not counted.

We have thus fairly good statements of the amount of fertility which are not very different from one another:—

Patients in St. Bartholomew's Hospital ...	1 in 8
Inhabitants of Grangemouth ...	1 in 10
Inhabitants of Bathgate ...	1 in 10
British peers ...	1 in 6.1-9
Upper classes (Ansell) ...	1 in 12
Inhabitants of Edinburgh and Glasgow ...	1 in 7

Omitting that of British peers, the highest estimate is the last, and it is probably the only one in which living children are used, to the exclusion of dead, as the index of fecundity. Were dead children included, there would be a great reduction—at least 4 per cent. The lowest estimate of sterility is that of Ansell. In it a woman having a stillborn child is held as fertile, and the women are the very best in the community, those living in easy circumstances and making use of the protection of life insurance; were it otherwise, the estimate of sterility would, no doubt, be higher. We have thus estimates of sterility varying from 1 in 7 to 1 in 12, and may have considerable confidence in laying down 1 in 10 as very nearly the true amount.

I know no estimate of those who are absolutely sterile—that is, who do not conceive, or who, if they do conceive, give birth to not even an abortion. But there are a large number in the better classes, for within the last five years there have consulted me at my house, mostly on account of sterility, 504 absolutely sterile women, married between the ages of fifteen and forty-five, and of these 336 were more than three years married. Though this shows a large number in existence, it gives no ground for an estimate of frequency among the married. The following table gives a classification of these 504 married and absolutely sterile women, according to age at marriage and number of years married:—

TABLE I.
Case-book Table of Sterility.

Age at marriage.	Years married.							Total

It is certain that all populations are relatively sterile; and the economist makes many estimates, such as the deficiency of offspring of the actual marriages, or the deficiency of the actual births below what they might have been had all the women in the population been married at the most favourable time for child-bearing. The solution of these and similar questions is an object of greater interest to the statesman than to the physician. They demand, for their solution much calculation, and need not be entered on here.

The degree or amount of relative sterility of the average individual varies, of course, according to the age at marriage, and it is not to be estimated by the deficiency below what is possible in child-bearing, but below the average amount of fertility in marriages at the various ages, or below what is not excessive, what can be done without injury to the average mother's health.

The average individual woman must be found and considered, for individuals vary extremely. It is not a rare observation, and I have one before me where the easy birth of a single child exhausted the fecundity of a healthy woman of twenty-five years of age at the time of the birth, and completely ruined her general health during the remaining child-bearing period of life. This woman was examined by many physicians, and all concurred in finding no cause of the weakness and the inability but the child-bearing. On the other hand, Ansell records the case of a woman married at twenty-one, who in twenty-seven years gave birth to twenty-

five children who all reached adult age, and the mother died of old age at eighty-eight.

Only-child fertility or one-child relative sterility occurs in two forms: as an exhaustion of the fertile energies leaving the general bodily health vigorous, or as an exhaustion of both sexual power and general constitutional strength. It is a relative sterility which is familiar to the public from its frequency and its importance in social respects. Ansell, in 1,767 fertile marriages, with a mean age at marriage of about twenty-five years, and allowing ample time for the exhibition of fecundity, as we have already stated, found 131 cases of one-child relative sterility, or 1 in every 13 fertile marriages. The degree of this relative sterility may be approximated by comparing it with the average fertility of the same women, which was nearly 6; or, in other terms, the relative sterility of these 131 only-child fertile women was 655. Instead of having 131 children, they would have had 786 children if they had even reached the average fertility of their 1,636 sisters, and they would have had still more if they had reached a normal fertility instead of this average fertility, meaning by normal fertility what they might have had without injury to health, judging them by other women.

There are several tests of relative sterility secondary to that implied in the paramount question, How many did she bear? These subsidiary tests are based on the ascertained course of natural fertility, and show the deviations from this course of the relatively sterile. Inquiry made by these tests implies a knowledge of how many children a woman will naturally bear, or is likely to bear, and of the natural order of births. They are as follows:—

1. When after marriage did she begin the career of child bearing? 2. How rapidly did the children follow one another? or, what was the interval between successive births? 3. When did childbearing cease? or what was the age at the birth of the last child? 4. How long was the child-bearing period of life? or, what was the interval between the beginning of the first pregnancy and the end of the last?

In studying population, these subsidiary matters are little regarded, for the statesman has direct interest only in the mutually related questions, How many are born? How many might have been born? What is the health of those born? The answers to these inquiries give him the actual relative sterility of the population, and in the case of a population this includes the absolute sterility. He may now attempt to increase or diminish the sterility of the people, not neglecting the health of the progeny, so far as it is related to fertility; and this control he will effect by raising or lowering the age at marriage. On the other hand, the physician, having care of individuals, not of a people, and advising each from year to year of life, has his chief interest in these subsidiary matters, which the statesman may not utterly neglect, but may leave to the care of the medical philosopher.

The importance of the question, How soon after marriage does a woman bear her first child? is self-evident, and it will be found to be more a test of sterility than it appears at first sight to be. Whitehead, founding on the observation of 541 married women of the average age of twenty-two years, makes the average interval between marriage and the birth of a first child to be eleven months and a half. Sadler says that married females do not become fruitful, on the average, during the first year of their nuptials, but nearly so. A great number of cases, he says, which he has collected, with a view of determining this point, gives three fourths of them as producing their first child at the average of one year after marriage.

From the Edinburgh and Glasgow registers for 1855 I was able to make out this point in 3,722 cases. But in these extracts from the register there are two sources of error, which prevent an exact comparison with the results of Ansell's more valuable table, for twins are

excluded, being placed in the column of secundiparæ, not of primiparæ. (See Table II)

And, still more important, the great number of mothers whose children were stillborn is excluded. Now, twins affect specially young, immature, and quickly breeding mothers; their omission, therefore, from the column of primiparæ will tend to delay the estimated time of primiparity. Again, a similar delay will result from the omission of women having dead children from the primiparous column, for such women, when they bear a first living child, which may be in reality a second, third, or other child, will appear in the primiparous column with an over-estimated and erroneous retardation of primiparity.

The Edinburgh and Glasgow table gives a mean interval of about seventeen months between the marriage and the birth of a living child. It shows that fecundity is not demonstrated by a living child in the majority of cases till a year of married life has passed; nearly two-thirds of the whole beginning their families in the course of the second year of marriage. It also shows that there is no ground for presumption of sterility till the fourth year of married life is entered upon; for while of those three years married and less than four 133 bore a first living child, there were only 154 who did so in all the subsequent years taken together. Of the whole 3,722 only about one twenty-fourth part began bearing living children after four years of married life had elapsed.

Ansell's table includes first stillborn children, and is corrected for twins, and gives us the data in 6,035 cases. It is therefore better than the preceding, and better than any other of which I know regarding this point.

Ansell's table gives a mean interval of nearly sixteen months between marriage and the birth of a child. The majority of the women in Ansell's table bore their first children before the first year of married life had elapsed—nearly seven-eighths before the expiry of two years of married life. It also shows that there is no good presumption of sterility till the fourth year of married life is entered upon; for while of those three years married and less than four 421 bore a first child, there were only 292 who did so in all the subsequent years taken together. Of the whole 6,035, only about one-twenty-first part began bearing children after the third year of

married life, and only one-thirty-ninth part after the fourth year.

It may therefore be held that married women delaying the commencement of fertility beyond sixteen months are already exhibiting a degree of relative sterility; and this conclusion is quite in keeping with the rest of our knowledge of this subject.

SANITARY LEGISLATION AND ADMINISTRATION AT HOME AND ABROAD. (a)

By CHARLES A. CAMERON, M.D., S.Sc.C. Camb. Univ.,
Fellow and Professor of Hygiene, R.C.S.I.; Medical Officer of Health,
Dublin; Honorary Member of the Societies of Hygiene,
Paris and Bordeaux.

(Specially reported for the "Medical Press.")

GENTLEMEN,—My first and most pleasing duty in taking the chair at this meeting, is to thank you for the honour which you have conferred upon me in electing me to the office of Chairman of the Sub-section of Public Health of the Academy of Medicine. It is a compliment which I appreciate all the more highly when I consider that many of those who have so kindly taken part in placing me in this position, are far more worthy of filling it than I am.

Gentlemen, those amongst us, who, like myself, are specially interested in the subject of sanitation, cannot but view with great satisfaction, the action of the Academy in founding a Sub-section of Public Health. By thus recognising the status of public hygiene, the Academy has not, I venture to think, over-estimated its importance. Every year the good work performed in this field of the domain of medicine steadily increases. Within the last dozen years, nearly all of the Universities and the Colleges of Physicians in the United Kingdom have instituted special diplomas in state medicine or certificates in sanitary science.

The history of preventive, as compared with curative, medicine, presents one remarkable difference: both began to be cultivated at an early period in the history of civilised man, but whilst curative medicine continued to be practised, preventive medicine in process of time practically ceased to exist. It is only now, after a lapse of many centuries, that the care of national health is again beginning to receive its fair share of attention.

The theocratic legislation of the Jews, whatever may have been its primary moral object, undoubtedly enacted a most admirable code of sanitary laws, the effects of which continue to the present day. Plato, in his Ideal Republic, recognised the importance of having a proper sanitary supervision of the city. His contemporary, Hippocrates, has described the duties which the city physician should discharge. This ancient philosopher attached great importance to such matters as the site, aspect, and quality of the water supply of cities. In his advice to a young physician, he indicates how he may by examining into local conditions of a city, predict the epidemics which would be certain to visit it. Zenophon, in his *Cyropædia*, has given a true definition of the difference between the ordinary physician and the professors of preventive medicine. The former, he says, cures people when they are sick, but the latter have a nobler duty to perform—they keep people from becoming sick.

From the period of the decay of Greek and Roman civilisation until the 19th century, little seems to have been done for the express purpose of promoting the national health. Politics and wars engrossed the attention of the governing classes, and the public health was left to take care of itself. No doubt, from the time of the Norman conquest, edicts of kings and acts of parliament have been directed against certain sanitary evils, but their effects were transient. In Ireland, so far back as the eighteenth year of the reign of Charles II, parliament passed an act forbidding, under heavy penalties, the adulteration of

alcoholic liquors. In 1717, a kind of public health act for Dublin was placed on the statute books of the Irish parliament. Similar acts were passed by the English parliament, but their provisions soon became dead letters, as there was no effectual machinery for carrying them into effect. I am disposed to believe that the first comprehensive general sanitary act, passed by any modern legislation, was that enacted by parliament in 1818; it applied solely to Ireland.

In England, the terrible ravages of the cholera in 1832, and the eloquent writings of Southwood Smith, Andrew Combe, and Chadwick, showing how the mortality from cholera and other causes might be lessened, profoundly moved the public mind. In 1835, the first essential part of a natural health organisation, namely, a vital statistics department, was established; and soon after the admirable reports of Farr began to be issued. One of the immediate results of the reports of the Health of Towns Commission, issued in 1844 and 1845, was the passing of the Public Health Act, and the Nuisances Removal and Diseases Prevention Act of 1848. Those Acts gave great powers to the local authorities. An admirable act, called the Towns Improvement Act, was passed for the benefit of Ireland in 1847, and its numerous sanitary clauses were incorporated with the Dublin Improvement Act of 1849. If the local authorities had been obliged to carry out the provisions of this Act (Towns Improvement), great benefit to the public health would undoubtedly have been the result. In some respects it is superior to the Public Health Acts of 1878. For example, it enables local authorities to deal effectively with houses which have become derelict and ruinous. Under its provisions, I have lately had several successful prosecutions for the sale of unsound and adulterated food, the vendors of which could not have been reached under the provisions of the Public Health Act, or Sale of Food and Drugs Act. It seems to be forgotten that the Towns Improvement Act has clauses still in force which deal with many sanitary evils.

The fatal defect in all the sanitary acts passed prior to 1873, was the merely permissive nature of the powers which they conferred upon the local authorities; the great merits of the Public Health Acts of England (1875), and Ireland (1874), and of the acts amending or codifying sanitary laws, passed since 1874, are the mandatory nature of so many of their provisions, and the creation of a powerful controlling central authority. They have also the merit of having created rural sanitary authorities. There are, no doubt, defects in these acts, especially in reference to the status and remuneration of the medical officers of health appointed under their provisions; still, we should loyally accept them as substantial instalments of sanitary reform. A brief examination of the powers now vested in local authorities reveals their extensive range, and their great capabilities for improving the health of communities—always provided that they are wisely administered. Unhealthy areas can be cleared, houses unfit for habitation can be compulsorily closed without any compensation to their owners, proper dwellings can be erected for the labouring and artisan classes, hospitals can be maintained, infected clothing and bedding can be destroyed and compensation given to their owners, not only public but private scavenging may be carried out, main sewers can be made, and the construction of house drains can be enforced, dwellings and clothing can be disinfected, noxious trades can be regulated or prohibited, there is not a single nuisance that cannot be reached; abattoirs, baths and wash-houses, play-grounds for children, and public parks can be provided. The local authorities may provide mortuary houses and cemeteries; the inspection of markets, slaughter-houses, factories, bakehouses, lodging houses, and tenement houses is entrusted to them; they can make regulations for new streets and buildings, and for houses being rebuilt or undergoing extensive repair; they can widen thoroughfares, and open up new streets; even a chandler cannot establish a candle factory without their permission.

Without the aid of a department of vital statistics it would be impossible to measure the amount of good

(a) Read before the First Meeting of the Sub-section of Public Health of the Academy of Medicine in Ireland, Feb. 9.

effected by sanitary improvements, Ireland is fortunately circumstanced in this respect. Recent legislation has rendered it almost impossible that any deaths occurring, at least in a town, should escape registration. Ireland, too, has the advantage of having the important position of its Registrar-General filled by an enlightened sanitarian, and not by a mere statistician. Ever since his assumption of his present duties, Dr. Grimshaw has steadily effected improvements in the returns of births and deaths. Since the beginning of the present year he has had introduced a new feature into these returns, which, so far as I know, is not to be found in any similar publication. I refer to the tables in which the death-rates amongst each of eighteen distinct classes of the population of Dublin are given. I trust that similar tables may soon be found in the returns for London, Edinburgh, and other large towns.

I shall now very shortly describe the administration of public health affairs in some of the more important foreign states.

In France, the Société Royale de Médecine, established in 1776, was the only council of health in that country until the foundation, in 1802, of the *Conseil de Salubrité*, of Paris. Twenty years later a similar body was established at Lyons, and later on, at Marseilles, Lille, Nantes, Troyes, Rouen, and Bordeaux. In 1822 a *Conseil Supérieur de Santé* was attached to the Ministry of the Interior, but it exercised but little influence upon the subordinate councils.

It is somewhat remarkable that in 1848 sanitary legislation first began to have an air of reality about it, both in France and England. The Supreme Council of Health was suppressed, and in its stead there was founded a *Comité Consultatif d'Hygiène* attached to the Ministry of Agriculture and Commerce. At present, this committee is composed of twenty members. Nine members are Government officials, and of the remaining eleven who are nominated by the Ministry, eight at least must be doctors of medicine. The Council supervises or offers advice in reference to the following, amongst other matters:—Quarantine, etc., distribution of vaccine, the inspection of drugs, food, poisonous colours, and the means of controlling epidemics, the sanitary state of factories and dwellings, the care of the public baths and mineral waters. It receives annual reports from the provincial sanitary authorities, and it suggests certain questions for the consideration of the National Academy of Medicine.

In the provinces there are *Conseils d'Hygiène et de Salubrité* for each department, and *arrondissement*. They consist of from nine to fifteen members appointed by the *prefet* for four years. They are presided over by the *sous-prefet*. They must meet at least once in three months. *Commissions d'Hygiène* exist in the chief places of the cantons; they resemble the councils, and are presided over by the *maire*. It is worth remarking that if a council consists, say of twelve members, five of them must be doctors of medicine, surgeons, or *officiers de santé* (a low grade of practitioners, and not health officers as we understand the term), three pharmacians, or chemists, and one veterinarian.

Paris and its environs are under the jurisdiction of a specially formed body, the *Conseil d'Hygiène Publique et de Salubrité au département de la Seine*. It consists of twenty-one members appointed for an indefinite period; each member receives a salary of £48 a year.

At Havre, Nancy, and Rheims, *Bureaux d'Hygiène* have been established; in the two former in 1879, and in the latter in 1882.

The actual administration of the sanitary laws in France is almost altogether in the hands of the Government. The staffs of the councils of health are in general very limited. The sums expended for public health purposes in the departments appear to be very small. In 1881 some of the departments did not spend £100 for these purposes. In the great department of the *Seine Inférieure*, the expenditure did not exceed £200. In Paris

there is a more liberal expenditure. The sanitary laws are, to a great extent, administered by the Government, but certain important duties are carried out by the municipality. For example, although a laboratory for public health purposes and for toxicological analyses has been, since 1878, attached to the prefecture of police, the Municipal Council of Paris established a larger one in 1881. It is under the direction of Dr. Girarde, who is assisted by a staff composed of no less than fifty-one persons. Quantitative analyses are made for the public without any charge, and for qualitative analyses a fee of from five to twenty francs is charged.

The Bureaux of Havre, Nancy, and Rheims closely resemble the sanitary authorities of British towns, except that they supervise the collection and publication of vital statistics.

In the departments the sanitary staff under the *Prefet* consists of a director and two inspectors; they are assisted by a sufficient number of police.

In Paris, in 1882, there was a chief sanitary inspector at a salary of £240, six first class inspectors at £160 per annum, and six second class inspectors at a salary of £120 a year. The duty of inspectors is to examine houses to ascertain their fitness for habitation, and factories in which noxious trades are conducted, &c.

There are in France numerous councils charged with the examination of animal food, and with the subject of the investigation of epizootic diseases. The service termed the *Comité Consultatif des Epizooties*, the *Vétérinaires Inspecteurs* (one for each department), and the *Vétérinaires Cantonaux*, was re-organised and rendered more effective in 1881.

The weekly publication of vital statistics is only a recent institution. The hebdomadal returns issued in Paris are very complete documents.

The number of French statutes and decrees in reference to sanitary affairs is very large, and, on the whole, well designed. They are not, however, properly administered in a large portion of the country, and the expenditure of money in effecting sanitary improvements, more especially in providing good water supplies to towns, and properly draining them, is too small.

In the present German Empire there has existed since 1876 a superior Council of Public Health composed of five members, viz., a director, a statistician, a physician, who has made sanitation a special study, a chemist, and a veterinarian. There are besides ten extraordinary members, of whom two are government functionaries, four are physicians, devoted to studies relating to sanitation, &c., two chemists, one pharmacian, and one architect. The Council supervises the distribution of vaccine lymph, the sale of drugs, the programmes for professional examinations of medical men and veterinarians. It suggests new laws for the improvement of the public health, and it conducts original scientific researches. Offences against the sanitary laws are punishable by fines and imprisonment. In Prussia there is a ministry for sciences and medical affairs. There is a sanitary police, but there is no properly organised department of public health. In each province there is a superior office of the State who supervises affairs, medical, sanitary, pharmaceutical, and veterinary. He is advised by a provincial medical college composed of five or more members, including a pharmacian and a veterinarian. With the exception of the President, the sanitary police are wholly under the direction of the Provincial Governor, each of whom is advised by a medical councillor. In the smaller divisions of the country the sanitary police are directed by a *landrath*, who is advised by the district physician, or *kreisphysikus*. The carrying out of the sanitary laws devolves upon the ordinary local police. An ordinance promulgated in 1835 enacts that every town containing more than 5,000 inhabitants shall be provided with a sanitary committee. In some towns this ordinance has not been carried into effect, and in the towns in which there are committees they appear to be even less active public health authorities than the rural boards of guardians in Ireland. On the whole, with the

exception of the inspection of food and drugs, and of factories, the public health administration of Russia certainly admits of great expansion and improvement. The collection and publication of vital statistics are pretty fairly carried out. In Bavaria there is a public health department of the ministry of the interior. It is composed of a permanent staff of *medicinal referenten* nominated by the King, and of delegates from the three universities and the local bodies, termed the Medical Chambers. The committee is consultative and has the right to initiate sanitary laws, but it has no administrative powers. In the provinces there are Medical Councils for the circles and cantons. Each district judge has the services of a physician or *bezirkärzte*, of the second class, who appears to be a kind of general medical expert and inspector. He deals with vaccination, the registration of deaths, inspection of hospitals, food, drugs, &c., and performs post-mortem examinations. An expert of this kind is generally to be found throughout Germany. In Austria and Switzerland a *bezirkärzte* of the first class is appointed in each canton. There is inspection of industrial establishments, of places in which food and drugs are prepared and sold, and where poisonous pigments are manufactured. The chief work falls upon the police. There does not appear to be regular systematic inspection of tenement houses. The town authorities are not specially urged by a central power to improve the sanitary condition of the towns.

In Austria sanitary affairs are almost wholly administered by the Government. The purely consultative bodies seem to exercise little influence in the origination of sanitary reforms, or the administration of sanitary laws. The police do nearly all the inspectorial work, and there are of course scientific experts to assist the authorities. Vital statistics have recently been commenced to be published weekly.

In Belgium the local authorities have a large share in the administration of the sanitary laws. The *Bureau d'hygiène* of Brussels, instituted in 1874, by the Medical Commission of the City, has a strong staff; it inspects the schools, and dwellings, and acts very similarly to a British local authority. It publishes vital statistics, supervises vaccination, and administers the laws affecting prostitutes. The superior officers consist of a director, five divisional medical officers, five assistants, and two medical inspectors of prostitutes. Throughout the provinces the central sanitary organisations are imitated more or less closely. Some of the sanitary laws of Belgium are excellent, but the greater number relate merely to unsound or adulterated food, and to drugs.

In Holland the minister of the interior is the chief of the sanitary administration; he has no advising Council, but of course he has a *referent*. There is a large number of medical inspectors and assistants, who are wholly in the pay of the State; they do not practise. There are provincial councils composed of from six to ten physicians, two to six pharmacists, and the official inspectors. There are numerous sanitary laws, one of which in reference to the compulsory notification of infectious diseases contains very strict clauses.

In Switzerland each canton has its own sanitary laws, and administers them on the whole, at least as effectually as German States do. The most complete sets of laws appear to be those of Geneva, Zurich, and Bâle. Some general laws of the Confederation deal with the control of certain industrial employments, and with epidemics. In Switzerland there are public analysts.

In Italy, Acts of Parliament passed in 1865 and 1870, and a Royal decree issued in 1873, enact an extensive sanitary code, based somewhat on the model furnished by France. The minister, the prefect of the province, and the maire, or Sindaco of the district, are the principal directors, whilst the police are the ordinary agents. The medical practitioners are chiefly graduates of the universities; but quite recently a lower grade of practitioners have been created under the title of surgeons: they correspond to the English apothecary of the present century, and to the French *officier de santé*.

In Scandinavia the greatest attention is given to public sanitation. The sanitary laws are very comprehensive. In the larger towns there are medical officers of health with functions analogous to those of our own health officers. In Denmark the care of national health is at least as well attended to as in England.

In Stockholm and Copenhagen there are sanitary associations, and a valuable journal of hygiene is published in the former city.

With regard to Spain, I have but little information to give. There are sanitary laws and a vital statistic department; from the latter very elaborate and beautifully executed demographical charts and tables are issued.

Of the sanitary laws of Russia I know nothing. Its towns appear to be on the whole very unhealthy, and St. Petersburg stands highest in its bills of mortality amongst the capitals of Europe.

In the great Republic, on the other side of the Atlantic, much has been done towards the preservation of the national health. On this subject a very long address could be delivered, but time will now permit me only to say a few words in reference to the sanitary organisations of the United States. The most important health organisation is the "National Board of Health," Washington. It collects vital statistics on sanitary information, institutes original investigations in reference to the etiology of disease, and other points, and extensive inquiries and suggestions as to quarantine regulations. It has very little administrative powers. Its expenditure from its foundation—April 1st, 1879, to June 30th, 1882—was £108,500. It issued once at least a week, a very interesting Bulletin, which about six months ago was discontinued for want of funds. The Board's estimate for expenditure for the year ending June, 1884 is £25,000. In all the large towns of the Union there are municipal sanitary organisations closely resembling those of our own towns; but they are not subject to any central authority such as our Local Government Board. A large number of the States have Boards of Health which publish elaborate vital statistics. Some of the Boards (notably that of Massachusetts) publish interesting sanitary essays, some of which contain original matter. The collection of vital statistics is accurately conducted in only a minority of the States. It may be said generally of the United States that the sanitary administration is nearly in the hands of the municipalities. There are some excellent codes of sanitary law in individual States, notably in Massachusetts. I think it better not to go into details with respect to the *personnel* and duties of the American sanitary authorities, as I could not possibly at present without unduly trespassing upon your time, give even a sketchy description of these numerous bodies.

And now it remains but to thank you for the patience with which you have listened to this rather rambling address, and to express the hope—in which I am sure you all join—that our sub-section of public health may become one of the most active and important of the departments of the Academy of Medicine in Ireland.

Clinical Records.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

Tubercular Meningitis.

Under the care of Dr. C. E. ARMAND SEMPLE.

LILLIAN W., æt. 4, admitted Sept. 6th, 1882.

History.—Had measles three years ago. No scarlatina. No pertussis. Acute rheumatism two years ago; has not had another attack since, but has been occasionally ill. Losing flesh and easily getting out of breath. Never had any dropsy. No cough. Has suffered from vomiting one week. Bowels regular. Has been hot and restless at night, but has had neither squint nor convulsions. No pain. No rash.

Family History.—Mother's family consumptive. Mother

has had two miscarriages and one child still-born. Father suffers from palpitation of the heart. An uncle had acute rheumatism.

Condition on Admission.—Patient lies curled up in bed, in a constantly drowsy condition; frets and cries when disturbed. The skin over abdomen is dry, shrivelled, and inelastic. The tongue foul, slightly brown in centre. Lung sounds, normal, except slight wheezing over back. No dulness. Heart sounds irregular.

Urine.—No albumen. On addition of nitric acid to the cold urine, a precipitate of nitrate of urea fell.

Sept. 7th.—Still drowsy, and frets when disturbed. Signs a good deal. No sickness. No cry. Motions natural.

9th.—Last night, about 9 p.m., patient became very restless and wandering; called out repeatedly for water, and talked strangely. Showed signs of irritation on the slightest noise or disturbance. Later on an icebag was applied to the head. At about 2 this morning, she began to scream and cry loudly; was removed to the special ward, and given a dose of chloral and bromide of potassium. This, however, had no effect, and she continued noisy until 7 o'clock, when she became quiet. Still shows signs of irritation when disturbed, but otherwise lies quiet. Lips dry and parched. Will answer when spoken to two or three times, and denies feeling any pain. Pulse irregular. Plantar and abdominal reflexes marked. Skin over abdomen remarkably inelastic. No marked *tâche*. The optic discs on examination were noted to be obscured at the edges, especially the right disc, and the vessels to be somewhat tortuous.

10th.—Slept all night, but talked in sleep, and screamed three times. Occasional twitching of both hands and right leg. Seems not to know her mother, but puts out tongue when required. Tongue dry and furred. Abdomen slightly retracted. Skin very inelastic. Well-marked *tâche*. Slight rigidity about arms only. Hands tremulous. Swallows well. Face flushed.

11th.—Irregular movements of hands continue. Veins about forehead prominent. When disturbed, internal strabismus of right eye. Plantar reflex exaggerated. Skin not so inelastic. Passes urine under her. Bowels confined. *Evening.*—Sweating profusely. Face flushed. Tremors continue. Does not swallow so well. Breathing irregular, somewhat Cheyne-Stokes in character. To have enemata of beef-tea and milk every two hours. Brandy ʒj. every four hours.

12th.—Face very flushed. Perspiration profuse. Pulse rapid and weak. Convulsive tremors continue. Breathing very irregular. Cannot swallow anything. Enemata retained. Slight rigidity (in flexed position) of elbows, which tend to be kept drawn up, with hands resting on clavicles. Left foot rigidly pointed. Occasional rigidity (in claw form) of left hand.

13th.—Condition much the same. Blowing out of cheeks with respiration. Fingers, wrists, and elbows flexed. Occasional convulsive movements of hands and arms, and tremors. Face flushed. Abdomen much retracted. Pulse-rate not obtainable. Died in the afternoon; two weeks after commencement of any symptom, one after admission.

No autopsy permitted.

SIR ERASMUS WILSON, LL.D., F.R.S., has headed the subscription list of the Egyptian Exploration Fund with a donation of £500, and has accepted the office of president.

CLINICAL SOCIETY OF LONDON.

FRIDAY, FEB. 23RD.

ANDREW CLARK, M.D., F.R.C.P., President, in the Chair.

Dr. BROADBENT ON

CASE OF SUPPOSED HYDROPHOBIA TREATED BY CHLORAL WHICH RECOVERED.

Case I.—The patient, a boy *æt.* 12 or 13, was admitted into St. Mary's Hospital on February 25th, 1876, suffering from violent convulsive attacks which had been going on for two days. The paroxysms were ushered in by a loud, deep breath, and there were first momentary rigid extensions of the body, followed by rapid rotatory movements of the head with loud laryngeal sounds, which lasted two or three minutes, after which the boy moaned and complained of pain in the head. These attacks were at once brought on by an attempt to drink, by the sight or sound of falling water, by the contact of a cold object or pressure on the heart, or by light thrown into the eye in attempts of ophthalmoscopic examination. In the intervals the boy was conscious and fairly clear in intellect, his countenance was pale and anxious, the skin clammy, temperature normal, pulse 108, small, weak, and hesitating; respiration, sighing. There were frequent extensive jerks of the body and limbs. The idea of hydrophobia had occurred to his parents, but the only dog the boy was known to have played with was alive and well. The boy himself spoke only of the same animal until directly asked if he had ever played with a strange dog, when he said he and some companions had found and shut up a strange dog, and that it had bitten him on the hand, but he had forgotten which. There was found, however, on the fleshy part between the thumb and finger of the right hand a small scar surrounded by an extensive induration like that of a chancre. After a trial of nitrate of amyl with no good effect—chloral, 20 grains; brandy, 1 oz; and beef jelly, 2 oz., were given by the bowel every three hours. The boy slept, had only slight occasional spasms, and was soon able to drink milk. On February 28th, he was apparently well, and the chloral was suspended; but on the evening of the 29th he had a violent relapse, which continued on March 1st. Chloral was again given till March 11th, when he had been up and running about the wards for several days. He remained in the hospital till April 2nd, and was kept under observation for some time longer. When he was taken to the hospital chapel the first notes of the organ threw him into a state of uncontrollable excitement, with violent throwing about of the arms, and he could not, for a time, bear the sound of barrel organs. The case was submitted to the Society exactly as it was written out six years before from the notes of Mr. Jackson Garrett, at that time resident medical officer. If the boy had died there would have been no doubt as to the disease being hydrophobia. The symptoms, while not corresponding in all particulars to those seen in some fatal cases, were extremely similar, and the induration round the bite was corroborative evidence. The circumstances excluded emotional excitement as a cause of spurious hydrophobia, and there was nothing in the boy's previous history or character to suggest that he was a likely subject for hysterio-epileptic simulation of the disease. Chloral was given partly because it seemed best adapted from its physiological effect to relieve the spasms, partly in the hope that it might rob death from such a disease of part of its horror.

Case II.—A healthy girl, a month after being bitten by a strange cat, complained of nausea, sickness, and loss of power in the arms, and next day, after feverishness and thirst, became excited and unmanageable, and was brought to the hospital at 10 p.m., July 31st, 1881. She was excited and delirious, but could answer questions; asked for water, but could only take it out of a spoon after hesitation and with evident effort: it was swallowed with difficulty, and provoked spasm of the pharynx and neck. Chloral and bromide of potassium were given in beef-tea by the rectum. During the night the child became rapidly worse, more delirious and excited, with hawking up of viscid mucus, and complete inability to swallow. She died exhausted less than seventy-two hours after admission. At the post-mortem

tem examination, there was some congestion of the brain and upper part of the spinal cord, especially in the floor of the fourth ventricle, and sections of cerebral cortex and all other parts showed congestion of vessels and a few punctate extravasations into the perivascular spaces, but no cellular infiltration.

PSUEDO-HYDROPHOBIA—DEATH.

Case III.—A man, æt. 26, who had gone through much excitement and anxiety, which had led to more or less alcoholic excess, five years after being bitten by a dog, was suddenly seized with choking while drinking spirits after giving evidence in a court of law; apparently some of the liquid got into the larynx. He was seized with panic that he was going mad. After three days' excitement and sleeplessness he was brought to St. Mary's Hospital on Oct. 25th, 1876, about 10 a.m., in a wild and anxious condition, dreading the approach of liquids, and in any attempt to swallow seized with spasms of the pharynx and neck and gasping for breath. He swallowed solids. He could be quieted by firmness, but soon relapsed. Among his complaints one was that he was in a fog and could not breathe, another that he was going to be murdered. He hawked and spat, and pulled at his throat. During the evening, after removal to an isolated ward, he was quieter, and could drink liquids. In the night he slept at times, at others was noisy, and he tried to strangle himself, and to get out of the window. On the morning of the 26th, he was calmer; through the day his condition varied, but at 4 p.m. he was rational and tranquil, and eating bread and milk. Soon after this, the visit of his wife and child brought on a paroxysm of greater and more violent excitement. In the evening he was put under chloroform, and could then both breathe and swallow. The excitement, however, returned, and was followed by exhaustion, and he died about 10.45 p.m. At the post-mortem examination, fifteen hours afterwards, the *rigor mortis* was very great. All the internal organs, but especially the lungs and kidneys, were congested. The membranes, cortex, and white substance of the brain, pons, and medulla were greatly congested, as was also the spinal cord. There were no embolisms.

Case IV.—The patient, a boy, æt. 13½, was admitted January 18, 1883. He had been bitten by a puppy, three months old five months previously, on the finger; the wound was cauterised within five minutes, and twice subsequently; the dog was confined, and a week later killed, because it was then thought to be going mad. The boy read all the accounts of cases of hydrophobia he could find, and constantly talked about it. On January 15th he had pain in his back, but up to the 17th had only symptoms of a bad cold. On January 18th he could not swallow liquids or suck an orange; spasms were induced by the attempt. There was an excessive flow of saliva and foaming at the mouth. He started up at times saying he could not breathe, and was excited. On admission the prominent symptom was emotional excitement. He would not allow liquid to be brought near him. The abdomen was retracted and hard. Face flushed and wild. Pulse frequent. Temp. 107°. An enema of gruel and castor oil was ordered, and after this an enema of beef jelly, brandy (half an-ounce), and chloral (twenty grains) every three hours. Three hours later he asked for and tried to drink milk. It was with much difficulty that he got the spout of the feeding-cup to his mouth, and when he did so the fluid provoked a most violent spasm of the neck and arms, and great respiratory distress. He afterwards, however, sucked an acid-drop, and swallowed the saliva. Respiration, irregular and jerky, 36. Much moaning and whining. Pain and tenderness at epigastrium. The gruel and castor oil did not return, and the beef-tea and chloral had to be given upon it at 7 o'clock. During the evening and night the patient became more and more excited and violent, starting up, clutching throat with both hands, beating his head against the wall, screaming, and saying he was choking. The respiration was rapid, catching, oppressed; the pulse extremely frequent; perspiration pouring off the face; at times convulsive paroxysms of neck and arms. At 11 p.m., after a second chloral, brandy, and beef tea enema, he was so violent that restraint by bandages was necessary. At 2.45 twenty grains of chloral was given hypodermically, and the patient slept three hours. At 10 a.m. of the 19th he was quiet, listless, and drowsy, but contact of the hand, or turning down the bedclothes, caused a long deep inspiration. He complained of no pain. Respiration more even; pulse 130, small and

weak; temp. 107°. At 11 a.m. the urine had to be withdrawn by a catheter. The amount was sixteen ounces; the sp. gr. 1030; no albumen or sugar, but urates thrown down on cooling. After this the spasms were slight and infrequent, but the exhaustion increased. There was much foaming of the mouth. The temperature remained at about the same point. Sordes formed on the teeth. The patient died at 10.25 a.m. on the 20th, about forty-three hours after admission. The administration of chloral was suspended when the spasms ceased, beef-tea and brandy only being given. On post-mortem examination three hours after death the *rigor mortis* was extremely pronounced. The cerebral meninges, cortex, and white centres were extremely congested. Puncta cruenta more numerous and large. Membranes over pons and bulb milky and specially congested. No excess of serum in ventricle. Nothing noteworthy in chest or abdomen, except two living round worms in small intestine just above the valve.

The author added that he was convinced the last two cases were not true hydrophobia; that of the man obviously was not. These spurious cases seemed to warrant the assumption that the higher nervous centres might so influence the lower as to create reflex spasms apparently characteristic of hydrophobia. This also afforded an explanation of the connection between the symptoms and appearances—that is, of the relation borne by the dynamic changes which preceded the structural wreck revealed on post-mortem examination. The first case was that of a boy, æt. 13. His urine was normal throughout, containing no albumen or sugar. The little girl was also æt. 13—the man, 26.

Dr. DYCE DUCKWORTH congratulated Dr. Broadbent on the successful result obtained in the first of his cases, which, Dr. Duckworth considered, was certainly one of hydrophobia, and exhibited a most complete and typical train of symptoms. The employment of chloral as a remedy reminded him of a case occurring some years ago in which administration of this drug *per rectum* undoubtedly prolonged life. Chloral was certainly as useful as any remedy in hydrophobia, but he thought Dr. Broadbent had obtained the first cure by its use. It should be given by the rectum, and in combination with nutrient enemata. He suggested that the most certain test of hydrophobia was that afforded by a current of air directed into the sufferer. If it produced the typical phenomena of hydrophobia, it would indicate a real attack, as patients simulating the condition would fail to attach any importance to the experiment, and would not react to it. In time he hoped a remedy for hydrophobia would be discovered.

Mr. PICK doubted whether the case should be regarded as one of true hydrophobia chiefly because the symptoms, commonly experienced, of pain in the wound originally inflicted by the infecting animal were absent; general *malaise* preceding the attack, and mental terror in the intervals separating the paroxysms also seemed to have been unnoticed, on which account as well he would hesitate to accept the case as one of true hydrophobia.

Dr. WHIPHAM asked whether the cervical spasm was always present in these cases? He had not seen any instance of the disease in human beings, but in the cases of three rabid animals he had examined—one of that of a sow, the other two of dogs, he had failed to detect this spasm of the neck.

Dr. WM. EWART commented on the confusion introduced by the application of a different terminology to essentially similar diseases. He contended that the virus of rabies in a dog ought to be held to communicate *rabies* to any other animal infected from it, and if the result of such inoculation occurring in the human being were true hydrophobia, what, he inquired, was false hydrophobia? One set of cases might exhibit post-mortem changes which would be sought in vain in the other series, and it might be said, therefore, that the infiltrations always declared to be present in the medulla of patients succumbing to attacks of true hydrophobia were characteristic of that disease. In two cases narrated by Dr. Broadbent, in which the spasmodic symptoms were present, fatal terminations were recorded, and the assumption that death invariably followed when these characteristic symptoms of true hydrophobia were developed made it of the first importance to discuss the subject fairly and fully. The necessity for precision in the employment of terms descriptive of the conditions induced under different circumstances offered additional reasons for insisting on this course. In absence of all knowledge as to the curability of hydrophobia.

by destruction of the virus, it would be unjustifiable to prejudice the question. Dr. Ewart believed that careful examination of past records of cases of hydrophobia might reveal instances of recovery, and he urged it was fallacious and unphilosophical to form hasty judgments on the question on the evidence afforded by the fate of the dogs from which the disease had been contracted.

Dr. LONGHURST said it would be interesting to know what amount of chloral had been administered during treatment of the cases. This knowledge might be of assistance in defining the pathological changes observed.

Dr. ANDREW CLARK requested Dr. Broadbent to explain the precise differentia which led him to term the first case true hydrophobia and the others false; and also to explain his meaning in speaking of influence exerted over the lower by the higher nervous centres. The age of the boy was, he suggested, that at which the nervous system might be expected to influence the exhibition of *bizarre* effects.

Dr. MAHOMED considered that every one present to whom opportunities presented of experimenting with the virus of hydrophobia should pursue such a line of investigation. To his query whether the Government would grant licences for this purpose,

The PRESIDENT replied that such applications would certainly be refused.

Dr. DUCKWORTH mentioned that such experiments had been conducted at St. Bartholomew's Hospital.

Dr. BROADBENT admitted the necessity for possessing distinctive names for the various forms of disease under consideration. Evidence of specific inoculation through a rabid animal was the essential differentia of true hydrophobia as he conceived it, and it was observed in his case where the patient recovered, in which also there was tenderness, &c., at the seat of injury, thus aiding the diagnosis between true and false hydrophobia. In the case of the man the disease was of the spurious kind, and had been induced by abnormal conditions set up by irregular living, drink, &c. In the other cases where proof of specific inoculation was deficient there were traceable such influences as might have occasioned nervous disturbances. The first case was free from any suspicion of such influences, however, and, moreover, there was a deficient train of circumstances by which to associate the occurrence of disease with the infliction of a wound by biting, which wound clearly cicatrised. In the last fatal case, a boy, 220 grains of chloral were administered. Exactly how much had been given to the boy who recovered was uncertain.

Dr. J. K. FOWLER on

TWO CASES OF PSEUDO-HYPERTROPHIC PARALYSIS IN ADULTS.

Case I.—A male, *æt.* 40, a blacksmith. *Family History.*—No evidence of heredity. A brother similarly affected *Case II.* The patient has had four attacks of acute rheumatism. Twelve years ago he was noticed to have a peculiar swaggering gait. Five years ago he himself noticed that he had difficulty in ascending stairs, that he was easily tired by walking, that he could not rise from a chair without difficulty. He was an in-patient in the Middlesex Hospital in 1879. His weakness increased subsequently, and he frequently fell down. He noticed in December, 1880, that he could not stand steadily with his eyes shut. In January, 1882, he observed that his legs and arms were increasing in size. There has been no difficulty in micturition or defæcation. Mental power is unimpaired. The patient has the characteristic attitude and gait of the disease as seen in children. He cannot rise from a chair without great effort. When placed upon his back on the ground he is powerless to rise. The triceps on both sides and *infra-spinati* are remarkably enlarged; both biceps are atrophied. In the paper various measurements are given, showing the gradual change in the circumference of the arm and calf. The electrical reactions are given in detail. The paper is accompanied by photographs of the patient, and drawings and microscopic specimens illustrating the condition of the muscles. Reasons are given for regarding the disease as essentially the same as that occurring in children. Other cases in adults are cited.

Case II.—Brother of the above. He has lately been noticed to have a difficulty in ascending stairs. There is marked enlargement of the muscles and of the calf and triceps of both sides. The case is detailed on the same plan as *Case No. I.*

Dr. BROADBENT observed that these cases were highly interesting, and had been most carefully and accurately

reported. He instanced the case of two sisters aged between eighteen and twenty, in whom this condition was observed. He was struck by the much less pronounced degree of hypertrophy seen in adults as compared with children. The primary change was clearly atrophy. He had seen an instance in which the disease was coming on in a patient about fifty years old, but with an appreciable hypertrophy; and the suspicion was justified that a disease hitherto supposed to be confined to children occurs also among adults, in whom especially atrophy is a conspicuous feature.

Dr. GREEK mentioned a case in which the disease followed injury received by a patient twenty-two years old, and in which enlargement as marked as occurred in children took place.

Dr. EWART was glad to hear Dr. Broadbent's account of the disease in women. He had seen a case in St. George's Hospital in which the age, thirty-five, aroused doubt, but the want of symmetry in the corresponding muscles confirmed diagnosis. He asked if Dr. Fowler could refer to instances where females had been attacked.

Dr. ANDREW CLARK described the cases as model cases admirably recorded, and considered them an important contribution to the study of diseases implicating anatomical units, or separate tissues, the importance of which kind of investigation was very great.

Dr. FOWLER could not refer to any instances in which females had been affected. The tendency to the disease was inherited, and was transmitted in the ovum; it usually affects males, but sometimes females also suffer. The enlargement was due to fatty deposits. Atrophy preceded hypertrophy, as shown by records in which the size of limbs ultimately affected had been registered.

ACADEMY OF MEDICINE IN IRELAND. MEDICAL SECTION.

A MEETING of the Medical Section was held on Friday evening, 16th February, at the College of Physicians, Dr. WILLIAM MOORE, President of the College, in the chair.

EXHIBITION OF LIVING SPECIMENS.

Dr. H. C. TWERDY exhibited two cases of locomotor ataxy.

SPECIMENS EXHIBITED BY CARD.

Dr. G. F. DUFFY showed a specimen of Farre's tubercle of the liver; Dr. J. W. MOORE, a specimen of pulmonary tuberculosis in a girl, *æt.* 12, with secondary infection of the intestines; Dr. LENTAIGNE, a specimen of ulceration and perforation of the intestines, with microscopical sections by Dr. SCOTT; and Dr. REDMOND a specimen of Bright's disease of the kidneys complicated by peritonitis.

THE PRESIDENT OF THE ACADEMY.

Dr. BANKS, President of the Academy, who, owing to domestic reasons, had been unable to attend any of the earlier meetings, expressed his gratification at having been elected President, and said to be well thought of by one's fellows, especially by one's brethren in the profession, was of the greatest satisfaction. He had no words to express adequately his acknowledgments. Indeed, he might say in the words of the poet—

"What can idle words avail
Unless the heart can speak?"

SUDDEN CHANGE IN THE COLOUR OF THE HAIR AND SKIN.

Dr. W. J. SMYLY read a paper on sudden change in the colour of the hair of an infant. The child was perfectly healthy to all appearance until he was four months old. He was then attacked with acute inflammation, followed by suppuration in the left temporal bone, the symptoms being pain, heat, and swelling about the temporal region, with high fever and profuse perspiration; paralysis of the left side of the face, with exophthalmos and of the soft palate. One morning (1st November last) the hair on the right side of the head was discovered to have undergone a remarkable change from its original mouse-coloured hue to a reddish yellow. The right eyebrow was similarly affected, and the skin of these parts as well as that of the right hand was icteric. The pillow also was saturated with a reddish-yellow perspiration. The abscess, which had formed very slowly, pointed behind the ear, was evacuated by a free incision.

Although the child subsequently became hemiplegic, it made a fairly good recovery. The suggestion offered as to the possible cause of this remarkable change of the colour of the hair was that the perspiration, which was of a peculiar colour, and probably of abnormal chemical constitution, not only destroyed the original pigment, but also dyed the hair a reddish-yellow colour.

Dr. BANKS referred to a case which had come under his notice, that of a young woman: half of the lashes of one of her eyes became snow white, which she attributed to the annoyance suffered from the persistent gaze of a "wall-eyed" admirer who had white lashes on the defective eye.

Dr. WALTER SMITH related the case of a boy in whom the skin of the lobes of both ears and that of the back of the neck was of a sulphur yellow, the downy hair being of a bright yellow, while the hair of the head was brown. The yellow colouring could be readily removed by a moistened cloth, but no washing could decolourise the skin; nor did either of chloroform produce any effect. He exhibited specimen of the hair. He also referred to a case of red discolouration recorded by Wilson. After relating the case described by Darwin, in which the hair of a criminal brought out for execution turned white in the presence of the spectators, he said he could not agree with Dr. Smyly in ascribing bleaching properties to the perspiration, but did not give any explanation in lieu of it.

Dr. CHARLES MOORE, Mr. LENTAIGNE, the PRESIDENT, and Dr. GRIMSHAW also joined in the discussion. Dr. Smyly did not reply.

LOCOMOTOR ATAXY.

Dr. H. C. TWEEDY read a paper on two cases of locomotor ataxy, and exhibited the patients. The first case was that of a pensioner, æt. 64, who was admitted into Steevens' Hospital in 1871, presenting most of the symptoms of the affection—the peculiar gait, the absence of co-ordination of the neuralgic pains characteristic of the earlier stages of the disease. He was persistently treated with nitrate of silver, in doses of 1-3rd gr. three times daily, and continued the use of the drug at intervals for nearly twelve years, during which time he was again in hospital during the years 1873-6-82. The ataxic symptoms had completely disappeared, but from the length of time the silver had been taken the patient had become argyrised. Attention was invited to the peculiar leaden discolouration of the skin from this cause, and the opinion of the members was requested as to whether the symptoms clearly indicated a case of tabes dorsalis, or one of those rare cases in which the progress of the disease had been arrested, and a cure had followed, whether spontaneously or the result of the remedy employed. The second case was that of an engine-driver, æt. 42, in whom the disease was only of six months' standing. This patient also exhibited most of the phenomena of the earlier stage of the disease, the peculiar gait, and furfurant pains along the course of certain nerves; but in addition there were consecutive attacks of a cutaneous eruption resembling erythema, entirely confined to the left side of the body, and unaccompanied by any of the usually attendant neuralgic pains. There was also a patch of an eruption resembling psoriasis on the back of the left wrist; no similar patch co-existing at the opposite side. Attention was drawn to the fact of eruptions, usually bilateral, appearing only on one side of the body, the connection between these and similar eruptions occurring as trophic lesions in tabes dorsalis, but accompanied invariably by lancinating pain along the course of the nerves over which the eruptions were found.

Dr. BANKS, having seen a great many cases of locomotor ataxy, was of opinion that in a considerable number the disease stood still, and in others appeared to be removed. He had used nitrate of silver with great advantage, and did not participate in the terror some had of its effects in producing discolouration of the skin. He had once seen it occur in a case of epilepsy. He believed in the existence of a syphilitic taint in a large proportion of cases.

Dr. GRIMSHAW remembered the case brought forward by Dr. Tweedy. The result of the treatment was admirable.

Dr. NIXON agreed with Dr. Banks as to the frequency of arrest, and even occasional cure, of the disease, especially in cases in which syphilis existed. He considered the skin affections in one of Dr. Tweedy's cases as coincidences, and preferred referring them to a syphilitic origin.

Dr. ROBINSON asked whether either of the patients was addicted to the abuse of stimulants?

Mr. LENTAIGNE mentioned a case in which Langenbach

stretched the sciatic nerve, and the symptoms disappeared. A subsequent autopsy showed the spinal cord to be perfectly healthy.

The PRESIDENT related a case of syphilitic origin which recovered under the use of KI.

Dr. HENRY KENNEDY and Dr. W. G. SMITH also took part in the discussion.

Dr. TWEEDY, in replying, said that in the case which had recovered the man had no syphilitic history. Neither patient had been addicted to intemperance.

ULCERATION AND PERFORATION OF THE INTESTINES.

Mr. LENTAIGNE read a paper on a case of ulceration and perforation of the intestines, which was remarkable on account of the great obscurity of the symptoms. It was that of a man æt. 30, who had been admitted into Jervis Street Hospital, 6th December last, complaining of cough and debility, and who died there December 19 from peritonitis consequent on perforation of the intestines. After his admission he had been carefully examined by Dr. MacSwiney, physician on duty; but no evidences of organic disease could be found. Both pulse and temperature were perfectly normal, and the lungs apparently sound. After a few days, the man asked leave to go home, feeling perfectly well; but on December 11, on leaving the water-closet, he was suddenly attacked with all the symptoms of acute intestinal obstruction. These continued unabated until the 14th, when his bowels were freely moved by enemata, after which he had four free motions, passing large quantities of liquid, yellowish-brown fæces. Next day he seemed better, the pain having ceased, and the vomiting only occurring after long intervals. The ejected matters consisted of recently-administered food. On the following day all the severer symptoms returned, and the man died on the 19th, eight days after the inception of the symptoms from obstruction. At the post-mortem examination, besides the usual signs of recent general peritonitis, there was found a large collection of purulent putrid matter occupying that part of the peritoneal cavity which lay in the right inguinal region, the right half of the hypogastric region, and the cavity of the true pelvis. It was apparently localised by the matter of the intestines. On removing the viscera, the pleura was found to be ulcerated in its lower part, and the perforation had taken place through the floor of one of the ulcers. It was situated in one of the coils forming the boundary of the pus-containing cavity, and was apparently sealed up by adhesive inflammation of the peritoneal coat. The spleen and mesenteric glands were enlarged. The lungs were apparently healthy. There was no ulceration anywhere else but in the lowest thirty inches of the pleura. He believed the case to be either one of typhoid fever or of ulceration as the result of a previous attack of typhoid; and he drew attention to the great tenderness and pain over the thyroid foramen, and for a few inches below Poupart's ligament, or the inner aspect of the thigh—a condition which, when coupled with the symptoms of intestinal obstruction, might easily lead to a mistaken diagnosis of obturator hernia, due to pressure or inflammation of the obturator nerves before their exit from the thyroid foramen.

Dr. MACSWINEY said that when the patient in the early stages of his illness was under his care, he did not present any symptoms of typhoid fever.

Dr. C. NIXON insisted on the importance of splenic enlargement in the diagnosis of typhoid fever.

Dr. J. W. MOORE said that constipation in those cases was a most unfavourable symptom. Perforation was sometimes produced by over-distension of the intestines, consequent on the formation of gases by the decomposing fæcal matter. The patient, he considered, had passed through typhoid fever before his admission to hospital.

Mr. LENTAIGNE, in replying, agreed with Dr. J. W. Moore that the case was one in which the typhoid had been passed through, and that the perforation was the result of necrosis, a sequela of the fever.

The Section then adjourned.

MR. H. HEATHCOTE STATHAM is announced to give the first of two lectures on "Music as a Form of Artistic Expression," at the Royal Institution, on Saturday, March 10, and Professor Tyndall one on Friday evening, March 16, on "Thoughts on Radiation—Theoretical and Practical."

France

[FROM OUR SPECIAL CORRESPONDENT.]

PARTICULAR FORM OF GUN-SHOT WOUNDS.—M. Jules Guérin communicated to the Academie de Médecine a note on a particular form of gunshot wounds, in which the projectile, on entering, ran a certain distance in the tissues before making its exit (*plaies en sillon*). The veteran professor went very minutely into his subject, and gave the treatment which he considered best applicable to this kind of wound, and which consisted in washing out the wound antiseptically by a continued current effected by an india-rubber tube, of which one end is fixed in the wound while the other is plunged into a basin filled with an antiseptic solution. His reflections were no doubt suggested by the wound which caused, although indirectly, the death of the great republican.

HYPOGASTRIC LITHOTOMY.—At the Société de Chirurgie M. Monod read a paper on abdominal, or more strictly, hypogastric lithotomy. Three times he practised the operation, and of the three patients but one succumbed. The first case was that of a man, *æt.* 56, who, in his youth, underwent the operation of lithotripsy, which was very successfully performed, and for years he had no further trouble in the urinary organs. However, for some time before his admission into hospital in August last, all the symptoms of stone returned; and having rapidly increased in gravity, he decided on placing himself under the care of M. Monod, who, on examination, found the calculus to be voluminous. Lithotripsy being recognised impossible, the already eminent surgeon, after dilating the bladder by means of a large injection of water containing boric acid, and its displacement forwards by distension of the rectum, proceeded to cut down on the stone a little above the pubis. The bladder reached, it was found that the calculus was encysted, and intimately connected to the walls of the urinary receptacle, so that it was with great difficulty the foreign body was detached, and not until the adhesions were broken down and the stone fractured into four pieces. The bladder was then washed out with a current of water and two drainage-tubes placed. During the whole time of the operation the *cul-de-sac* of the peritoneum was kept pushed back, so that it in no way interfered with the operator. The cure, though a slow one, was, nevertheless, very satisfactory, and M. Monod congratulated himself that he did not attempt perineal lithotomy, which, under the actual and revealed circumstances of the case, would have presented greater difficulties and been attended with considerable danger. The second case was that of a man, *æt.* 67. The operation was practised in the same manner—dilatation of the bladder, distension of the rectum by means of an air-bag, lithotomy above the pubis, extraction of the calculus, and drainage. The results were not satisfactory; from the outset the patient showed bad symptoms, and he succumbed on the fifth day. The third case was that of a young man, *æt.* 28, who had a calculus since his youth. Lithotripsy was tried, but failed from the extreme hardness of the stone. The bladder was being distended by an injection of the same solution as in the other cases, when it suddenly gave way under the pressure, to the no little consternation of all present. After some hesitation as to the conduct to be followed, the intrepid operator decided on continuing, and the operation was completed with facility. Although the bladder was ruptured, the cure was no less satisfactory as in the first case. In

concluding his remarks, M. Monod said that the operation had been performed in sixteen cases, of which eleven were successful. M. Verneuil said he practised the operation himself in a very unfavourable case, and yet with complete success. It was that of a man with double hernia, very voluminous, and a very large prostate and a kidney affection. M. Verneuil, after extracting the stone, sutured the bladder which gave him some trouble, so that in future he was determined in these cases to renounce sutures. Several other members followed, expressing themselves as favourable to the operation in question.

MATERIA MEDICA: ITS POSITION AS A BRANCH OF THE ART OF MEDICINE.

In medicine, as in everything else, "the middle course is the safest," is a good and safe proverb to remember. Over-drugging is certainly an evil, but equally so is scepticism in the use of drugs. It is easy to scoff, and sneer, at those who have faith in the remedies they use, and to ask for a *rationale*, as yet perhaps not thoroughly understood, as to the manner in which a drug effects the purpose for which it is given, but observation teaches that those men are the most successful in the results obtained in their practice, who have faith in the remedies they use, and who do not prescribe them as a mere matter of routine, but

who, having a definite object in view, give them with due consideration, and watch and note their effects with keen interest. Such men have an unceasing, and continually increasing interest in their profession, and are prepared to fight to the end for the life entrusted to their care, with a zeal that cannot be experienced by those who are not possessed of the same faith, and who practically are mere believers in the doctrine of the survival of the fittest. Whilst freely admitting, that much has been done, and that much good is likely to be accomplished, by "preventive or hygienic" medicine; all the good, that is anticipated by enthusiasts in that branch of our art, is not likely to be attained,—at least, not until the millenium arrives. It is hard to believe in the perfectability of the human race. So long as men exist, so long is it likely that there will be disease, and so long as there is disease, so long will the necessity for the use of drugs continue, and *materia medica*, in its therapeutic sense, will hold an honoured place as a branch of the art of medicine. In his address to the members of the "Medical Union Society" of London, Dr. Richardson has used an expression, the interpretation of which is open to some doubt as to its real meaning. Speaking hopefully of the preventive side of medicine, and rightly so, he says, "*Materia medica* must also grow of less importance, for presently all men would become wise in their estimate of drugs, and would call for them as reluctantly as the members of the profession did themselves when they were out of health." Do medical men at present refrain in their own cases from the use of drugs, *because* they disbelieve in their efficacy. If such be the case, the standard of professional honesty and morality must be a low one, representing men as capable of prescribing for others, things in which they themselves have no faith, and which, since they are known to possess some active qualities, must, if not beneficial, be positively injurious to their patients. The only justification a man can have for administering to any one a drug is his belief in its likelihood to prove of service. Unbelievers in the efficacy of medicine should have the courage of their opinions. They should honestly tell their patients they have little or no faith in medicines, and, above all, they should carefully record and publish for the guidance of others the results of their practice. Once let it be seen clearly that all diseases have a fixed course, unchecked, or unaltered by treatment, and a grave responsibility will be removed from the shoulders of the members of the profession, and their task be made an easy one. This consummation has not as yet been arrived at, nor is it likely to be so at an early date.

By all means place people in healthy surroundings, and educate them in all the rules that are necessary to the preservation of a healthy life, but do not cast any reflections upon the means by which health is to be restored when diseased action is once set up. The enlightened use of drugs is surely one of those beaten paths "laid down in the grand old history of medicine," from which his hearers ought to have been warned not lightly to depart, or to think slightly of; the rather, ought they to have been urged to zeal and industry in the exact observation of the effects of drugs,

and the exact record of the conditions which lead to their exhibition, and the effects that were expected from their use. Such study would go far, if honestly pursued, to place the art of prescribing on a sound foundation. All must admit that much solid work has been accomplished in this direction; our knowledge of the action of many drugs is as definite as we can reasonably expect it to be, if we take into consideration the peculiar idiosyncrasies, that are occasionally to be found in different constitutions, and which set at defiance all our previously acquired experience, and which are unrecognisable until discovered by the test of experiment. Whilst readily admitting that in many instances there is a tendency to cure on the part of the natural powers of the body, still, Nature, if left to herself, does not always prove a successful physician, and is often glad of a little help to get her out of a difficulty, and to re-establish the balance of power amongst the various organs of the body. Without the help of our art, excitement, and pain, remain unsoothed or unrelieved, or there is failure on the part of the excretory organs to remove the waste products of the body when diseased action has taken place. Collective work, and the severe habits of observation and deductive reasoning that such work is likely to foster, will do much to bring forward a vast amount of evidence on such points as these, and, in time, much, that is at present a scattered and floating kind of clinical experience, will be brought together and crystallised into definite knowledge.

Certainly he who has not faith, and does not use in the spirit of faith, properly guided by careful consideration, and an ever-increasing experience, opium, ipecacuanha, mercury, arsenic, antimony, ergot, iron, zinc, phosphorus, bismuth, and their preparations, chloral, croton chloral, aconite, belladonna, *sp. eth. nitrosi*, *sp. eth. sulphurici*, quinine, iodide, and bromide of potassium, and many other drugs, can never be a thoroughly successful practitioner in the curative results of his practice; nor can we believe him to be a happy one, if possessed of a conscience, since he must see many cases—that in other hands might do well—go from bad to worse, and end fatally in his.

Many men doubt the efficacy of drugs because their efforts have not been attended by success; but this want of success is more often not the fault of the remedies themselves, but the fault of the prescriber, who fails, from the want of an almost intuitive tact, in the selection of the best drug, or drugs, and in their proper combination, and dosage. How frequently one sees a patient, who, under the treatment of one man, drags on wearily from week to week, no better—often, indeed, going from bad to worse,—under another man's care rapidly improve, and from the very rapidity of recovery, giving proof of the efficacy of the drugs employed. Instead of lowering the estimation in which our *materia medica* is held, increased knowledge is likely to carry it to a still more honoured position, when the powers of each drug, from accurate observation, become more thoroughly defined.

PROFESSOR SAYRE, we regret to learn, is dangerously ill,

FOUNDATIONS FOR DEATH.

DURING the past week the old question of infection-breeding foundations has once more been raised, this time in a court of law, and with the result—scarcely a novel one, it must be confessed—that a parish vestry stands revealed as countenancing the vicious system which leads to such frequent dire consequences. In the case referred to a resident in Fulham, living near a vacant piece of ground known as “Dancer’s Land,” sought to restrain the defendant from depositing on the land any solid or liquid refuse so as to occasion a nuisance. For the defence it was urged that permission had been accorded to the defendant by the Fulham Vestry to deposit such rubbish in places whence he had removed the clay and gravel, for the purchase of which a contract had been entered into with the parochial authorities. Mr. Justice Fry, in giving judgment for the plaintiff, commented severely on the evils likely to be perpetrated so long as proceedings of which the defendant had been guilty were permitted, and the importance of the matter is so great that too much attention cannot be paid to it in the public interest.

At the present time building operations are rapidly progressing in every direction on the outskirts of London; and the demand for houses at moderate rentals is so great that contractors for the erection of this class of property naturally employ every device for securing to themselves the fullest advantages the demand will permit. To this end they excavate the “eligible plots of building land,” and sell the clay and gravel or sand so removed, and the vacancies thus formed are in almost every instance refilled by means of such assistance as can be lent by those who are always on the look-out for the legend, “Rubbish may be shot here.” Unfortunately, there is no sort of supervision exercised as to the quality of the rubbish so invited; quantity is the first and foremost element considered; and the consequence is that houses innumerable are at this moment standing on foundations consisting mostly of decomposing garbage, house refuse, and the indescribable compound that goes to fill the ordinary domestic dust-bin. Some time, it will, by-and-bye, occur that atmospheric conditions favourable to development of influences antagonistic to human life will educe the harmful products thus ruthlessly encouraged by a short-sighted Government, and mysterious recurring epidemics will exercise the ingenuity of hygeists to account for their mode of origin. What is known as “Kensington sore throat,” a malady before which we have known immigrants into the “fashionable suburb” quickly succumb, might not improbably be successfully eradicated could the foundations, on which the costly “mansions in flats” are built be replaced with healthy and cleanly mother-earth. The whole subject, however, can only be dealt with under the highest authority, and it cannot be too speedily so investigated.

THE preservative injection of Dr. Tounletti, by which animal bodies may be preserved in a fresh state for an unlimited time, has been found perfectly successful, but its composition is still a secret.

“HAVE PARLIAMENT OR THE PUBLIC SANCTIONED COMPULSORY NOTIFICATION?”

THE assent given by the House of Commons’ Select Committee of last year to the passing of the eight private Bills submitted to them, each Bill containing provisions for compulsory notification by the physician, has been heralded by the advocates of a general notification law as a conclusive parliamentary decision in favour of their cause, and abundant use has also been made of the fact that twenty-two town councils have obtained the power to force the physician to notify without any serious opposition on the part of the medical profession. As both of these statements are disingenuous and calculated to convey a false impression, it is necessary for us to state the truth of the matter, lest physician notification may come to be regarded as a foregone conclusion.

In the first place it is a fact that compulsory notification has *never yet been discussed in Parliament* at all, nor has any opportunity ever occurred for submitting the proposed law to legislative criticism. In each and every case the notification clauses have been schemed through the House of Commons concealed amongst a mass of local regulations for the making of roads, laying down of water, or gas pipes, or other civic improvements in which no one takes the least interest, and very few have the least knowledge, save the Corporate officials of the town to which they apply. The usual method of “dodging” a bill of this sort through the house is too familiar to need a detailed description. It is drafted so as to arouse as little suspicion or opposition as possible, and the money interest of all parties who might throw difficulties in the way is “squared” quietly beforehand; the Town Surveyor contributes his clauses, the Town Clerk his, the Medical Officer of Health his, and the Bill is glanced over by half a dozen of the Town Councillors in committee. Then the necessary parliamentary notice is given by advertisement, and care is taken to hide it away in the columns of local newspapers which are not likely to be read, and which are known to be friendly to the cause. The standing orders of Parliament, however, provide that, in case the costs of promoting the Bill are to be paid out of the Borough funds, it must be submitted for approval to a public meeting of ratepayers. In the majority of cases this meeting means nothing; it is planned so as to go off smoothly, and generally is a mere matter of form, but wherever anything in the way of serious opposition is expected, the difficulty is got over by the Town Council paying the promotion costs out of some other fund than the Borough fund, and thus dispensing with the public meeting altogether. The stage of drafting, advertising, and public meeting being got over, the Bill is ready for introduction to the house. It is usually kept back until the fag end of the session, and, at length, laid on the table of the House and read a first time at cock-crow on a summer’s morning when half the members are gone off to travel, or to prepare for grouse shooting. If unopposed, it is not even read through by anyone, and in a few days the local public and the medical practitioners are officially informed that a new law to bind them has been passed—that the Town Council, by its authority, has made a sheaf of new

regulations, and that, as it is now too late to object, they must either obey or go to goal. That this method of procedure is in substance the one which has been hitherto pursued with reference to compulsory notification is proved by an examination of the answers given by Town Clerks to the question put by the English Local Government Board, whether "before the powers contained in these provisions were obtained, public attention was specially directed to the intention of the local authority to apply for them?"

It is admitted that in Birkenhead, Blackburn, Lancaster, Preston, and Stafford no public notice in any form was given. Norwich, Blackpool, and Rotherham make no reply, and may, therefore, be assumed to have no affirmative answer to give. The other towns answer simply "Yes;" but when we turn to the detailed replies given by the Town Clerks we find that what they call public notice was nothing more than the formal Parliamentary advertisement to which we have above referred, no public discussion of the subject having taken place. This is true of Barrow, Blackburn, Bolton, Derby, Reading; and Stalybridge, Llandudno, Manchester, Oldham, Jarrow, and Burton give indefinite replies, and do not state that any public discussion of the subject ever took place.

In Warrington, a public discussion of the proposed Bill did take place; but the Town Clerk states that that discussion had reference only to gas clauses, and that the notification clauses were not considered. In Leicester the medical practitioners memorialised the mayor to afford an opportunity for considering the proposed law, but they were refused any facility for doing so. In Bradford, Huddersfield, Greenock, and Nottingham the medical profession got wind of the intentions of the corporation, and, by vigorous agitation, succeeded in defeating many of the provisions of the proposed law and modifying others.

The case of Edinburgh is illustrative of the method which the compulsionists pursued to obtain the assent and co-operation of the medical profession, of which they now boast. In that city the corporation went honestly to work, and circulated their proposals largely. The immediate result is stated, as follows, by Dr. Littlejohn, the Medical Officer of Health, in his report:—

"Both Colleges (of Physicians and Surgeons) reported against the proposal, and stated that they would oppose in Parliament any Bill which contained the clause in question. This was somewhat discouraging, but so convinced was the corporation of some such enactment being absolutely requisite to prevent the spread of epidemic disease that they introduced into their proposed Police Act a clause rendering it imperative on all practitioners within the burgh to report, and the Bill passed."

The truth of the matter, as stated, on Dr. Littlejohn's authority, at the Dublin meeting of the Social Science Congress, is that when the Corporation of Edinburgh found that the feeling of the profession was dead against compulsory notification, they withdrew the proposal for the time being, and when, by this means, they had lulled the profession into a sense of security, they allowed Dr. Littlejohn to alip the objectionable clauses into a quiet little local Bill, which was got through Parliament

while the Colleges slept. Dr. Littlejohn is stated to have boasted that he managed to put the profession off their guard by refraining from going to London to promote the Bill, and that the Colleges knew nothing of the matter until it was too late for them to resist.

With these facts before us, we feel ourselves fully justified in characterising as totally false the assertion that either the public or Parliament have given any assent to the principle or practice of compulsory notification by the physician; and we assert, without hesitation, that the law on this subject has been obtained by corporate trickery, and by hoodwinking Parliament, under the pretence that the Bills containing that law were mere unopposed local and private measures.

Notes on Current Topics.

The Medical Union Society.

THE Medical Union Society appears to be making steady progress, and to have set out on the path of usefulness sketched out in its preliminary announcements. A large gathering of members took place on Saturday evening last at the rooms of the Union, 10 Adelphi Terrace, W.C., the occasion being a debate on "The Plea of Insanity in Criminal Cases." Dr. L. S. Forbes Winslow opened the discussion, and submitted a resolution in favour of appointing medical assessors, by whom the condition of criminals condemned to death should be examined, and by whom the question whether or not the prisoner is of unsound mind should be decided. A well-sustained debate was carried on for more than two hours, a large number of student members of the Society engaging in it; and ultimately the motion was carried, after one or two amendments had been put and lost. The success of the meetings for debate, which with one exception have all been well attended, affords ample proof that students are willing to avail themselves of *bona fide* opportunities of combining instruction with relaxation. The institution of these debating meetings is almost the happiest outcome that has yet attended the Society's efforts; and we sincerely hope that so valuable a means of intellectual recreation may be assiduously cultivated.

Re Advertising.

At the present moment, when the Royal College of Physicians of London is believed by more trustful members of the profession to be debating how best to give effect to its desires on the subject of Advertisers, it may not be improper to recommend to its notice such infringers of the "resolution" as have substantiated a claim to immediate consideration. Among these is a gentleman who has for some time requested the public to "shut its mouth" through the agency of a penny pamphlet, on the title-page of which the author of the mouth-shutter carefully prints his name and the following qualifications—M.D., M.R.C.P. Lond., M.R.C.S. There is also appended beneath the "price one penny," which relieves the author of any suspicion of charitableness—and thus possibly enables him to smile at the "College's" restrictions—the following most ingenious legend: "The

profits of the sale of this pamphlet will be given to the Dispensary for Deafness and Affections of the Speech.' As the College is apparently not always conversant with the ways of its licensed advertisers, it may be well to add that "Shut your Mouth" contains a page advertisement of the no doubt admirable Dispensary for Deafness and Affected Speech to which its author's invaluable services are given. Announcements also of Keen's mustard, Fry's cocoa, and other useful and nutritious articles of food are, however, held forth to the perusal of readers of "Shut your Mouth," the spirit of which command will not, we trust, be discernible in the expected action by which the Royal College of Physicians is supposed to be about to vindicate its pretensions.

Another point might also not inappropriately be considered, namely, that to which a correspondent draw attention in our present issue, dealing with the advertising by the College itself of "Lectures on Sterility in Woman" in the columns of the lay press.

Prof. Flower's Lectures.

THE annual course of lectures by Prof. Flower, delivered at the Royal College of Surgeons, will this year be on "The Anatomy of the Horse and its Allies." The course commenced on Monday last, and will be continued each Monday, Wednesday, and Friday succeeding for three weeks. The following syllabus of the nine lectures has been issued:—Lecture I. Position of the Horse in the Animal Kingdom. Classification of the Mammalia. The *Ungulata* or Hoofed Mammals. Generalised forms, mostly extinct. Characters of the two principal surviving groups—the *Perissodactyla* and *Artiodactyla*.—Lecture II., Wednesday, February 28th. The perissodactyle or "Odd-toed" Ungulates. Characters of the existing species of *Tapirida*, *Rhinocerotida*, and *Equida*. Lecture III., Friday, March 2nd. Extinct species of Perissodactyles. Generalised forms. Forms closely related, or which lead up to existing forms. Forms which have become specialised without leaving descendants or representatives.—Lecture IV., Monday, March 5th. Anatomical characters of the Horse in further detail, and as compared (a) with the generalised Mammalian type, (b) with the allied forms of Ungulates, and (c) with Man. The Skeleton.—Lecture V., Wednesday, March 7th. The Dentition.—Lecture VI., Friday, March 9th. The Muscles. Structure of the limbs, especially of the feet.—Lecture VII., Monday, March 12th. The Brain and Organs of the Senses.—Lecture VIII., Wednesday, March 14th. The Respiratory, Circulatory, Digestive Systems, &c.—Lecture IX., Friday, March 16th. Recapitulation and Conclusion.

DR. CHARLES M'DONALL, formerly Professor of Greek in Queen's College, Belfast, died at his residence in that town on Sunday last. He was born near Edinburgh in 1813, and in 1847 was appointed Professor of Hebrew and Oriental Literature in Edinburgh in succession to Professor Brunton. He resigned in 1848, and in the following year was appointed to the Chair of Greek in Queen's College, Belfast, which he held until a few years since, when he retired in consequence of loss of eyesight.

Surgical Appliance Society.

AT the tenth annual meeting of the Provident Surgical Appliance Society, held last week at the Cannon Street Hotel, the secretary read a satisfactory report of the year's work of the Society. There was, however, a balance against it of nearly £190. The office is kept open until seven o'clock p.m., and a surgeon attends twice daily—in the morning and evening. During the year the Society had distributed an increased number of surgical appliances—upwards of 3,000—which augmented the total since the foundation of the institution to 24,719. It was now able to provide an artificial arm and hand at a cost not exceeding 30s., and an artificial leg and foot at a cost not exceeding 50s. These limbs have been procured from France, where they have been used and appreciated for some years on account of their being lighter than, and equal in durability and usefulness to, the more expensive cork leg.

The Royal Barracks, Dublin.

LAST week, Lord Hartington, in reply to a question by Mr. A. O'Connor, stated in the House of Commons that on November 30th last the Lord Lieutenant drew the attention of the War Office to rumours that cases of typhoid fever among the troops in Dublin were attributable to the insanitary condition of the Royal Barracks. A full inquiry was at once made, and it was found that there had been two cases of typhoid fever at the barracks. The principal medical officer considered them as part of a general outbreak of typhoid fever in Dublin, rather than the result of any special defect in the Royal Barracks. No positive sanitary defects could be found in the barrack drains; but steps were taken to secure more perfect ventilation.

The Medical Reform Bill.

BOTH Lord Granville and Lord Hartington have promised that the Government Bill will be introduced before Easter, and as that epoch occurs on the third week in March, we shall probably have the measure in hand within the next ten days. We hope that within that period all reformers will make their preparations for a great effort in support of its principle (assuming that it will be framed on the Royal Commission's Report).

It will, of course, need many minor amendments, and every one will be at liberty to fight for these when the time comes, but what every reformer must put out his strength to do is to defeat the solid opposition of the General Medical Council and the Scotch licensing bodies, who will resist any or every sort of reform by any or every means. This opposition will have to be met on the second reading of the Bill in the Lords, and again at the same stage in the Commons, and it will, no doubt, be carried to the verge of obstruction, when the Bill gets into committee, in the hope that the measure may be pushed over to the end of the session and so defeated. This opposition will represent not more than half-a-dozen institutions, and say 150 individual members of our profession; but this handful will be fighting for their pockets and prejudices, and, moreover, will be generalised by strong men. We suppose that Professor Turner will be the leader of the Scotch onslaught, and Mr. Simon, his ally, in charge of the Medical Council forces. If the medical reformers do

not meet and overwhelm this forlorn hope, they will certainly deserve to lose the reform, which, ever since 1870, has been almost within their reach. We have no apprehension of such a result. Government seems determined, and the course is fairly clear of legislative encumbrance, so that we have every hope that before next August the days of sham education, Medical Council incompetency, and impunity for quackery will have passed.

Residences for Medical Students.

THE want of suitable residential accommodation for students attending the schools attached to our hospitals is one of the drawbacks which mitigate in various ways against the full measure of success of those institutions which are not favoured with "chambers within college walls." This is particularly so with such an one as the London Hospital, situated as it is in the densest and poorest part of the metropolis, yet having the largest number of students attached, who have to seek the necessary accommodation in remote districts, and at great loss of time and expense. To remedy this grievance, a meeting of the House Committee and Medical Council was held last week for the purpose of discussing the question of providing a resident college for the students connected with the hospital. Mr. J. H. Buxton presided, and explained that the notion had long been in the minds of many interested in the hospital. Dr. Andrew Clark, senior physician, then moved the following resolution:—"That, in the interests of the London Hospital and Medical College, it is expedient that a suitable resident college for students be provided." After referring to the intimate connection between medical and surgical practice and medical and surgical education, and also to the value of the stimulus received by professors and teachers from contact with the younger minds of students, Dr. Clark spoke of the difficulty of managing the increasing number of students owing to the character of the neighbourhood of the hospital, and consequent difficulty in finding suitable lodgings for them, and said the time had come for some effort to provide these students with a place of residence which should give them that unity and solidarity which was desirable for their success. It would also provide for the hospital a certain number of young men always at hand who could be enlisted in the various services required in the hospital, which are now, as regards surgical subjects, somewhat inadequately done. A resolution to the effect—"That a committee be appointed to inquire into the best method of carrying out the above resolution, and to report to a subsequent meeting at an early date"—was then carried unanimously, and the said committee was nominated. It was understood that the carrying out of the scheme was in no way to interfere with the funds of the hospital, as the money would be obtained either by the formation of a company or by some other suitable means.

WE learn by telegram that five insane persons in the Asylum at Staunton, United States, have died almost instantly after taking their morning medicine, which, it is believed, a lunatic poisoned. Throughout the whole institution a painful terror was created.

Compulsory Notification put to the Test.

THE advocates of compulsory notification have persistently filled the ears of the public with the assertion that, wherever it has been tried, that system has been productive of the most beneficent result on the public health, and by dint of repetition has caused this statement to be taken for granted by many. It is, however, not only totally unproved, but, we believe, absolutely untrue, and of this fact anyone may satisfy himself who pleases to peruse a pamphlet just issued by Holden, 48 Church Street, Liverpool, or Hodges, Grafton Street, Dublin, on behalf of Dr. Hamilton, Senior Surgeon of the Liverpool Southern Hospital, and a member of the Health Committee of the Liverpool Corporation. That Committee, not being content with the gushingly laudatory reports which it received from various medical officers of health, sent a deputation, of whom Dr. Hamilton was one, to eight selected towns to investigate the working of the system therein. The deputation wrote in advance to the town clerks asking them to summon those representative medical practitioners who might be able to throw light on the subject; but as the town clerks carefully omitted to do so, the deputation was obliged to take that evidence on its own behalf. The fact was then disclosed that in these towns, where, according to the account given by the medical officers of health, all was harmony, sanitary enthusiasm, and blissful immunity from disease, there really existed acrimony, concealment of infection, and undiminished mortality from infectious ailments. Dr. Hamilton does not confine himself to assertion; he proves the failure of the notification system out of the mouths of the medical officers of health themselves, and other most creditable witnesses, and in the case of each particular town is enabled to give a contradiction amounting to the lie direct to the audacious assertions of the sanitary enthusiasts. We invite the sceptical to read and learn, and, when they have done so, to refrain from repeating the discredited assertions which have been heretofore put forward by them as uncontradicted, but which are now flatly denied and conclusively disproved.

Medical Education on the American Model.

IN the recent debate on medical reform in Dublin, the chief speaker against reform quoted America as a model country, where free trade in medical education, and consequent rapidity of scientific progress, was manifested. Probably most of the speaker's auditors were not familiar with the condition of things thus held up for their admiration and imitation. The following extract from the evidence given by Dr. Billings, probably the greatest authority in America on such a subject, before the Royal Commission, will serve to enlighten our readers on the educational advantages which they might expect from the maintenance of multitudinous licensing portals and free trade in practice in our country. Dr. Billings was asked: "Is it your opinion that any American graduate before being allowed to register in Great Britain should be required to submit his degree, &c., to the General Medical Council; and that that body should inquire into the character of the examination which he had undergone?—It would be rather difficult, I fancy, for the General

Medical Council to inquire into the character of the examinations of the American schools. There are a great many of them, and of all grades, and in the majority of the States any three, or four, or five men who choose to associate themselves together and expend a very small amount of money (£15 or £20, perhaps, paid to a lawyer to conduct the matter), can obtain a charter from the State, which will empower them to act as a medical school, and confer the degree of doctor of medicine.

The Profession at the Levee.

At the Levee held last week at St. James's Palace by H.R.H. the Prince of Wales, on behalf of the Queen, the following members of the profession had the honour of being presented:—Dr. Arthur Farre, Dr. Sieveking, Dr. Owen Rees, Dr. P. H. Watson, Dr. Clement Godson, Dr. T. J. MacLagan, Dr. T. B. Crosby, Dr. Douglas Lithgow, Dr. Dalzel, Dr. Laking, and Dr. Reginald Read; Mr. Francis Mason and Mr. Borlase Childs; Deputy Inspector-General J. Breakey, M.D.; Surgeon-Majors Robert Anderson and F. B. Baker; Surgeons William Campbell, M.B., C. E. Harrison, and Charles P. Turner; Fleet Surgeons B. Ninnis, M.D., and Alexander Turnbull, M.D.

Medical Appointments for India.

In the House of Commons last week Mr. Gibson asked the Secretary of State for War whether the medical appointees in the Army, Navy, and in India had to give their names and qualifications to the Board of Examiners instead of being known to the examiners by numbers only, as in almost all other public examinations; whether there was any member of the Board of Examiners with an Irish qualification, or having any connection with Ireland; and whether, having regard to the dissatisfaction and discontent which existed among Irish candidates as to the results of the recent examinations, he would either have Ireland represented on the Board of Examiners, or else take care that the candidates should only be known to the examiners by numbers. Lord Hartington said one of the examiners was a Dublin member of Parliament. He would consider the desirability of substituting numbers for names.

Mr. Benjamin Banks.

THIS gentleman, the well-known and much-esteemed Secretary to the Irish Local Government Board, has, after many years of official service, retired. Mr. Banks had, perhaps, the longest standing of any high-placed official in Ireland. He was Chief Clerk of the old Poor-law Board, not only for years but for decades of years, and as such his name appended to documents in the union boards of the country became familiar as household words. Before his Irish appointment he had been in a Governmental clerkship in England, of which country he is a native, and whence he was transferred to Ireland. Always at his post, his experience was invaluable to the board. On the formation of, or rather change of name to the Local Government Board, Mr. Banks became its first Secretary, the duties of which post he has discharged for more than ten years. The Poor-law guardians throughout Ireland have reason to be indebted to Mr. Banks for his painstaking assiduity in guiding them when they needed

his aid through a labyrinthian code of laws, the mastery of which is a matter of long time and great trouble. Mr. Banks is succeeded by the assistant-secretary, Mr. William D. Wodsworth, a gentleman who has worked in harness with the now retiring secretary for a very considerable period. The new assistant-secretary is Mr. James Brenan.

Dr. H. MacNaughton Jones, of Cork.

At the annual meeting of subscribers to the Cork Ophthalmic and Aural Hospital, held on the 12th inst., a warm vote of thanks to Dr. H. MacNaughton Jones for his services in connection with the hospital was passed, and while expressing sorrow at the loss of his services, the meeting assured him that he had their heartiest wishes for his success in London.

A Counterblast to the Anti-Vivisectionists.

MR. ARTHUR BALFOUR has given notice that on the order for the second reading of the Vivisection Abolition Bill he will move:—"That, while due provision should be made for preventing the infliction of unnecessary pain on animals, it is inexpedient so to limit scientific investigation as to hinder discoveries which must result in a great diminution of human suffering."

Private Lunatic Asylums.

MR. CORBET, M.P. for co. Wicklow, who, before entering Parliament, was chief clerk in the office of the Inspectors of Lunatic Asylums, in Dublin Castle, has got leave to introduce a Bill to amend the law relative to private asylums in Ireland, with a view to making other arrangements for admission of paying patients. Of the terms of the Bill nothing is yet known.

Medical Research Association.

WE are informed that Mr. Watson Cheyne, of King's College, London, has been deputed by the Association for the Advancement of Medicine by Research to proceed to Toulouse and Berlin for the purpose of carrying out a series of investigations on the *bacillus tuberculosis*. This course is rendered necessary by reason of the obstacles to research in this country through the existence of the Anti-Vivisection Act.

THE death-rate in the large towns last week from diseases of the zymotic class was considerably below the average, the highest being—From whooping-cough 1.3 in Wolverhampton and in Nottingham, 1.4 in Halifax, and 4.1 in Hull; from scarlet fever, 1.4 in Sheffield and in Blackburn; and from fever, 1.1 in Preston, 1.4 in Halifax, and 2.9 in Blackburn. The 31 deaths from diphtheria included 14 in London, 6 in Glasgow, 2 in Edinburgh, 2 in Plymouth, 2 in Nottingham, and 2 in Sheffield. Small-pox caused 3 deaths in London, 3 in Birmingham, 2 in Newcastle-upon-Tyne, and one in Sunderland. In Dublin the general death-rate was excessive, the increase being principally from deaths of aged persons and those in public institutions. The excess in Bradford was entirely due to the completion of the inquest on 30 bodies, killed by the fall of a chimney in December last.

St. Thomas's Hospital Paying Wards.

THE success attending the experiment made at St. Thomas's Hospital in the way of opening a ward for the reception of paying patients has been so great as to encourage application for an additional ward. The number of candidates for admission has often exceeded the beds—forty-one—available. That the innovation has conferred great benefits in many ways on the middle classes of society is fully apparent; and though we may be allowed to regret that all the resources of the hospital cannot, for want of funds, be utilised in behalf of the sick poor, it is still a matter for congratulation that its advantages are not confined within the limits its income prescribes.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Birkenhead 15, Brighton 17, Leicester, Oldham, Derby 18, London, Bristol 20, Norwich, Sunderland, Salford, Halifax, Portsmouth, Bolton 21, Edinburgh, Plymouth, Leeds, Cardiff 22, Nottingham, Preston, Birmingham 23, Sheffield, Newcastle-on-Tyne, Bradford 24, Manchester 25, Blackburn, Huddersfield, Wolverhampton 26, Liverpool, Hull 27, Glasgow 29, Dublin 39.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 38, Bombay 30, Madras 33, Paris 28, Geneva 33, Brussels 24, Amsterdam 32, Rotterdam 30, The Hague 23, Copenhagen 24, Stockholm 29, Christiania 15, St. Petersburg 40, Berlin 24, Hamburgh 32, Dresden 24, Breslau 29, Manich 32, Vienna 32, Prague 32, Buda-Pesth 32, Trieste 37, Rome 22, Turin 25, Venice 44, New York 25, Brooklyn 20, Philadelphia 23, Baltimore 32.

Scotland.

FROM OUR NORTHERN CORRESPONDENTS.]

REMARKABLE CASE OF LONGEVITY IN SCOTLAND.—Dr. Charles Stewart, of Larkhall, states relatively to cases of longevity that there at present lives in the town of Larkhall a man whose years now undoubtedly reach 103. His faculties are unimpaired, and he is extremely high-spirited and fond of fun. He works daily, walking a distance of nearly two miles to and from his work each day. He is the father of a considerable progeny, who naturally are people in the decline of life. He never had a day's illness during his long life until about nine months ago, when he had a severe and dangerous attack of a disease peculiar to senility, from which he entirely recovered with surprising rapidity, to the astonishment of his friends and Dr. Stewart, his medical attendant. This highly interesting individual is an Irishman.

TYPHOID FEVER AT BANNOCKBURN.—For some weeks past typhoid fever has been prevalent in the village of Bannockburn, and several cases have proved fatal. The county authorities had no official intimation of the epidemic, but the local police discovered that a woman who kept a dairy had a son and daughter ill with the fever, and that most of the persons affected with the disease had been getting their milk supply from her. The dairy was at once ordered to be closed.

DEATH BY SWALLOWING FALSE TEETH.—A woman residing

in Edinburgh was admitted into the Royal Infirmary on the 17th inst., in consequence of having some hours before swallowed the upper section of a set of artificial teeth. It appeared that the woman got up hurriedly in bed to attend to her child, and in doing so the socket and teeth fell into her throat. An operation was performed during the day, but the woman died about noon the following day.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday the 17th inst. were at the rate of 29 per 1,000 per annum, against 30 in the preceding week, and 28, 29, and 30 in the corresponding periods of 1882, 1881, and 1880.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 17th inst., was 94, and the death-rate 21 per 1,000. Diseases of the chest accounted for 50 deaths, and zymotic causes for 5, of which 1 was due to fever, 1 to scarlatina, and 2 to measles, the intimations of these diseases for the week being 6, 33, and 6.

UNIVERSITY OF ST. ANDREWS.—At a recent meeting of the Privy Council, we understand that Her Majesty was pleased to reappoint for a period of five years, Dr. J. Ball Pettigrew, F.R.S. (Professor of Anatomy and Medicine in the University of St. Andrews), to represent the Universities of St. Andrews and Glasgow in the General Council of Medical Education and Registration in the United Kingdom. Professor Pettigrew has represented these Universities since 1877. If we consider the fact that in 1882 the number of first year's students which entered at St. Andrews amounted to but 21 while at the University of Glasgow the number was 131, it will surely be admitted that this is the reverse condition of what ought to obtain.

Correspondence.

THE THERAPEUTICS OF RHEUMATIC ENDOCARDITIS (THE LETTSOMIAN LECTURES).

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I find it necessary to make a few observations with reference to Dr. J. J. MacLagan's communication in your last issue.

With regard to the treatment of the various manifestations of the rheumatic process by salicin or the salicylates I am in accord with Dr. MacLagan. I have examined and tested the extant evidence, and have concluded that the pain and pyrexia of rheumatism are reduced by such treatment in so marked a manner that I would always employ it in any manifestation of acute rheumatism. The preference which Dr. MacLagan gives to salicin over the salicylates will induce me to give it careful trial—it is quite probable that salicin, a bitter tonic, may dispose to a more speedy convalescence than salicylate of soda, a possibly depressing saline. It must not be forgotten, however, that Dr. Isambard Owen has advanced important evidence derived from the experience of St. George's Hospital to the effect that the best results were obtained when the salicylates were administered in combination with alkalies—the latter in doses sufficient to render the urine alkaline. It is quite probable, nevertheless, that salicin, in combination with alkalies, may give better results than the salicylates in such combination.

Again, I am quite in accord with Dr. MacLagan when he advises the early administration of the drug in any rheumatic manifestation—that is, immediately upon the case coming under observation. Whether the dose recommended by Dr. MacLagan—20, 30, or even 40 grains every hour for six hours or until pain is relieved—errs on the side of excess can only be proved by experience as to toxic effects. The advice *frappez fort et frappez vite* is sound provided the blow be not too heavy. Dr. Isambard Owen, however, says that the advantage was least marked when the salicylate was given in large initial doses without alkali, and more marked for the salicylate in moderate initial doses. I quite think that the salicin treatment should be put in force as early as possible, and that the doses should be sufficient,

for there is a *prima facie* probability, as I have said, that the agent which reduces the pyrexia of rheumatism shall also reduce the inflammatory process which is its concomitant wherever that process may be manifested. Dr. MacLagan says, "it is by no means certain that we may not, in some cases, by the early and free administration of the salicyl compounds, prevent the inflammation and consequent thickening of the valve" in rheumatic endocarditis. "If we see a case early, and give these compounds freely, we may prevent the heart from suffering, as we undoubtedly do prevent joints from suffering." This is both possible and probable. My object in my Lettsomian Lectures was to enunciate the lessons told by hard facts. These were, I considered to the effect that the salicin compounds as at present employed, valuable as they were in reducing the sum total of fever and of suffering, had in no appreciable degree lessened the liability to heart complications. It may well be, however, that with an extended experience, a more prompt and more efficient application of the remedies, a more encouraging lesson may be taught by future statistics, and that rheumatic endocarditis may be possible of prevention if only we are enabled to observe the case sufficiently early—but there's the rub.

On the question of the pathology of rheumatic endocarditis, I am afraid that I am considerably at variance with Dr. MacLagan.

Dr. MacLagan says of the endocardium, "when it is affected in acute rheumatism there is no general inflammation of its surface, such as is found in the pericardium and synovial membranes. The mischief is limited to a small portion of one surface of the affected valve." This view, although very generally accepted, is by no means in accord with my observations. One of the chief purposes of my first Lettsomian Lecture was to show, by a reasoning that was necessarily condensed, that the endocarditis of acute rheumatism is much more widely spread than appears by a naked-eye inspection. The bead-like elevations on the surface or borders of the valves, or on the endocardium, are but the concomitants of an extensively-diffused inflammation. The whole tissue of the valve is swollen; it is seen under the microscope to have lost its normal fibrous appearance, and to be infiltrated with cellular elements; these are scattered throughout the whole thickness of the valve, though they are sometimes aggregated at the free surfaces or borders where friction may intensify the inflammatory change. The inflammation, moreover, is not confined to the endocardium; the exudation spreads to, and infiltrates the muscular structures to which the valves and the tendinous cords are attached, and even the root of the aorta, as preparations made by my colleague, Dr. F. Charlewood Turner, demonstrate.

I cannot, therefore, accept the friction theory as accounting for rheumatic endocarditis, though friction may well be a cause determining the aggregation of cellular elements at certain spots of the endocardium, the formation of beads and the deposit on the devitalised surfaces of the little caps of fibrin with which we are familiar.

The evidence seems to me to point strongly to the conclusions that the endocardium is attacked in rheumatism at a very early period of the disease, that the advent of endocarditis may be extremely insidious, and that, though we may hope much from the very early administration of the salicyl compounds, the probabilities of successful treatment reside chiefly in the employment of preventive measures.

I am, Sir, yours faithfully,

A. ERNEST SANSOM.

84 Harley Street, W., Feb. 24th, 1883.

SALICIN IN RHEUMATIC FEVER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I think that Dr. MacLagan's views as to the method of successfully exhibiting salicin in rheumatic fever are more recognised than he appears to imagine. It is perfectly useless to administer it in doses of 15 or 20 grains every three hours.

This morning a severe case of rheumatic fever, with a temperature of 101.4°, came into St. Vincent's Hospital; and my instruction was to give 30 grains of salicin every hour for six hours. I ordered that if the temperature did not reduce after the third dose, the quantity should be increased to 40 grains. As soon as the temperature should be decidedly lowered, I ordered the dose (whichever it might be) to be continued every second hour until the pain should

be gone, and the normal heat restored. If I may speak from the analogy of many former cases, I expect to find this condition of things to-morrow morning. Again and again I have verified the truth of Dr. MacLagan's assertion that "the course of acute rheumatism may be arrested within twenty-four hours of the time that treatment commences." To ensure this most desirable result, however, it is indispensable to give the salicin boldly and freely. I have always found 40-grain doses to answer; but, if they did not reduce the temperature, I would give more. There is not the slightest danger; and the clinical thermometer will prove an unerring guide.

I have long since discontinued the use of sodium salicylate. It is inferior to the salicin; and patients treated by the latter, as Dr. MacLagan observes, convalesce more rapidly. Still more important, while there is practically no limit to the doses of salicin, the sodium compound often disagrees, and has to be discontinued.

With such rapid treatment there is hardly time for cardiac complications; still I cannot agree with Dr. MacLagan that "a joint generally recovers from rheumatic inflammation, and that the heart does not." I believe that if from the outset the patient's heart be examined daily, whether he complain of it or not, inflammation will be found out in time; and that blistering and rapid but slight mercurialisation (going on with the salicin all the while) will arrest the mischief. On account of the recumbent position the heart affection seldom causes inconvenience; and the patient's attention is taken up with his inflamed joints. For these reasons the cardiac mischief is often overlooked altogether, or until irreparable mischief has been done.

When the pain is gone and the temperature become normal, the salicin may be given every third hour, then every fourth, and subsequently three times a day. It should be continued morning and night for a fortnight unto convalescence, and once a day for another fortnight; otherwise a relapse may occur. I believe it will yet be proved that rheumatic fever is a bacillar disease.

If the pain be severe, I am in the habit of using hypodermic morphia to tide the patient over the painful first six or eight hours. Also, generally a chloral and potassium bromide draught for the first night or so. These measures much conduce to the comfort of the patient, and do not interfere with the salicin.

Where quinine and other really expensive drugs are used in such quantities, even in hospital practice, the price of salicin cannot be a consideration. It is, however, inexpensive. In this city the cost is from tenpence to a shilling per ounce. The raw material can be obtained in any quantity in spring; and the extraction process is simple. In large doses it is best administered in wafer paper, or in capsules. Stirred up in a little cup of milk it is taken very easily. A drop of solution of salicin placed under the microscope, with the polarising apparatus appended, exhibits one of the most beautiful kaleidoscopic displays that can be imagined.

I am, Sir, yours, &c.,

F. J. B. QUINLAN, M.D., F.C.P.,
Professor of Materia Medica and
Therapeutics, Catholic University;
and Examiner in the same, Royal
University.

29 Lower Fitzwilliam Street, Dublin,
23rd February, 1883.

P.S.—25th February, 1883.—The date of your publication enables me to add a brief note upon the progress of this patient—a strong-looking woman, aged 42, and who had been ill for four days previous to admission. The joints affected were both knees, along with the left hand and wrist, which were hot, swollen, painful, and immovable. The tongue was white, the skin dry, pulse 120, and temperature 101.4°. The salicin was commenced at 11 a.m. on Friday, the 23rd, in 30-grain doses, and continued every hour up to 5 p.m. At 5.30 p.m. (after seven doses) the temperature was down to 100°, and the pain was nearly gone. The salicin to be given every second hour. The patient slept a good deal during the night, and this could not be done with exact regularity; the quantity, however, was given.

Saturday, 24th.—Much better; pain gone; temperature 99.2°. Continue the salicin every second hour.

Sunday, 25th, 11 a.m.—All fever gone; temperature normal; tongue clean; joints still swollen, but cool, painless, and movable. I expect a quick and good convalescence.

THE BUMBLEDOM OF THE ROYAL COLLEGE OF PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR—The bumbledom of the Royal College of Physicians richly deserves the withering sarcasm which you bestow upon it in your last week's issue. There is a mock sincerity in all their doings with regard to the vexed question of advertising. The cynicism of our would-be censors is made more apparent than ever just now when, with an utter disregard of decency, they flaunt a most offensive advertisement in the face of our families in the most conspicuous part of the *Times* newspaper, and which would be considered very disgraceful if it emanated from the quack you have lately exposed. It runs thus:—"The Gulstonian Lecture, *On the Sterility of Women*, will be delivered at the Royal College of Physicians by J. Matthews Duncan, M.D., F.R.C.P., &c." Can anything be in worse taste than this in the way of advertising one of their prominent Fellows?

I remain, yours, &c.,

A MEMBER OF THE COLLEGE.

February 26^h, 1883.

Medico-Legal Intelligence.

BREACH OF CONTRACT FOR MEDICAL COACHING.

THIRSK COUNTY COURT, FEBRUARY 21, 1883.

(Before E. R. TURNER, Esq., Judge.)

THIS was a case in which George Moore, M.D., L.R.C.P., of London, summoned J. J. Eberle, L.R.C.S., L.R.C.P. Edin., for £40 for a breach of contract said to have been entered into with him for the coaching of his son as a preparation for the medical profession.

The plaintiff was represented by Mr. Skidmore, of Darlington (instructed by Mr. A. W. Cass, of Thirsk), and the defendant by Mr. Mellor, of Leeds (instructed by Mr. Dale, of York).

It appears that the plaintiff, Dr. George Moore, had sent his son, George Lennox Moore, to Dr. Eberle's establishment in Thirsk to be prepared for the medical profession in the spring of 1882, and had paid for his coaching up to the end of October. In the meantime some misunderstanding arising as to the fulfilment of the contract, the plaintiff instituted the present action. After counsel for the plaintiff had waded through a considerable amount of correspondence relating to the absence of any systematic course of teaching on the part of the defendant, his Honour came to the conclusion that unless one of the letters put in was stamped he could not go on with the case. The contending parties then left the Court to see if an amicable arrangement could not be come to. On returning into Court, Mr. Skidmore, for the plaintiff, announced that an arrangement had been made, the defendant agreeing to pay £13 6s. 8d., and to withdraw any imputations which had been made. The case was then withdrawn, his Honour remarking that, had the defendant acted honestly at the beginning of the matter, there would have been no occasion for the present action.

Royal Colleges of Physicians and Surgeons, Edinburgh.—

Double Qualification.—The following candidates having passed the necessary examinations, were admitted L.R.C.P. Edin. and L.R.C.S. Edin.

- | | |
|------------------------------------|-------------------------------------|
| Adams, A. M., co. Londonderry. | Gormley, J. Jhu, co. Roscommon. |
| Albrecht, John Adolph, Pendlecon. | Green, J. Unsworth, Worcestershire. |
| Ambler, James, Lisburn. | Irwin, W. S. muel, Dublin. |
| Campbell, Kenneth J., Yorkshire. | Kemin, F. St John, Wiltshire. |
| Clark, George, Belfast. | Macd naid, W. Hector, Toronto. |
| Clarkson, H. G. H., Yorkshire. | MacKenzie, Murdoch, Stranaway. |
| Clay, Charles, Wiltshire. | Mosent, Walter, Nackington. |
| Conamoney, Austin, co. Galway. | Nichol, Edward H. Bird, Milton. |
| Curia, James Henry, Cork. | Owen, Rowland, Holywell. |
| Curie, Robert, B. Lyvena. | Paul, David Robert, Vizagpatam. |
| Dunlop, Joseph, Conagher. | Rogers, S. Robert, Ontario. |
| Fernandes, Ambrosio F., Goa. | Smyth, James, co. Limerick. |
| Foulis, Robert James, Edinburgh. | Steeple, Adam R., Australia. |
| Fleet, William Simpson, Cullinst. | Tranwood, William, Rathfriland. |
| Fletcher, W. J. H., Staffordshire. | Van Rooyen, G. St. Clair, Columbo. |
| Givin, Robert Daniel, Derroek. | Weichman, Eliot W., Lichfield. |

Royal College of Surgeons, Edinburgh.—

The following candidates were admitted Licentiates of the College on January 26th—

1. Dick Lucia Nicholls, Esq.; Thomas O'Kelly, County Clare,

During January the following also passed their final examination for the Dental Diploma, and were admitted L.D.S.:—
Frank Herbert Briggs, Leeds; Francis Bromley, London.

Faculty of Physicians and Surgeons of Glasgow.—The following candidates, having passed the necessary examinations, were admitted Licentiates at the January sittings:—

- | | |
|--------------------------------|-------------------------------------|
| Binnie, Robert M. G., Glasgow. | Si clair, Hugh, Glasgow. |
| Church, William, Glasgow. | Steele, Andrew Neil, Glasgow. |
| Churchouse, Wm. J. F., Chard. | Tovey, Richard A., Glasgow. |
| Gibson, James, Doune. | Whitecombe, Ch., Christchurch. |
| Prowde, E. L., M.B., Mel-onby. | Woolfsen, Louis E. G. de, S. Devon. |

King and Queen's College of Physicians in Ireland.—At the usual monthly examinations for the Licences of the College, held on Monday, Tuesday, Wednesday, and Thursday, February 5, 6, 7, and 8, the following candidates obtained the Licence to practise Medicine:—

- | | |
|-------------------------------------|---|
| Beattie, W. T., Doovary, Omagh. | McClighry, T. P., Riverstown, co. Wick. |
| Coke, Thomas Joseph, Hull. | Shro. |
| D. Iv, Ch. A., Charville, co. Cork. | Mackintosh, G. D., Harrogate. |
| Lane, Thomas, Rathmine, Dublin. | S rickland, C. E., Kildgreve, Staffs. |

The following obtained the Licence to practise Midwifery:—

- | | |
|--|--|
| Croke, Thomas Joseph. | Henry, James, M.D., Monaghan. |
| Daly, Charles Andrew. | lane, Thomas. |
| Henderson, F. D., M.D., Kils, co. Derry. | Morell, L. D., M.D., Ballysby, co. Moaaghan. |

The following Licentiates were admitted Members:—

- | | |
|----------------------------|-------------------------------|
| Falkiner, Thomas Falkiner. | Flanagan, John Wm. H., A.M.D. |
| Vesey, Thomas A. G. B. | |

Edinburgh University.—The following bursaries, &c., were awarded at the competitive examinations in the Faculty of Medicine during the session 1881-1882. First Year Bursaries: Subjects of preliminary examination required for first professional examination. The Thomson Bursary of £25 a year to Mr. Arthur Clarkson. The Grierson Bursary of £20 to Mr. James Taylor. The Thomson Scholarship, in Botany, Zoology, and Elementary Mechanics, of £40 a year, to Mr. Alexander Edington. Third Year Bursary: The Grierson Bursary, in Anatomy and Physiology, of £20, to Mr. Paul Bowes. Fourth Year Bursary: The Tyndal-Bruce Bursary, in Materia Medica and Pathology, of £25, to Mr. Thomas E. Dyson. The Neil-Arnott Prize, in Experimental Physics, of £40, was awarded to Mr. John Morrison.

The Cancer Hospital, Brompton.—At the annual general meeting of the Governors of this Hospital on the 21st inst., Earl Sydney, President, in the chair, the 32nd annual report of the committee showed that there had been a falling off of income from legacies and donations, and a slight increase in annual subscriptions. The extension of the building is progressing satisfactorily, and a large portion has been already occupied by patients, and it is hoped that the whole of the extensive works will be finished in the early summer, and the usefulness of the charity thus increased. The medical report showed that 994 new patients were received during the year, 275 being in- and 719 out-patients. Of the in-patients, 92 were treated by operation, and 183 by other means. The customary votes closed the proceedings.

The Sanitary Assurance Association.—The second annual meeting of the Sanitary Assurance Association was held on Thursday last, Professor T. Hayter Lewis, F.R.I.B.A., in the chair. The secretary read the report of the council for the year 1882, from which it appeared that the inspection of houses, supervision of work, and issue of certificates had been continued on the plan initiated by the Association in 1881. The property placed on the Assurance Register and inspected during the year had varied in annual rateable value from £10 to £1,000, and in every case the sanitary arrangements had been found to be defective. Professor Hayter Lewis, in moving the adoption of the report, referred to the work done by the Association during the past year, pointed out that the officers of the Association had inspected a much greater number of houses than in the preceding year; still, he was of opinion that, when the benefits to be derived from such operations were considered, the progress ought, for the future, to be still more rapid. Great good had, however, been done, and he believed that there was ample promise of further good in the same direction. The report having been adopted, Mr. Mark H. Judge proposed, and Professor Roger Smyth, F.R.I.B.A., seconded, the re-election of Sir Joseph Fayer, F.R.S., and Mr. H. Rutherford, as members of the council.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

DR. RAYNOR.—A committee has been appointed to investigate the subject, and will be glad, doubtless, to receive any information you may be able to provide. The results hitherto obtained have not all been successful, even in the hands of those who have recorded the least amount of failure.

MR. JEPSON asks to be informed whether any one has ever been known to walk immediately after receiving such injuries as produced fracture of both bones of the leg? We do not know of any such instance; but the possibility of locomotion with an impacted fracture of the tibia in which one end is driven into the other and firmly looped, is quite conceivable. Our correspondent does not say he has seen such a case as he mentions. Perhaps some reader of the *Medical Press* can reply to his question.

PERTUSSIS (No. 1).—As the ticket was issued by the R.O., the case is not a very favourable one to sue for your fee; but you would recover the amount if you could show that the ticket had been obtained by a false representation.

PERTUSSIS (No. 9).—In the book referred to on "Whooping-Cough and its Treatment," you will find an appendix of formulae giving the prescriptions of about fifty of the leading English and foreign authorities. The particular ones referred to in your note are as follows:—

5.—Potas. bicarb., gr. xv.;
Cocci caeli, gr. viij.;
Aque destil., f. ℥vj.

Rub together, strain, and add acid. hydrocyanic dil. ℥x. A teaspoonful when the cough is troublesome.—Dr. Granville.

6.—Cocci pulv., 1 scruple;
Potas. carb., ℥j.;
Aque ferventis, ℥viij.

Rub together and strain. A teaspoonful thrice daily.—Dr. Allnatt.

DR. IRVING (Liverpool).—We will again look into the matter and see if any other points can be brought out.

MR. BAKER (Portsmouth).—The case is one commonly seen amongst lunatics, and has been reported on in various media.

INVALID TRANSIT AT THE WESTMINSTER HOSPITAL.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—As I have endeavoured since 1874 to impress on our profession the advantages of alighting patients during locomotion, may I ask you to kindly publish the following facts:—

On February 24th, 1883, I wanted to send a young lad into the country on whom amputation of the right hip joint had been performed, and who was slowly but surely losing ground by reason of the discharge arising from pelvic necrosis. The neighbourhood of the acetabulum was encircled by sinuses, and the lad was intolerant of local interference, and of any pressure on his right side or buttock. His home was at Harlington, Middlesex (15 miles from town); so I ordered one strong horse and drove my invalid van to the Westminster Hospital. The lad was placed in one of my stretchers on a hair mattress at his bedside, carried down to the van, and slung to its roof by two elastic cord suspenders. The journey occupied 2½ hours, and he was carried into his own home, not only delighted by the drive, but also unhurt by one single jolt or concussion. I personally sat by his swag-bed during the whole journey, and gave him sandwiches and port at half-way distance; on the return journey I laid in the stretcher and dozed off luxuriously. I may also remind charitable benefactors that ambulance work was not unknown to the Good Samaritan, for in addition to other kindly services rendered to the wounded man, *he set him on his own beast and brought him to an inn*—(παροχέϊον) (δέχομαι, I receive; was, everyone)—a singularly expressive word for a hospital.

I am, Sir, your obedient servant,

RICHARD DAVY.

Surgeon to the Westminster Hospital.

DR. DAVIS.—The subject is at present under consideration; with the data at our disposal, we doubt if the profession is ripe for such radical measures. We doubt also the wisdom of many of the premises.

AN AFFECTION FOR LUNATIC ASYLUMS.—A somewhat strange case came before the Chester magistrates last week. It was that of a man, Henry Wickham by name, who was charged with being a wandering lunatic. When in the cells the prisoner was induced, only after much persuasion, to dress himself, as he declared it interfered with his breathing. In the dock the prisoner delivered an oration about George Washington and Columbus. He also confidentially informed the magistrate that he had married the handsomest woman in Philadelphia. He was then sent to the County Lunatic Asylum. Up to this point Wickham had acted his part very cleverly. At the Asylum, however, the officials recognised him as having been in that institution four times before. Mr. Fenwick, the chief constable, Chester, then instituted inquiries, and discovered that the prisoner had sojourned for short periods in over forty county lunatic asylums, Wickham being, it is supposed too lazy to work, simulates madness in order to obtain better fare and treatment at lunatic asylums than is to be obtained either in county prisons or casual wards.

DR. H. A. H.—Will make inquiries with a view to enlisting the necessary influence.

MEETINGS OF THE SOCIETIES.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—To-day (Wednesday), at 4 p.m., Professor Flower, On the Anatomy of the Horse and its Allies.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—To-day, at 5 p.m., Croonian Lecture: Dr. J. E. Pollock, On Modern Theories and Treatment of Phthisis.

HUNTERIAN SOCIETY.—This evening, at 8 p.m., Address by the President (W. Rivington, F.R.C.S., M.S.).—Dr. Fye-Smith, On Mistakes in Diagnosis, illustrated by cases.

ROYAL INSTITUTION.—Thursday, March 1st, at 3 p.m., Professor Dewar, On the Spectroscope and its Applications.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Thursday, March 1st, at 8 p.m., Annual Meeting: Report, President's Address, &c.

HARVEIAN SOCIETY.—Thursday, March 1st, at 8.30 p.m., Mr. Edmund Owen, On the Simple Treatment of Congenital Talipes.—Mr. Percy Boulton, On the Treatment of Post-partum Hemorrhage.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Friday, March 2nd, at 4 p.m., Professor Flower, On the Anatomy of the Horse and its Allies.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Friday, March 2nd, at 5 p.m., Croonian Lecture: Dr. J. E. Pollock, On Modern Theories and Treatment of Phthisis.

ROYAL INSTITUTION.—Friday, March 2nd, at 8 p.m., Mr. C. V. Boys, On Meters for Power and Electricity.

ACADEMY OF MEDICINE IN IRELAND.—Pathological Section, Friday, March 2nd, at 8.30 p.m.—Living Specimens: Mr. Croly—1. A Young Man from whose Foot the Astragalus was Removed; 2. A Case of Mr. Syme's Amputation of Foot.—Specimens exhibited by Card: Mr. Croly—1. (e) Bones removed in Excision of Elbow; (b) Wrist; (c) Knee; (d) Shoulder; 2. Sarcomatous Tumour of Leg; 3. Scirrhus Tumour of Breast; 4. Jacob's Ulcer; 5. Epithelial Ulcer; 6. Fatty Tumour; 7. Urinary Calculi; 8. Preputial Tumour; 9. Sarcomatous Tumour removed from Antrum.—Dr. Quinlan—1. Bacillus Anthracis in Blood; 2. Bacillus Anthracis in Lung Tissue.—Dr. Tweedy, Hydrocephalic Brain.—Dr. Warren, Recurrent Fibro-Myxoma.—Mr. Abraham, Dislocation and Hypertrophy of Roof of Horse.—Dr. McDonnell, Scirrhus from the Male Breast (set. 29), with Microscopic Mountings.—Dr. Duffey, Carcinoma of Liver, with Microscopic Sections.—Papers: Dr. Abraham, Notes on Blood-vessels of New Growths.—Dr. R. H. Bennett, Congenital Defect of the Rectum.—Dr. F. W. Warren, Obstruction of the Inferior Vena Cava.

ROYAL INSTITUTION.—Saturday, March 3rd, at 3 p.m., Dr. W. H. Stone, On Singing, Speaking, and Stammering.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—Monday, March 5th, at 8 p.m., Casual Communication by Mr. Ackery.—Adjourned discussion on the following question, propounded by Mr. Sewill: Do the incontrovertible facts which we now possess as to its Etiology and Pathology fully account for the phenomena of Dental Caries?—Paper by Dr. John C. Thorngood, On Therapeutic Agents for the Promotion of Osseous Development.

Vacancies.

- Dunfanaghy Union, Crossroads Dispensary.—Medical Officer. Salary, £110. Election, March 7th.
- Great Northern Hospital, Caledonian Road, London, N.—Junior Resident Medical Officer. Board and lodging are provided within the hospital, but no salary. Applications to be sent to the Secretary not later than March 10th.
- Hospital for Consumption and Diseases of the Chest.—Resident Clinical Assistant. Applications to be forwarded not later than March 2nd.
- Royal Hospital for Diseases of the Chest.—House Physician. Salary at the rate of £80 per annum is made in lieu of board. The post is tenable for six months. Applications to be forwarded to the Secretary by March 8th.
- University College, London.—Dental Surgeon and Lecturer on Dental Surgery. Applications to the Secretary before Feb. 23th. (See Advt.)
- Walsingham Union.—Medical Officer. Salary, £68 10s., exclusive of the authorised fees for surgical, vaccination, and midwifery cases. Applications to the Clerk on or before March 6th.

Appointments.

- BENNETT, S., F.R.C.S. (Exam.), L.R.C.P.Lond., L.D.S., Dental Surgeon to the Middlesex Hospital.
- HEATH, C., F.R.C.S. Eng., Consulting Surgeon to the North-West London Hospital.
- HUMPHREYS, E., M.R.C.S., Medical Officer for the Llanfairtalhaiarn District of St. Asaph Union.
- JAMES, W. C., M.D., C.M., F.R.C.S.E., Physician to the Hospital for Women and Children, Vincent Square, S.W.
- MADDISON, W. T., M.B. Lond., M.R.C.S., House-Surgeon to the Royal Surrey County Hospital, Guildford.
- PIE, W., F.R.C.S., Surgeon to the Victoria Hospital for Sick Children.
- SMALE, M., M.R.C.S., L.D.S., Dental Surgeon to the Westminster Hospital.

Deaths.

- BACON.—Feb. 22nd, at the County Asylum, Fulbourn, Cambs., G. M. Bacon, M.D., M.A., Medical Superintendent of the Asylum, aged 47.
- BALL.—Feb. 14th, at Spalding, Lincolnshire, Ancell Ball, L.R.C.P.M., J.P., aged 66.
- COMBER.—Feb. 14th, at York Place, Edinburgh, James Scarth Comber, M.D., aged 87.
- ROBINSON.—Feb. 10th, at Forest Gate, Essex, Henry William Robinson, late of Her Majesty's Indian Army, aged 63.

The Galstonian Lectures

ON

STERILITY IN WOMAN.

Delivered in the Royal College of Physicians, London, February, 1883.

By J. MATTHEWS DUNCAN, M.D., F.R.C.P.L., Physician-Accoucheur and Lecturer on Midwifery at St. Bartholomew's Hospital, &c.

LECTURE I.—PART II.

ITS NATURE AND AMOUNT.

THE second question proposed is, How rapidly do the children in a family follow one another? or, What is the interval between the births of successive children? Great authors on population used to hold that breeding women never exceeded, in rate of prolificness, a child every two years; but, like many of the other principles on which Malthus and the rest based their theories, this has proved to be false. With our present knowledge, we can assert that Malthus erroneously endowed womankind with a degree of relative sterility, for women who breed do so at an average rate of a child every eighteen months, or nearly so.

I here give a table compiled from the Edinburgh and Glasgow registers, which makes the average interval between successive children nearly twenty months. But this requires several corrections, which will, on the whole, tend greatly to reduce the amount. Twins are included, and counted as two children. But a source of greater error is the exclusion of dead children, whether one or more. This last error might not be grave, or even an error at all, in the view of an economist such as Malthus; but reckoning for it would make his actual error comparatively much greater.

TABLE IV.

Showing the Average Duration of Marriage at Birth of each Successive Child, and the average Interval between the Births of the Successive Children.

Number of children.	Number of mothers.	Duration of marriage in months.	Average interval between successive births.
1	3722	17	—
2	2893	38	19·0
3	2534	64	21·3
4	1982	90	22·5
5	1543	115	23·0
6	1221	137	22·8
7	848	162	23·1
8	641	181	22·6
9	425	203	22·5
10	222	225	22·5
11	152	235	21·4
12	61	246	20·5
13	34	263	20·2
14	11	281	20·1
15	6	280	18·7
16	2	336	21·0
17	2	252	14·8
18	1	252	14·0
19	1	204	10·7
Average			19·9

Table IV., like Table V., made up from Ansell, is not correctly described as giving the average interval between births, but as giving the average interval between the marriage and the birth of the child, divided by the number of children born, which is a near approximation to what is wanted.

TABLE V. (from Ansell.)

Showing the Mean Time after Marriage of Successive Births, and the Average Interval between them.

Order of birth.	Mean time of birth after marriage.	Average interval between successive births.
1st child	1.32 years	—
2nd "	3.02 "	18.0 months
3rd "	4.83 "	19.0 "
4th "	6.69 "	20.0 "
5th "	8.53 "	20.0 "
6th "	10.28 "	20.5 "
7th "	11.92 "	21.0 "
8th "	13.47 "	20.0 "
9th "	14.93 "	20.0 "
10th "	16.33 "	20.0 "
11th "	17.65 "	19.0 "
12th "	18.85 "	19.0 "
13th "	19.87 "	18.0 "
14th "	20.71 "	18.0 "
15th "	21.41 "	17.0 "
16th "	22.01 "	16.5 "
17th "	22.54 "	16.0 "
18th "	23.02 "	15.0 "

Ansell's table does not require correction for twins or for dead-born children, and its value may be judged by the statement, indefinite though it is, that it is based on more than 25,000 observations. The average interval, as calculated from them, is eighteen months. Ansell's table may be studied, further, with a view to a statement of the average interval in those who have not excessive families, but families of natural or normal number. For those mothers who have shown excessive intensity of fertility, either by a high number of births or by excessive rapidity so long as childbearing continued, are mixed up in each successive row of figures with those that are normal, or nearly so. Now, looking at the rows of figures of families varying from four to ten, which show intervals of twenty to twenty-one months, we are safe in stating the average interval for normal families as above twenty months, yet, probably, considerably under two years.

It may therefore be held that a married woman who, during childbearing life, does not have a child every twenty months is exhibiting relative sterility.

The third question is, When did childbearing cease? or, What was the age at the birth of the last child? Now, it is the rule to confuse the childbearing period of life with the period during which a woman menstruates, and this is a great mistake. It is only a part of this that, in married life, is occupied by childbearing, except in rarest cases, such as have never come under my observation. When a woman begins childbearing she generally, under favourable circumstances, continues her career of fertility steadily till her last child is born.

The registers tell us when women actually begin to have children, and I have already made use of such information, but we have no data nearly sufficient to decide what is the average age of commencing fertility; we may, however, be sure, from what we do know, that it is not the age of puberty or of commencing menstruation, and that it is not the age of nubility or age at which procreation is commenced with the greatest advantage to mother and progeny. It is evidence of good conduct in the race that we cannot get sufficient data, there being very few unions permitted in early life. The great mass of our women are, fortunately, married within the limits of nubility, or the marriageable age. Nevertheless, it is very desirable that we should find out what is the mean age of commencing childbearing.

Regarding the time of cessation of childbearing we

have more exact information, and it shows well the distinction that must be made between the cessation of menstruation and the cessation of procreation. Menstruation ceases at from forty-five to fifty years of age, but childbearing ceases at an average age of thirty-eight. This cessation arises from no imperfection or decay of organs, that has been demonstrated, but it may be due to that nevertheless. It is highly probable that its main cause is a cessation of functional vigour or activity, for it is delayed in women who have begun their fertility late in life.

On the subject of the cessation of childbearing our best information is derived from Ansell, whose calculations are based on 4,899 observations, restricted to those in which both the father and mother survived the childbearing age of the latter, a point which was determined as regards each case in accordance with a scale already given, whose chief governing rule is not to suppose a woman under forty-four years of age to have borne her last child until she has been for ten years barren. The quinquennial 39.43 is that at which the largest number ceased to bear children. Thirty-eight years is the mean age of mothers, married at the mean age of twenty five, at the date of the birth of their last children in cases where childbearing was not prematurely terminated by the death of either parent.

The productive period begins earlier, and it is protracted to a later age, in cases where the children are numerous than where they are few. This protraction is shown by the following table:—

TABLE VI. (from Ansell.)

Showing the Mean Age of Mothers at the Birth of their last Child in Families of different numbers.

Number in family.	Mean age of mother.
1	31.08
2 or 3	34.21
4 or 5	37.04
6 or 7	39.21
8 or 9	40.61
10, 11, or 12	41.74
13, 14, or 15	42.83
16 or more	44.32

Women have, in their career, and with a view to our present subject, many stages in life. There is the age of puberty or of commencing menstruation, and this is to be distinguished from the age of commencing childbearing, regarding which we have no data adequate for a decision. But the age of commencing childbearing, though it may be identical with that of commencing menstruation in individual cases, is certainly not nearly so in the mass of women, being fortunately considerably delayed. Then, after the age of commencing childbearing comes the age of nubility or marriageable age, that at which a woman can enter on married life with the best chances of having a healthy and not excessive family. After the age of nubility comes the age of cessation of childbearing, which, as already said, is thirty-eight for women married at twenty-five years of age. A woman may bear children after this age, or even after the cessation of menstruation, but such cases are exceptional and rare. The last stage in their career is generally the cessation of menstruation at an age of forty-five to fifty.

There is a mean age of puberty and of commencement of possible procreation, a still farther advanced mean of commencing procreation, a still farther advanced mean of nubility or fitness for procreation, a still farther advanced mean of cessation of procreation, and lastly comes the mean of cessation of menstruation and of possible procreation. Most of these stages of woman's life have their analogues in the female life of the lower animals which are best known to us, and some of them have analogues in the life-history of plants. There can be no doubt that they all have their coordinate physical states of the genital organs, and in this

department there has been much successful anatomical investigation, especially as regards puberty, nubility, and the cessation of menstruation.

Writing regarding the age of cessation of childbearing, Whitehead makes the following pertinent remarks:—"The sum of the ages of the individuals (38) recorded in the preceding table, at the time of their last delivery is 1586, giving an average of 41.73 years; the average age of the same individuals, at the time of their last menstruation, is 47.54 years; so that a period of nearly six years is here indicated, during which, although the menstrual function continued to be more or less efficiently discharged, and the health good, aptitude for procreation did not exist. They were all placed under equally favourable circumstances for the continuance of childbearing so far as regarded their matrimonial position. . . . A like period of uterine quiescence," he adds, "is observed before childbearing begins."

The average cessation of childbearing is for all women no doubt between thirty-five and forty years of age, and a woman in whom this career ceases earlier shows relative sterility.

To the question, how long does childbearing continue? it is easy to give some answer; for if the average age at the commencement of childbearing is twenty-six years, and the mean age at termination is thirty-eight, the average duration of childbearing is twelve years. The duration of fertility will be the number of pregnancies multiplied by nine (months) added to the number of intervals multiplied by nine (months). It will vary therefore from a case of one-child sterility, with nine months of the childbearing period of life, to a case of ten-child fertility, with a childbearing period of life of 171 months, or about fourteen years; and to a case of twenty child fertility, with very much less than thirty years of childbearing life; very much less, because women of this great and excessive prolificness do hurry their children into the world to get through the high number.

From Ansell's table of 4899 married women, whose ages at the birth of their last children were known, and where both parents survived the childbearing age of the mother, I have constructed the following table to show the nearest figures I can give to the actual lengths of childbearing life in families of different members. The commencement of childbearing at twenty-six years of age is, in all cases, assumed, because it really was very nearly the mean age in Ansell's collection:

This table affords us further valuable information as to the duration of childbearing in families which reach the normal limit of about ten, and we see that it is about fifteen years. A woman then may be regarded as relatively sterile who, married within the years of nubility (about 20-25), ceases to have children within fifteen years from the birth of her first child.

We must now try to answer the last and comprehensive question, How many children does a woman bear? On the answer to this depends the settlement of the amount of relative sterility. It cannot be satisfactorily answered directly, on account of the paucity of data, but such answer as we can give is corroborated by the various subsidiary answers which we have just furnished. We shall not enter on subjects important politically, such as the numbers in actual families, the number to a marriage, &c., because these are foreign to our present inquiry.

In the district of St. George's-in-the-East the Statistical Society found, among the poorer classes, eighty mothers who had been married at ages varying from fifteen to nineteen, and who had lived in wedlock at least thirty-one years, or all the childbearing period of life. These fertile wives had borne on an average 9.12 children. Considering the undoubted existence of evident sources of error, all tending to unduly diminish the average amount of fertility, we may safely say, using the data of St. George's-in-the-East, that ten is about the

average fertility of fertile marriages lasting during the whole childbearing period of life.

The average age of marriage in England is twenty five, and consequently the production should be less than ten, the women living in fruitful wedlock from twenty-five till the end of the childbearing period of life, not all the childbearing period.

TABLE VII. (from Ansell).

Showing the Average Age at Cessation of Childbearing in Families of different numbers, and the time occupied in Childbearing, estimated at the rate of eighteen months for each child, in families of less than ten children: the mean age of mothers at commencement of childbearing being twenty-six years, and the parents both surviving the childbearing age of the mother according to the scale of Ansell (p. 50).

No. of family.	No. of cases.	Mean age of mothers.	Time occupied in childbearing.
1	244	30 years & 6 months	1 year & 6 months
2	401	32 " 11 "	3 years — "
3	425	34 " 5 "	4 " 6 "
4	485	35 " 10 "	6 " — "
5	535	36 " 11 "	7 " 6 "
6	494	38 " — "	9 " — "
7	490	39 " — "	10 " 6 "

The actual fertility of fertile marriages in England, if only nine in ten wives have living children, is, according to Farr, 5.2; but with a view to contrast with the data of St. George's-in-the-East and of Ansell this figure needs correction, for in making it up, the condition of living in wedlock till the end of the childbearing period of life is omitted. If that condition were not omitted, there would of course be a large increase of fertility of wives in England. Ansell's collection includes 1,767 spinsters married to bachelors at a mean age of twenty-five, and living in fruitful wedlock till the end of childbearing, as calculated by a scale already given, and the production was 5.7, or nearly 6, a figure which I regard as indicating a less fertility than that of Englishwomen generally.

The fertile wives of England, without the condition of persistency in married life till the end of the childbearing period of life, bore 5.2 children. Ansell's mothers in the upper classes, married at a mean age of twenty-five, and living in wedlock till the childbearing period of life was passed, bore on an average 6 children. The fertile wives of St. George's-in-the-East, a poor class, living in wedlock all the childbearing period of life, bore above 9 children. Each of these statements yields some corroboration of the others, and, keeping in view some further evidence, they seem to justify us in holding that a healthy woman, living in wedlock all her childbearing life, under the most favourable circumstances for natural procreation, should have a family of 10; or women, under such circumstances, bearing fewer than 10 are relatively sterile, and the sterility is inversely as the number.

Further evidence to the same effect is got by referring to the data derived from the registers of Edinburgh and Glasgow for 1855. There (Fecundity, p. 125, 2nd ed.) I found that in fertile wives married at various ages,

there was a fertility of between seven and eight, after a lapse of fifteen years of marriage, counting to the birth of the last child; and fifteen years is full allowance for persistence in fertility. Now, as many women are married some years after the best period for commencing childbearing, we may, by making allowance for such delay, raise the number from between seven and eight to ten.

There are many women who bear families above ten in number, and it is desirable to devote to them further special consideration. Such families are, on the whole, abnormal or excessive. For many an individual woman a family less than ten is excessive. We have, indeed, spoken of the occasional calamitous character of only-child fertility. But there is a mass of evidence tending to show that a family, in the average female, rising above ten, begins to be excessive, and increasingly so as the figure increases. It may seem paradoxical to bring the consideration of excessive families into a lecture on sterility, but in the next lecture the paradoxical character of this proceeding will disappear.

The bearing of a first child is well known to be very dangerous, often fatal, to the mother. After this she comes into a period of childbearing which is the safest, and which continues while she has a natural or ordinary degree of fertility. The danger of primiparity is, for a fertile woman inevitable, but the special danger of multiparity is incurred only when a family is excessive; and I hold this danger to be good evidence (along with other) of excessiveness. It is, at the same time, to be kept in mind that danger has been demonstrated to rise with increasing elderliness; but elderliness of the mother is an essential element in a question of excessive family. I extract from my work on Fecundity, &c., the following table, whose composition is there stated:—

TABLE VIII.

Showing a Comparative Percentage of Deaths in Successive Labours.

Number of pregnancy.	Number of mothers.	Number of deaths.	Percentage	Or 1 in
1	3722	254	6.82	15
2	2893	60	2.07	48
3	2534	64	2.52	39
4	1982	39	1.97	51
5	1543	31	2.01	49
6	1221	28	2.29	43
7	848	16	1.88	53
8	641	15	2.34	42
9	425	13	3.06	32
10	222	9	4.05	24
11	152	5	3.28	30
12	61	1	1.64	61
13	34	4	11.77	8
14	11	—	—	—
15	6	1	16.66	6

It does not give actual mortalities, but only such mortalities as may be compared with one another with a view to making out the peril attending confinements of different numbers.

In the sequel I shall give further and varied evidence as to the excessiveness of families above ten. This evidence is based not on the danger to the mothers only, but on the nature of the production—that is, on the occurrence of twins, of weakly children, and of idiots.

The chief veterinary surgeon of the Paris Prefecture of Police has issued a report for the past year upon the subject of hydrophobia, from which it appears that ten persons died from the effects of bites as compared with 23 in 1881.

AN ESSAY UPON HIP-JOINT DISEASE.

By S. D. CLIPPINGDALE, M.D., F.R.C.S.

(Continued from page 139.)

VI.—THE TREATMENT.

THE local treatment alone calls for discussion here. Any constitutional complication of the disease may require a constitutional remedy, but the constitutional treatment of the joint disease itself is identical with that which is required to keep the body of a healthy individual in a state of health, and consists in attendance to food, air, and hygienic requirements generally.

Any part of the body that is inflamed requires rest for its recovery. This is especially so in the case of an inflamed joint. If an inflamed part be not healed by rest, then, in order to save life and lessen suffering, its removal becomes advisable; this is what is necessary and practised in the case of an inflamed hip-joint.

The treatment, therefore, of a case of morbus coxae, consists, firstly, of rest, and if this be not effectual, then excision of the joint demands consideration.

In this section of the Essay, an endeavour will be made to ascertain, in the first place, the appropriate use and the best method of obtaining rest; and in the second place, the conditions which render necessary operative interference. Various opinions have been entertained by equally competent authorities as to the best method of obtaining rest; as to whether fixation alone of the joint is sufficient, or whether fixation should be combined with extension, and whether rest can and should be associated with movement of the joint. These views, and the methods of carrying them into practice can be conveniently described under three heads. These are, 1, simple rest; 2, rest with extension; and 3, rest with extension and motion.

1. *Simple rest to the joint* may be secured by enclosing the limb in a casing of such material as gutta-percha, leather, wire-gauze, starch, or plaster-of-Paris. It may also be obtained by the application of the long splint of Désault or Liston; or by the splint bearing the name of its inventor, Mr. Thomas, of Liverpool. This valuable splint is so commonly used that a description of it here seems unnecessary. A detailed account of it, however, such as to convey a thorough knowledge of its mechanism, and enable the practitioner to have one made "with no more mechanical aid than can be obtained from the village blacksmith and saddler," will be found in Mr. Thomas's work. (a)

With regard to the use of gutta-percha, plaster-of-Paris, &c., it may be stated that this method is effectual, but that the material is not always at hand, and requires experience in its application, and it is to be noticed that these appliances hide the affected part from view, a serious defect. The long splint is far more serviceable, and is in constant use in the hospitals of London. Its defect is, however, that it does not render the joint immovable in every position of the body; for, passing along the side of the body only, flexion of the limb can take place when the patient is turned over for nursing purposes. This objection does not apply to Thomas's splint, hence its peculiar value. Thomas's splint has been said to produce more wasting of the limb than any other. This is difficult to understand, for the wasting depends upon the amount of inaction, and not upon the form of splint used.

Of these various methods of securing rest, I would venture, therefore, to record my testimony in favour of Thomas's splint, although I duly acknowledge the great value of the long splint, but its failure to prevent flexion of the joint in all positions of the body, I consider a serious objection to its use.

To ensure the most perfect rest, the patient should be kept in bed, and not only kept in bed, but secured to it. It is advisable to confine the sound limb as well as the

(a) "Diseases of the Hip, Knee, and Ankle."

deflected one. This is done at some hospitals by the use of the "box-splint," or it may be effected by Thomas's double splint. It is of importance to attend to the structure of the bed, and other details of treatment. The success of a case often depends upon attention to these, apparently trivial, matters. The bed should be firm and flat, the head kept low, and the trunk immovable. Possibly, I cannot do better than describe the excellent plan carried out at the Alexandra Hospital for the treatment of Hip Disease in Children; there, the bed consists of a single plank, upon which lies a hard mattress; the pillow is small, just large enough for the head, about a foot square and flat. To secure the patient's body to the bed, an armlet is passed over each shoulder, the two armlets are fastened behind to a strap which passes across the back and is secured to the bed underneath. In front, the armlets are also connected by a band across the chest. This arrangement renders the patient immovable in bed, and doubtless contributes materially to the good results which seem to follow the treatment at the Alexandra Hospital.

2. Rest with extension.—According to Sayre, this principle was first recognised and carried into practice by Dr. Harris, of Philadelphia, in 1825. Dr. Harris seems to have used the long splint with extending and counter-extending bands. The mode in general use, and deservedly the favourite mode, is that by weight and pulley. In this method the trunk is fixed in some way so as to produce counter-extension, and extension is made by a weight attached to the limb. The weight and pulley seem to have been first employed by Sir Benjamin Brodie in St. George's Hospital. His account of it is to be found in the third edition of his work upon diseases of the joints.

In the application of the weight and pulley it is to be borne in mind that, by a law of mechanics, the weight is diminished by one-half by the passage of the cord over the pulley, so that if the weight be four pounds, the actual tension upon the leg is two pounds. Care should be taken to use no unnecessary amount of weight; only sufficient should be used to overcome the resistance of the muscles.

Instead of employing the weight and pulley, Mr. Barwell uses a splint designed by himself. Briefly, this apparatus may be described as consisting of a long splint with two pulleys, one at each end. The cords from these pulleys are connected together by an accumulator placed upon the outer side of the splint so that by this mechanism, extension and counter-extension are both manifestations of the same force.

3. Rest with extension and motion.—In this method of treatment the object aimed at is motion of the joint without friction of its surfaces. This plan originated and is principally carried out in the United States of America. The idea seems to have been conceived by Dr. Henry G. Davis, of New York, and first carried into effect by him in the year 1855. The apparatus he used is known as "Davis's splint," but there have been important modifications of it by Sayre, Taylor, Washbourn, and J. C. Hutchinson, all American surgeons. This method, which may with propriety be called the "American method," finds most favour in the country of its birth. Either from want of faith, or want of experience, the plan has never been adopted, although it has been tried repeatedly, in this country. The surgeons who practise this method write of it as follows:—

Davis, (a) the originator, says it occurred to him that if the principle of continued elastic extension "could be so applied as to allow the patient to walk and ride, and take out-door exercise, we should not only add to his comfort and happiness, but it would aid in invigorating the system, thereby enabling it not only to resist the disease, but to repair the injury that might already have been inflicted." And again he says:—"This we consider the essential element in the treatment of the disease under

consideration, viz., motion without friction, for no part of the anatomy requires motion to maintain its integrity more than the joints."

O. F. Taylor (a) observes "it is pressure or motion under pressure which is the destructive agent in disease of the hip-joint . . . and motion in the joint without pressure is not only not injurious, but is highly beneficial."

Sayre (b) writes:—"Motion is as essential in retaining a healthy condition of the structures about a joint, as light is essential in retaining a healthy condition of the eye."

All this is true. It is perfectly true that exercise is necessary to maintain the functions of a joint, but it must be a *healthy* joint. Friction in an *inflamed* joint may be followed by the most disastrous consequences. It is the fear of producing friction by the employment of this method that has hitherto prevented its use by British and Continental surgeons. The splints used in this method, especially that of Sayre, are frequently used in this country for a late stage of the disease, and when the patient is able to get about. Davis's splint consists of a metal rod, extending from the hip to the ankle along the outer side of the leg. It is interrupted about midway by a screw for regulating the length of the splint. To the lower end is attached the extending apparatus, and to the upper end the perineal band. The perineal band consists of an elastic layer and an unelastic layer, so that tension is constantly ensured. Sayre's splint is essentially the same as Davis's, but instead of extending to the ankle, stops short at the knee. In the use of this splint, the lower portion of the thigh encircled by two curved pieces of iron is made the point of extension, and the perineum under which is passed a perineal band is made the point of counter extension, tension is kept up by a rack work, moved by a key.

DYSPEPSIA—ULCER OF THE STOMACH. (c)

By DONALD W. C. HOOD, M.D. Cantab., M.B., M.R.C.P.,
Assist.-Physician West London Hospital.

IN this paper the author maintained that the more our experience of the natural history of disease increased the more we must accustom ourselves to the fact that dyspepsia should be looked upon as symptomatic rather than generic. He drew especial attention to those cases of stomach lesion in which dyspepsia plays such an important part as a symptom, and suggested that in many cases of so-called simple dyspepsia there was a definite lesion of stomach coat. He held that the carefully compiled category of symptoms incidental to ulceration of the stomach suggest that its diagnosis is easy, the very opposite of that being clinically the case. In the early part of 1879 he had placed under his charge, by Sir William Gull, a gentleman, æt. 40, who had spent many years of his life in the colonies, where he had spent sheep tracks. For eight years he had been a sufferer from dyspepsia, the commencement of which he attributed to irregularities of diet. He first felt pain over the region of the stomach, soon he suffered from attacks of vomiting, and acid water brash. Failing to obtain relief, he came to England. When first seen by him eighteen months after his arrival his symptoms were much intensified. He detected blood in his vomit. Presently the stomach became intensely irritable, the patient being supported entirely by means of nutrient enemata. Slowly the grave symptoms subsided, and he regained flesh. In six weeks he went about as usual. But three weeks afterwards, while sitting, on moving suddenly, he felt a pain in the stomach, and died within twelve hours. The post-mortem showed perforation of the stomach at its anterior base. A small healed ulcer, at its base no thicker than tissue paper, had given way, and the contents of the stomach had become extravasated into the peritoneal cavity. The most instructive part of the examination was the condition of the stomach in the immediate vicinity of the pyloric orifice, which was honey-combed with

(a) "On the Mechanical Treatment of Disease of the Hip-Joint."

(b) "Orthopædic Surgery."

(c) Read before the West London Medico-Chirurgical Society. Discussion on page 204.

(a) "Conservative Surgery," New York, 1867.

the remains of cicatrices of old ulcers that presented small depressions corresponding to the position of gastric follicles, which are in greatest abundance at the pyloric extremity. The condition of the mucous membrane appeared to supply abundant cause for all the gastric trouble which had caused so much pain during the preceding eight years. It happened that another patient, whose symptoms bore some resemblance to those of the case he had stated, was under his care at the same time. This was a German gentleman, *æt.* 40, who had suffered from painful digestion about fourteen years. In the early days of his illness he had felt pain after taking food. Later, he began to suffer from occasional attacks of vomiting. He had been repeatedly treated for dyspepsia. When first seen he was rather emaciated. The stomach usually emptied itself at the end of the day. On several occasions a coffee-coloured matter had been ejected, and altered blood was sometimes mixed with the vomit. The stomach descended below its natural limit, and a small lump could be felt in the epigastric region, indicating obstructive disease of the pylorus. Upon treatment, flesh was gained, the vomiting ceased, and the stomach recovered its natural size; but the lump remained. Subsequently he went to his business abroad, when the symptoms returned, and he died of exhaustion. Statistics proved that ulceration of the stomach was of very frequent occurrence, but beyond question the symptoms of ulceration varied very greatly. Although hæmorrhage was a symptom of the utmost moment, it was not judicious to wait for the presence of blood before inferring the existence of ulceration. All writers on the stomach treated ulcer as a chronic disease, but none of them advised such treatment as would be adopted in regard to an ulcer occurring on the surface of the body. In treating assumed ulcer he thought it imperative that the patient be kept in a recumbent position, in order that the stomach walls might be in a state of rest. Where there was much enlargement of the stomach he generally used a counter irritant, and he freely prescribed the various preparations of opium in those cases where there was no doubt that the dyspepsia did not arise from hepatic engorgement, as he found that it not only stimulated the bowels, but also made the patient intolerant of restraint. Such treatment in the early stages of dyspepsia was sure to result well. Where the presence of ulceration was well-marked such treatment should be resorted to as would be insisted on if the ulcer occurred on the surface of the body. He had found this method of treatment productive of the best results in the case of a lady, who, at the time of first seeing him, was afraid to take the simplest food lest its ingest should cause her pain. On making a careful examination of the abdomen he failed to find enlargement, but in the epigastric region there was a spot most tender on pressure. He ordered her to bed, recommended rich milk and light broth as diet, and prescribed six drops of laudanum every four hours. Iodine was suggested as a counter irritant. A simple soap and water enema was to be used every other day. From the first the patient's progress was satisfactory. Pain ceased, there was no vomiting, and the bowels acted regularly. She left her bed in fourteen days, and recently he received a letter stating that she was quite well. He regarded the case as representing ulceration or excoriation at that stage in which great good can be done by a decided course of treatment.

Clinical Records.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

Tubercular Meningitis.

Under the care of Dr. C. E. ARMAND SEMPLE.

MAY P., *æt.* 3½, admitted November 1st, 1882.

History.—A healthy child up till about 14 days before admission. Had measles about 18 months ago. Pertussis a year before this. The present illness began with fretfulness and cough. The father died on October 20, 1882, of phthisis. The eldest child is ricketty, and one other child died of inflammation of the brain. Mother healthy, except for occasional attacks of ague.

On admission.—A well-nourished child. Wrists somewhat enlarged. Tongue a little furred. Temp. 97.4. Percussion-note a little flattened over left base where breathing is hard. Slight rhonchus and hard breathing in left supra-scapular region. Heart sounds normal. Abdomen normal. Slight cough.

Urine contains urates. No albumen. Given a mixture of ammonia and ipecacuanha.

Nov. 12th.—No marked physical signs. Allowed to get up.

14th.—Temperature up to 100.8°. Face flushed. Throat injected. Given a hot bath and oleum ricini.

15th.—Rhonchi over lungs both sides, and in front. Temperature remains high (102°). Poultices to chest. Hot bath. Throat painted with glycerine and tinctura ferri perchloridi.

17th.—Throat still injected, and tonsils swollen. Painting continued. Occasional cough. Mucous râles all over chest. Sulphurous acid spray to throat.

22nd.—Temperature lower since last note. Crepitation back and front. Still coughs a good deal, and sweats at night. The tonsils remain swollen. Is rather irritable.

23rd.—Temperature again rising. Left tonsil a good deal swollen. Drowsy all day. Lies quiet, except when moved, when she cries. Face flushed. Perspires profusely. Seems unconscious. Moans occasionally. Icebag to head.

24th.—Still heavy and unconscious, with occasional moaning. Picking bedclothes. Pulse irregular. Not much cough. Marked *tâche cerebrale*. Face flushed.

Evening.—Lies with elbows and wrists flexed. Moans at times. Twitches occasionally. Takes milk well.

25th.—As before. Unconscious, with flushed face, and occasional moaning. Takes nourishment badly. Has not twitched so much. (For temperature, see chart.) To have nutrient enemata.

26th.—Breathing at 4 a.m. very embarrassed (occasionally Cheyne-Stokes in character). Skin over abdomen more inelastic. Foams a little at the mouth. Quite unconscious. First two nutrient enemata returned, others retained.

27th.—Breathing accompanied by bowing with lips, and moaning. Still foams a little at mouth. Occasional twitching. Occasional alternations of flushing of face, with pallor. Pupils respond very feebly to light.

Evening.—More restless. Has taken milk by the mouth. Moans when disturbed. Motion passed unconsciously.

28th.—Has taken nourishment better. Breathes more quietly.

29th.—Twitching on the right side. Moans a good deal. Perspires freely.

30th.—Seemed to stop breathing several times during the night. Takes nourishment badly. Looks blue and pinched.

Dec. 1st.—Lies with elbows and wrists flexed. Breathing irregular. Skin over abdomen inelastic. During the night the back became arched stiffly, as in *opisthotonos*. Moans a good deal. Not able to swallow. Pulse fluttering; too rapid for counting.

2nd.—Remained the same during night. Pulse still too rapid and fluttering to count. Wrists strongly flexed. No plantar reflex.

Died in the afternoon.

Autopsy, December 4th.—On removing the skull-cap, and dividing dura mater, a considerable quantity of fluid escaped. The pia mater appeared somewhat abnormally injected, but otherwise there was nothing marked, except along the sides of the median longitudinal fissure. Here, on both sides, were a number of small tubercular elevations, with lymph. On opening into the ventricles, a large quantity of fluid escaped. The white matter here was very much softened, easily breaking down under the finger.

Thorax.—No adhesions of pleura. Surfaces of lungs studded with small tubercles. A considerable number of left lung (about the size of a filbert nut) enlarged.

Heart normal. An ante-mortem clot in the left ventricle, which also contained fluid blood. Left ventricle enlarged.

Abdomen.—Liver engorged, otherwise normal.
Kidneys normal.
Spleen also studded with numbers of minute tubercular elevations.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND. OBSTETRICAL SECTION.

THE Obstetrical Section met in the College of Physicians on Friday evening, January 26th, Dr. DENHAM, President of the Section, in the chair.

EXHIBITION OF SPECIMENS.

Dr. ATTHILL showed a large subperitoneal fibroid which he had recently removed from a patient by abdominal section.

Mr. ABRAHAM showed a specimen of ectopia of viscera in a foetal male cat of about five weeks. The heart, liver, stomach, and greater part of the intestines were quite extruded from the body cavity through a nearly central opening in the abdominal wall. A few membranous shreds could be traced from the margins of the opening over the viscera. No other abnormalities, and the membranes were nowhere adherent. Mr. Abraham also showed an example of dichotomy in the left foreleg of a sheep. The bones of the two fairly-developed feet started from the carpus. They were subequal in length, but the outer one, probably the accessory, was the slenderer of the two, and wanted also some of its flexor and extensor tendons. A common integument covered both feet as far as the metacarpophalangeal joints.

Dr. W. J. SMYLY reported a case of

INDUCTION OF ABORTION AT THE FIFTH MONTH NECESSITATED BY HÆMORRHAGE.

He concurred in the opinions of Drs. Priestly, Ahlfeld, and others, that the indications for the induction of abortion as distinguished from the induction of premature labour had not been laid down with sufficient precision. He could not, however, agree with Schröder that the induction of abortion should never be necessitated in cases of hæmorrhage. Nor did he believe that where this was prolonged abortion necessarily occurred spontaneously. The patient was a pluripara, and since the occurrence of a previous miscarriage had suffered from symptoms of endometritis. In the month of February last she again became pregnant, and for four and a-half months subsequently she was subject to frequently recurring hæmorrhages, which at last became so frequent and so profuse as to necessitate the emptying of the uterus. Labour was accordingly provoked by the introduction of a sponge tent, and accelerated by Barnes' dilator. The ovum presented a peculiar appearance, owing to the enormously hypertrophied decidua, the result probably of the endometritis. The fœtus was of a size corresponding to the period of pregnancy, and showed signs of commencing decomposition. A large quantity of firm laminated clots preceded and followed the expulsion of the ovum. The patient died of septicæmia on the second day after delivery.

Dr. MACAN said that the induction of abortion was clearly indicated in certain cases. However, in cases of molar pregnancy of a certainly dead embryo the term "procuring abortion" was scarcely a right one. Strictly speaking, the term was only applicable where a diagnosis was made, the fœtus living and capable of going on to its full term.

Dr. BEVILLE agreed with Dr. Macan. Whenever excessive hæmorrhage threatened the mother's life in early pregnancy steps which should necessarily be taken to stop the bleeding were also those which would usually accelerate abortion. In the presence of great hæmorrhage such steps might be properly taken, even though the embryo could in no way be ascertained to be dead. Dr. Smyly's case did not seem to him one to which "induction of abortion" was applicable. It was rather one of a threatened abortion, in which the amount of bleeding rendered accelerative measures advisable.

Dr. MACSWINEY thought that in Dr. Smyly's patient conservative measures had been too long persisted in to the detriment of the mother. Abortion might justifiably have been sooner hastened.

Dr. A. HENRY said that in this class of cases expulsion of the ovum should be expedited with the view to stopping dangerous hæmorrhage and preventing an opportunity for auto-infection.

Dr. SMYLY, in reply, said that the case cited in his paper was not one of a molar pregnancy. Decomposition having only commenced in the fœtus, it could only have been dead for two or three days. Had abortion been brought on any sooner the fœtus might have been born alive. He still thought that the nature of the case justified the title of his paper.

Dr. C. E. FITZGERALD read a paper on

THE CONNECTION BETWEEN OCULAR DISEASES AND CERTAIN AFFECTIONS OF THE FEMALE GENERATIVE ORGANS.

The PRESIDENT said he had lately under his care a child of only eight years old who, he had no doubt, masturbated. She had never menstruated, and suffered from organic brain disease. One question was whether the practice was not sometimes induced by some derangement of the general health affecting the brain.

Dr. MACAN remarked that the question of masturbation was a most difficult one, and he hesitated to say what he heard about it. Without the patient's own confession they could not be absolutely sure about it, but there might be evidence sufficient for a moral belief. The symptoms which he took as signs of masturbation in an unmarried woman were flabbiness of the vulvæ, great relaxation of the parts, and the possibility of palpating the ovaries. He had in such cases palpated them with as much ease as in a woman who had had half-a-dozen children. Besides, there were the ravenous appetite, the muddy complexion, and the entire moral aspect of the woman which proclaimed the Onanist. It was necessary to get a confession from the woman, because treatment was powerless until they were able to tell her that the injurious practice must be stopped.

Dr. HENRY KENNEDY said that in his experience masturbation among females was very general, but had not found much difficulty in getting them to admit it. He had rather found that both males and females who were addicted to the practice would admit it if properly asked. The question of connection between such practices and diseases of the eye was a very difficult one, and almost required a man to be at once a specialist in two departments. The combined knowledge of oculists and gynecologists might determine the question. The immediate effects of the practice were confined to the external parts, and no disease in the proper sense of the term was set up in the vagina or in the uterus. The more remote effects were not confined to the eye alone. The disease *petit mal* had directly resulted from the habit in both men and women. He had cured *petit mal* in both sexes by insisting on the practice being given up. Amongst the signs were drooping of the eyelids, dilatation of the pupils, and complaints of loss of vision; and inquiries then generally elicited the fact that the practice was resorted to. He did not think that inspection of the vulvæ would make it certain that the habit existed. He had known hypertrophy of the parts to result from the practice.

Dr. MACSWINEY was sceptical as to the general prevalence of masturbation on the part of young girls. There should be the utmost caution before entertaining a question of the sort respecting a young girl brought to a medical man for advice. Downcast eyes and large pupils and muddy faces were not sufficient to justify the conclusion that an examination should be made. He thought the question with respect to that practice was whether it was a disease of the uterus or general organs. It might go on for years without any visible signs of the sexual organs at all. Did boys who masturbated suffer from analogous ocular affections?

Dr. BENSON said it was difficult to understand how so many eye affections as had been mentioned could be produced by one common cause, and it seemed more reasonable to suppose that both the masturbation and the ocular affection were in common the result of some nervous disease. They knew that a very large number of lunatics had been found to practise masturbation.

Dr. SWANZY said there were other irritations of the sexual organs besides the one mentioned which gave rise in females to diseases of the eye. In the end they might find that both the masturbation and the ocular affection were the result of one and the same cause—namely, an affection of the base of the brain. He had seen a patient in whom the menopause combined with mental excitement had applied to him to determine an attack of optic neuritis terminating in atrophy. In this case the cessation of the catamenia had appeared to act deleteriously, converting what had been previously an habitual congestion into an inflammation. Five years ago he read before the Obstetrical Society a paper in which he tried to

show that in young girls of from eleven to fifteen years of age cases of iritis occurred, that disease being very rare in such subjects except in cases of inherited syphilis. He had never seen a case of iritis at that time of life in a boy, and he could hardly believe that those cases of iritis were not due to some disorder of the generative system. Another very remarkable condition was hysterical amblyopia resulting from disorder of the uterus. There was a peculiar form of it which occurred in young girls presenting no ophthalmoscopic signs, but in whom central vision was very much decreased, and there was great contraction of the field of vision. He had under his care a case of that kind connected with the tardy appearance of the menses. She first came under his care, *æt.* 17, the menses not having then appeared, and her vision being much affected. In six months' time the eye symptoms were relieved. The other day, her age being 19, her first catamenia appeared, and she was then attacked with low vision and contracted field of vision, and now, after a fortnight or three weeks, she had quite recovered.

Mr. STORY said his impression was that nothing definite had been proved in this matter. That there was a connection between the uterus and the eye it was true, just as there was connection between the uterus and every other organ; but that there was any peculiar or functional connection he did not believe. It was proved, however, that disordered menstruation had an effect on the phenomena of vision, but besides anomalies of vision, it produced disorders in other portions of the system. He had never seen a case of hysterical amblyopia. He did not disbelieve in the affection, but he did not believe that it occurred without there being a definite physical cause for it. He could understand absolute loss of vision being produced by hæmorrhage upon some portion of the optic nerve behind the eyeball, which might afterwards be absorbed and vision restored. The proofs given in the paper of Dr. Mooren, which Dr. FitzGerald had made the basis of his paper, seemed to be unsatisfactory as regarded the alleged connection between affections of the uterus and affections of the eye. The process of causation assigned for the production of the affection of the eyes seemed most elaborate and far-fetched, and many of the cases quoted, when critically examined, failed to support his contention with cause and effect.

Dr. DOYLE had been startled by the statement in the paper as to the frequency of masturbation among females. He did not believe the connection between masturbation and eye affections to be made out on the evidence adduced.

Dr. NEVILLE objected to masturbation being regarded as a disease of the generative system. Was it a disease at all? He did not think it was. It was very often a vice, while in other cases it was symptomatic of disease rather than a disease in itself. Sometimes it originated in a local source of irritation, such as acrid discharges from the genital organs, or in boys by a long prepuce, while sometimes it was due to distinct or latent nervous diseases. Thus masturbation was associated with epilepsy and insanity, not in a causal relation, but as an individual symptom of the nervous disorder. It no doubt was often an early or premonitory symptom in such cases. Eye affections, such as atrophy of the optic nerve, were naturally here to be looked on as symptomatic; also it must not be forgotten that the apparent connection between affections of the generative system and of the eye might merely be coincidences. To prove the causal relation of the former it must be shown that they preceded the affections of the eye, that the menstrual molimina influenced the course of the eye affection, and also that their cure was essential as a part of the treatment, at least of the latter. It was certain that disease of the generative organs with disordered menstruation would react on a disease of the eye as on the rest of the system, but this reaction was not to be confounded with causation. Nothing had been proved to his satisfaction with regard to this alleged causation.

Dr. FITZGERALD replied, contending that Dr. Mooren's proofs in the form of cases had not been fully represented in the American translation; in the original German they were more full and convincing. The whole question was a suggestive one, and worth more extended study. But he had not meant to imply that there was any special eye disease set up by disease of the uterus or ovaries. He believed that masturbation induced eye disease in boys just as well as in girls.

The Section then adjourned.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

THE usual monthly meeting of the above Society was held on February 2nd., the chair being taken by Dr. Hart Vinen the President of the Society.

Dr. HOOD read a paper on

DYSPEPSIA—ULCER OF THE STOMACH,

which will be found on page 201.

Dr. DANIEL said that three or four years ago he attended a gentleman who had acted as special artist for the *Illustrated London News* in the Franco-German War. He was a fine muscular man, but had contracted indigestion. He gave calomel and colocyth. But the symptoms increased, the patient became very emaciated, vomited largely, and at last was unable to keep food on his stomach. No blood could be traced in the vomit. Dr. Gull was called in and inferred there was ulceration. He continued to get weaker, and became at last a mere skeleton. Enemas of nutritive liquids were given, but eventually he died of exhaustion. There was no post-mortem.

Dr. SCHACHT suggested that in addition to rest he regarded an enema every other day as important. Constipation was an awkward symptom, and the enema, by relieving the stomach, allowed the opium to do its work.

Dr. CAMPBELL POPE said that he overcame constipation with bismuth in conjunction with belladonna.

Dr. ORTON said that he knew of a practitioner who had symptoms of ulceration for thirty-five years, and who at last collapsed from vomiting. The post-mortem revealed ulcers in all stages.

Dr. HOOD, in reply, suggested that marked dyspepsia required the most careful examination, for early diagnosis was very difficult. The ulcers were really boils of the stomach resulting in choked glands. He was strongly of opinion that dyspepsia demanded vigorous treatment.

Mr. C. B. KEETLEY briefly mentioned a case of re-fracture after bony union of a fractured patella had been obtained, and

Dr. JAMES THOMPSON showed examples of the Beaufort artificial limbs, and explained their peculiarities and advantages.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, FEBRUARY 5TH, 1883.

JOSEPH WALKER, M.D., President, in the Chair.

Dr. WALKER, the newly-elected President, took his seat for the first time, and delivered his inaugural address, in which he reviewed the present state and future prospects of the Society, and suggested certain changes with the view of rendering the meetings more attractive and useful to the general body of the profession.

Mr. NATHANIEL STEVENSON showed an electric lamp for illuminating the cavity of the mouth, which had been made for him by the Swan Electric Light Company; the strength of the current, generated by a bichromate battery of four cells, was regulated by a very ingeniously-devised reostat of his own invention.

Mr. BOYD WALLIS exhibited another electric lamp of similar design and purpose, but the light was produced by the incandescence of a carbon filament *in vacuo*, instead of by the heating of platinum wire. In the latter case, if too strong a current was used the platinum would melt, and the lamp was thus rendered useless; hence the necessity for the ingenious but complicated reostat described by Mr. Stevenson. The carbon filament was practically indestructible, so that but little attention need be paid to the strength of the current. Mr. Wallis also showed a double induction electric motor, of American manufacture, which, with a six-celled bichromate battery, would run a dental engine or lathe at any speed required.

Mr. HENRY SEWILL then opened a discussion on the following question:—"Do the incontrovertible facts which we now possess as to its etiology and pathology fully account for the phenomena of dental caries?" He thought there could be no doubt that this question should be answered affirmatively. He had no hesitation in asserting that caries had been proved to be a disintegration of tissues due to the action of external causes. The fact that caries occurred in dead teeth, and in artificial teeth made of ivory,

was of itself sufficient to show that the disease was not of constitutional or local inflammatory origin. The chief cause of this disintegration was certainly *acid*, derived from the decomposition of foods, from deranged secretions, acid mucus, &c.; the predisposing causes were such as rendered the enamel and dentine more easily acted upon by acids, as fissures and malformations of the enamel, soft, badly-formed dentine, crowding and irregularity of the teeth, which favoured the lodgment of decomposing *débris*, and interfered with proper cleanliness, and anything which favoured the formation of acid within the mouth—as a bad state of the secretions, chronic dyspepsia, &c. Mr. Sewill then reviewed the authorities on the subject, showing that Messrs. Tomes, Wedl, Leber and Rottenstein, Magitôt and others all favoured the view that caries was the result of ordinary physical causes acting from without.

Mr. COLEMAN replied that if acid was the sole cause of caries, the result would be a more general action upon the teeth than was commonly met with. He had tested the condition of the mouth in some hundreds of cases of acute caries, but did not detect any unusual acidity. The statement that caries in living and in dead teeth was identical had been denied by some observers. Dr. Frank Abbott had asserted that he found distinct evidence of inflammatory change in carious dentine; and it appeared to be a fact that the changes found in carious cementum were similar to those which occurred in bone during the progress of undoubted inflammation. He thought also that the appearance of caries in previously sound teeth, which not infrequently occurred after severe illness, pointed to the influence of a constitutional, and not merely a local cause.

At this point the discussion was adjourned until the next meeting.

The Services.

OUR SOLDIERS IN INDIA.

The Indian Government has at last placed its stamp of condemnation on the system of short service in the ranks of regiments serving under its jurisdiction. The proceeding is somewhat an expensive one, for, as we learn a bounty of fifty rupees—that is, the nominal equivalent of £5 is given to every soldier who, after completing six years' service in that country, consents to prolong his service to a total of eight. The number of British troops required to garrison India has been definitely fixed at 60,000. In 1877 it was considered that the "strength" of the force there had been reduced below the line of safety, for regiments and drafts, consisting of weakly boys and youths, were then sent out from England to take the place of older men who were sent home. It was then no uncommon thing to have a considerable number of such "white stuff," as similar material was called in America during the late war, sent direct from the transports in which they reached Bombay, to Hill stations where they were retained for a longer or shorter period, carefully fed, and otherwise "nursed," as it were, until fit to perform military duty. No doubt an attempt was made to remedy this state of affairs, and "old" soldiers, such as they were, were sent to India in as large numbers as were available. But under the short service system, then in full operation, such men were not to be had to any considerable extent, and the consequences, bad enough as things were, would have been serious indeed had not peace been prevailing. When the following year the war in Afghanistan occurred the sad consequences in life of men which happened among the young soldiers may be gathered by men who know how to translate the language of statistics. By a general order just issued by the Horse Guards' authorities, the length of service in the ranks is to be extended to twelve years. So far, so good. The urgent recommendations of old officers of experience are, perforce, being attended to. But the measures thus being gradually and grudgingly adopted must, in their

fulness, be re-introduced; service in the army must once again become a life-long profession; the soldier have not only all the advantages which seeing that a man in his social position is reasonably entitled to, but also the prospect of pension sufficient to keep him from the poorhouse, and from poverty in his declining years. England prides herself on her wealth and on her liberality. Let the latter be shown as it ought to be towards her soldiers and her sailors.

ALDERSHOT DIVISION.—Surgeon-General R. Gilborne has been appointed to succeed Surgeon-General J. Sinclair as Principal Medical Officer to the Aldershot Division.

ARMY MEDICAL DEPARTMENT.—Brigade Surgeon George Whitla has been granted retired pay, with the honorary rank of Deputy Surgeon-General.

BENGAL MEDICAL ESTABLISHMENT.—Brigade Surgeon Robert Faure Hutchinson, M.D., to be Deputy Surgeon-General.

MADRAS MEDICAL SERVICE.—Surgeon-Major Henry King, to be Brigade Surgeon.

NAVY MEDICAL SERVICE.—Fleet Surgeon John Money Shaw, C.B., has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet, with seniority of 16th ult. The following appointments have been made:—Staff Surgeon James Dunlop, to the *Opal*; Surgeon Edward J. Biden, to the *Opal*; Surgeon Edward A. Lucas, to the *Forester*, vice Biden.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

TYPHOID FEVER.—Dr. Jaccoud, the eminent professor, and editor of the celebrated *Nouveau Dictionnaire de Médecine et de Chirurgie*, gave before the Academy de Médecine an *exposé* of his treatment of typhoid fever during the last sixteen years. His treatment consisted of two parts, the one constant, comprising alimentation with beef-tea-wine, and above all, milk, of which he gave two quarts daily. Independantly of its alimentary properties, the milk had a direct effect, which warded off every special complication that might have resulted from a deficient renal excretion. Besides, he gave from one to two ounces of alcohol daily in a mixture, to which was added a drachm of extract of cinchona. When the temperature was a little above the normal he ordered cold sponging with aromatic vinegar four times a day, or oftener if the temperature rose to 102° or 104°. He found that these lotions not only produced an antithermic effect at the moment, but that the refrigerating effect became permanent after two or three days. Such was the constant treatment of typhoid fever from beginning to end. However, whenever the fever ran very high, and the action of the heart was weak, Dr. Jaccoud gave in small doses the bromo-hydrate of quinine or salicylic acid, the antithermic properties of which he found to be about equal. However, the salicylic acid being antiseptic, Dr. Jaccoud gave it the preference, provided that none of the following counter-indications existed: Alcoholism, violent headache, or delirium, weakness of the heart's action, or grave affection of the kidney. As to the result of this treatment, the statistics are very clear and satisfactory. In sixteen years, Dr. Jaccoud treated 655 cases, out of which he lost 71, or 10 per cent., whereas the average mortality in this disease amounts to 19 per cent.; consequently he had

good reason to congratulate himself. In concluding, the learned professor attacked with great vigour the tendency of these last years to give excessive doses of those medicines considered as antifebrile or antiseptic. The "new lights" of the day directed their whole treatment to kill the microbe which is said to be the real cause of the malady; but in their efforts in this direction they forget or ignore the condition of the patient, whose stomach is not able to tolerate the abuse that is made of salicylic or phenic acids, and the result is, that if they succeed in destroying the bacterides, they also succeed in losing their patient.

SULPHATE OF QUININE AS AN ANTI-PYRETIC AGENT has frequently formed the subject of controversy at the meetings of the medical societies of late, and the diversity of opinions expressed as to its physiological effect on the animal economy, and especially as regards the circulatory apparatus, impressed M. Germain Sée with the idea of making experiments on animals and man with the view of establishing the opinion he expressed as to its action in typhoid fever. Sulphate of quinine, he found, produced only a very slight lowering of the temperature in the healthy man—the pulse gets slower and the blood pressure lowers. In the typhoid, the temperature lowers after the first twenty grains, and markedly so after forty grains, and the effect lasts a day and a-half. The sphygmograph gave very precise and precious indications of the effect of the alkaloid. Twenty typhoid patients were submitted to the influence of quinine, and the tracings of the sphygmograph showed that the double beat, or dirotic pulse, disappeared, and that the contractile force of the heart was increased. This remarkable property of quinine was observed in all cases. The thermometer, also, showed a direct decrease in the temperature. The conclusions of M. Sée were consequently entirely in favour of quinine, which he considered a powerful antipyretic, and of invaluable service in continued fevers.

WHOOPING-COUGH.—M. Dujardin-Beaumez gives a table or a dessert-spoonful, according to the age of the child, of the following mixture in whooping-cough, night and morning:—Bromide of potassium, 30 grains; bromide of sodium, 60 grains; bromide of ammonium, 30 grains; chloral, 20 grains; water, 4 oz.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Brighton 13, Derby 14, Plymouth, Bristol 17, Portsmouth, Salford 19, London, Edinburgh 20, Birkenhead 21, Halifax, Oldham 22, Birmingham, Newcastle-on-Tyne, Cardiff, Norwich, Huddersfield, Bradford, Leeds, Leicester 23, Nottingham 25, Sheffield, Preston 27, Liverpool 28, Manchester, Sunderland 29, Hull 30, Blackburn, Bolton 31, Wolverhampton 32, Glasgow 33, Dublin 35.

THE death-rates last week in the principal large towns from diseases of the zymotic class were again low. The highest rates per 1,000 were—From whooping-cough, 1·8 in Derby and 3·0 in Hull; from scarlet fever, 1·8 in Birkenhead and 1·9 in Leeds; and from fever, 1·2 in Birkenhead, 1·3 in Sunderland, 1·4 in Liverpool, and 3·8 in Blackburn. The 51 deaths from diphtheria included 18 in London, 10 in Glasgow, 4 in Edinburgh, 3 in Nottingham, 2 in Portsmouth, 2 in Sunderland, 2 in Newcastle-on-Tyne, 2 in Cardiff, and 1 in Dublin. Small-pox caused 8 deaths in London and its outer ring of suburban districts, one in Portsmouth, one in Hull, and one in Newcastle-on-Tyne.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 7, 1883.

A MERCANTILE MARINE MEDICAL SERVICE.

IF, as there seems good reason for believing will be the case, the agitation in favour of revision of the whole system of medical service on board ocean-going steamers which Dr. Irwin has for some time past been promoting, should terminate in the accomplishment of his designs, a vast and incalculable benefit will be conferred on a class of the population hitherto most inadequately provided for. In a previous article on this subject, published in our issue of January the 3rd, we insisted on the necessity for very material amendment of existing regulations under which ships' surgeons are called on to discharge their onerous duties; and as since that time the efforts made to secure such improvements have been continuously advancing, the question has now assumed a phase that entitles it to renewed consideration.

It is unnecessary, however, to recapitulate in this place the lengthy list of evils which are constantly being reproduced on almost every vessel that leaves our shores; evils which, when most dispassionately reviewed, cannot fail to stir a feeling of indignation that they have so long been permitted without authoritative interference from reformers. However true it may be that rules relating to medical officers in charge of floating populations were framed in accordance with

precautions sufficient to protect the public interests at the period of their enactment—and to the solidarity of which we should certainly take exception—it is nevertheless unmistakably evident that they are wholly inadequate to meet the conditions imposed by such unprecedented developments of emigration traffic as have marked the interval since these rules were formulated in 1856. Now both in point of numbers and importance the crowds who make lengthened voyages in the “liners” specially devoted to such departments of the carrying trade, are infinitely greater than was the case fifteen or twenty years ago, and hence it must be that measures insufficient to meet the demands set up by the lesser need are signally incompatible with requirements created by a growth altogether unanticipated.

The ultimate end to be attained will only be accomplished when the medical service of the mercantile marine shall be firmly and unassailably fixed by law on a basis of honourable responsibility; and it is for this desirable end that energetic attempts are at present being directed to arouse interest in those quarters from which alone the necessary powers can be derived. In order that human life shall be properly protected, and especially the lives of very young and of more weakly and elderly passengers, it is essential that the task of caring for them shall be remitted to competent and independent officials; and a primary element of success in this connection is that every such official shall occupy a position subordinate, so far as the duties of his especial office are concerned, to no other authority whatsoever. There is, unfortunately, abundant cause for the belief—indeed, the knowledge we possess in the matter does not admit of any doubt respecting it—that, with scarcely a single exception, surgeons on board ships are in effect regarded as of no more consequence than any one of the captain's subordinates. Nor is this the only intolerable part of the arrangement which now holds, for in every detail of hygienic management the authority of the captain reigns superior to that of the surgeon, who is by education and training in such affairs necessarily more competent to judge what should and should not be permitted with a view to healthy surroundings. It can be no possible indignity to the commander of a vessel that he should be required to abstain from participation in directing in regard to measures calling for skilled knowledge, the acquisition of which has never been expected from him; and it cannot but be to the interest of all concerned that no part of the captain's time or attention should thus be taken up in discharging duties other than those incident to the sailing management of his vessel, and the maintenance of discipline among his crew.

But for the fact that usage accustoms to any enormity, it would seem manifestly unfair to ask from a captain such labours as he is accustomed to bestow on details of hygiene; and once the real nature of this question is aptly appreciated, there is little fear that objections will be raised to a reform which will carry with it a much needed relief of burdens. Owners, however, may be expected to look with an eye of disfavour on the impending change. The pocket element, an important one here as everywhere, is directly interested in a permanent establishment of the *status quo*; and the

strength of opposition will be experienced from quarters which will appear to be first affected by the called-for alterations. The creation of a Government class of mercantile marine medical officers will at once give to ship surgeons a professional status of a nature in agreement with the enhanced responsibilities they will sustain. The members of it also, we may be sure, will be required to possess something more than the questionable qualification of “physician, surgeon, or apothecary,” exacted by the law at present; they will have to produce evidence of higher value than this, and proof also of their fitness to be entrusted with the charge that will be committed to them. In a word, they will be highly educated and skilled practitioners who have shown themselves to be possessed of readiness in capacity for the treatment of disease, and the preservation of health under such abnormal conditions as ordinarily exist on board a crowded vessel of the tonnage common among the numerous fleets of ocean steamers nowadays. The services of such men must be appropriately paid, and the rate of remuneration must be fixed in a way that will leave no possibility of diminution in response to an owner's exactions. Whether it be at the rate of £300, or £400, or £500 a year is for future consideration and decision; but at least it must be fairly proportionate to the value of services in return for which it will be paid. By this means alone can the objectionable practice of presents from passengers to medical officers be once for all abolished, a practice which is at once derogatory to the profession, and, we think, has in no small degree tended to the formation of an improperly low estimate of the social status of ship surgeons.

We need not enter on the question as to how owners shall recover all or part of the additional outlay they will have to make in surgeons' pay. Whether by raising their passage rates, or by requiring all but steerage passengers to pay for medical attendance, is immaterial; for at the worst, the increase to them can be only trifling.

There is an important point, however, that deserves brief consideration; and that is, the advisability of providing in the scheme for creating a mercantile marine medical service, for a sort of apprenticeship by every candidate for the post of ship surgeon. Under the new regulations these posts will be desirable and honourable openings to practice; and it will be reasonable and right that every surgeon who aspires to obtain them shall prove his fitness for the duties they involve, by passing at least one year as assistant-surgeon on board. He will thus gain a most essential knowledge of the life he will subsequently be called upon to lead, of the nature of his work in the responsible position of medical attendant, and of those innumerable practical details that are special in every sphere of perfect usefulness. He will also obtain very valuable information concerning his own physical fitness for sea living, and for working amid the surroundings encountered in vessels. Too many surgeons have experienced, when out at sea, the fact that they are totally unfitted for the work they have undertaken; and with what possible disastrous results to those in their charge may be only too vividly imagined.

We most earnestly hope that Dr. Irwin and those who are working with him in this matter may be entirely successful in their aims; for by the proper limitation under Government warrant of the duties, position, qualification, and pay of ship surgeons, an incalculable amount of benefit will be conferred on hundreds of thousands of human beings annually.

PULMONARY SYPHILIS.

THERE are few diseases whose pernicious influences on the system are so universal and so diversified as syphilis. Its poison seems peculiarly inimical to fibrous structure, and consequently to the minute blood-vessels, and to the organs in which they ramify to the greatest extent. Certain recent works on this important subject have revived the interest in it, which all physicians must feel; for example, the compendious memoir of Pancritius, the carefully studied thesis of Carlier, and a series of communications made during the past five years to the Société Anatomique of Paris. These works examine exclusively the question of pulmonary syphilis in the adult. Pulmonary syphilis in the new-born is a subject totally *sui generis*, whose features have been grasped scientifically since the time of Cruveilhier, by such authorities as Baron, Billard, Husson, Virchow, Cornil, and Ranvier, &c. All these authorities have reasonably concluded that the phenomena of infantile pulmonary syphilis are so characteristic that it is impossible to confound them with those of any other affection. But, if on this subject, from the point of view of pathological anatomy, so much precision has been attained to, it is quite otherwise with the specific pulmonary affection of the adult. Not a few physicians have hesitated to acknowledge their existence, while some have even totally denied them. Paré, Baglivi, and Astruc conceded that syphilis might originate destructive alterations of lung tissue, to which phthisis would form the *role* of a *secondary diathesis*, an influence, they also maintained, common to blenorrhagia. In short, the specific nature of pulmonary syphilis has been but very tardily accepted by the profession. Morgagni was an avowed partisan of the pulmonary syphilitic doctrine, but sufficiently authentic proofs thereof failed him. At the commencement of the present century Lammonier affirmed the existence of a phthisis of a syphilitic nature, and curable by the ordinary anti-syphilitic treatment. During the period of thirty years commencing with Lænnec in 1804, and which may be regarded as the Renaissance of pathological anatomy, syphilis was almost forgotten in this connection. Perhaps this was in great measure due to the influence of John Hunter, who scarcely believed in any visceral complications of syphilis. It was not until 1826 that Lænnec and Andral described and recognised syphilitic phthisis. Van der Kolk maintained that syphilitic subjects sometimes died presenting "phthical appearances, with ulceration of the lungs, situated most frequently in the middle lobe, but without tubercle." To Ricord is mainly due the recognition of syphilitic phthisis as one of the most certain and incontestable sequences of venereal infection; and Gilbert, Fournier, and especially Lance-reaux have substantiated by pathological anatomy, not

only the possibility but even the frequency of syphilis of the lung. The microscope has afforded in this investigation less assistance than one would, at first thought, be led to anticipate. The structural changes of a syphilitic lung appeared only as common inflammatory changes, and no light was thrown on the original specific nature of the process. Hence consideration of the larger lesions, and the history of the special case furnished the only reliable elements of diagnosis. In the lungs, as elsewhere, the histological changes initiated by the syphilitic virus consist of nodes and scleroses. Most frequently the scleroses are superficial; they are pleuro-pulmonary, and appear as elongated depressions, more or less deep, and more or less bound down with bands. These depressions are, however, seen in the most characteristic form in the liver and spleen. From the surface of the lung these fibrous bands penetrate the parenchyma of the organ, and radiate towards the hilus, as the septa of the testicle towards the body of Highmore. The *gummata*, on the contrary, are almost invariably situated in the deeper structure of the lung, and especially around the greater bronchi. Not frequently numerous, they have a firm consistence, are of a yellowish colour, and of a peculiar dryness, which distinguishes them from the great bulk of other morbid products. Their size is variable, but they seldom exceed that of a hen's egg. As a rule, they co-exist with sclerous induration of the parenchyma, and are encysted in fibrous rings or spheres. The large bronchial tubes are frequently ulcerated, and passage is thus sometimes afforded to the caseous substances of which the gummata are composed. In view of all the circumstances it appears that syphilitic gummata of the lung manifest a preference for the region of the hilus, from which they spread from within outwards, towards the deeper structure of the parenchyma. It may, indeed, be questioned if this anatomico-pathological variety of gummatous degeneration may not be regarded as a kind of peribronchic mediastinitis, seeing that, in a state of disease, pulmonary lobules of the fifth and sixth division may be recognised by the naked eye, and only of about the third and fourth in health.

From the clinical point of view, certain important deductions are to be drawn from these considerations. The great difficulty of diagnosis consists in differentiating between lesions which are syphilitic, and those which are tubercular. These lesions are equally distinctive, the physical signs which accompany them are identical, the phenomena of genuine consumption are present—such as broncho-pneumonia, bronchial catarrh, and hæmoptysis—equal in quality and quantity, only the topographical distribution of the gummata and tubercle is different; for while the former show a preference for the region of the hilus, the latter does for the apex. It is asserted that in pulmonary syphilis hæmoptysis is more rare and less abundant than in phthisis; but this observation is not borne out by reliable experience. Again, in how many instances do patients die of phthisis who have never spat blood?

It is thus evident that in the presence of a destructive centre in the middle portion of the lung there is some excuse for uncertainty or timidity of diagnosis. But if, as almost invariably happens, that in the event of death

from syphilitic phthisis, there exist specific lesions in the other viscera, especially in the kidney, in the bones, or on the surface of the body—if these lesions are manifestly recognisable as characteristic of syphilis, if the seat of the pulmonary destruction is other than what obtains in ordinary phthisis, there is almost incontestable proof that the initial stage has been syphilitic. In view of the signal amenability of syphilitic affections to proper treatment, it is obvious that the diagnosis of syphilitic phthisis is of the first importance; and to correct diagnosis may fairly be attributed the rarity of autopsies revealing visceral syphilitic lesions, and the *hiatus* that thus exists in visceral syphilography.

HAS THE PROFESSION SANCTIONED COMPULSORY NOTIFICATION?

We pointed out last week the falsity of the statement which has been so frequently repeated by Dr. Littlejohn and other sanitarians, that Parliament had critically examined into the arguments for and against compulsory notification by the physician, and had thereupon concluded that the general enactment of such a system was expedient. We showed that, so far from this being the case, compulsory notification has *never yet been discussed in Parliament* at all, nor has any opportunity ever occurred for submitting the proposed law to legislative criticism, and that in each and every case the notification clauses have been schemed through the House of Commons concealed amongst a mass of local regulations for the making of roads, laying down of water or gas pipes, or other civic improvements in which no one takes the least interest, and very few have the least knowledge, save the Corporate officials of the town to which they apply. But also we find the statement made with equal audacity and persistency by the compulsionist party that the medical profession is, in great majority, in favour of compulsory notification, and satisfied as to its efficacy. To this assertion we give the most unqualified denial, and we declare that up to the present time compulsory notification by the physician has not had any medical sanction whatever. It is true that up to last year it was warmly advocated by the Chairman of the Parliamentary Bills Committee of the British Medical Association, and by an earnest minority of sanitarians, members of the same committee, but it has never received the *imprimatur* of the Association nor the official approval of any one of the representative organs of medical opinion in the Kingdom. The early history of the agitation of the subject within our profession is given by Dr. Carter, of Liverpool, in a recent pamphlet.

The first intimation, he says, of the adoption of the principle by the Parliamentary Bills Committee was given in the report of its meeting on March 19, 1879. The Corporation of Leicester were about to apply to Parliament for compulsory powers. This application was opposed by the entire profession of the town, and, naturally, judging that the source to apply to for assistance in their struggle was this Committee, they wrote to the Parliamentary Bills Committee for help. The result must have been disappointing. As the reply to their appeal for aid, a resolution was forwarded, which had been

moved by the Chairman of that Committee, and seconded by a gentleman who was actually not a member of the Committee, in which it is stated that "it (*i.e.*, the Committee) is of opinion that such notification should be made *compulsory* and formal by the medical man to the family or guardian," who should then notify it to the authority.

Of course it will be thought that a principle of this kind—one so novel and so entirely subversive of the confidential relations hitherto existing between medical men and their patients—must have had the unanimous sanction of the Association before it was adopted, or at least must have been proved to be acceptable to the majority of medical men throughout the kingdom. In their report for the present year the Committee stated that they have acted *ministerially* only. The Registration of Disease Committee, to which the Parliamentary Bills Committee makes frequent reference, had never sanctioned the principle of compelling *medical men* to notify. Clearly, therefore, the Association had not up to that time sanctioned the principle of compulsion. Yet on November 7th of the same year, at a meeting attended by ten gentlemen only, it is decided "that the Chairman's Report be received and adopted, and that it be circulated amongst sanitary authorities and others interested in the subject."

And forthwith, without the sanction of any higher authority, without a word of assent from the Association, without so much as asking their assent, this Committee *did* distribute the Report, and *did* offer their assistance to sanitary authorities through the country in their efforts to impose fine, and in the last resort something worse, on the entire body of general practitioners if they should decline to do what most of them thought it would be wrong to do.

The condemnation of the proposal by the medical profession dates from the time when its details, which had previously been kept carefully secret by those who ought to have been the first to give warning, were made known to that profession upon the introduction, three years ago, of the Bill of Mr. Gray, M.P., to extend the system to Ireland. On that occasion the measure was critically examined, and the alarm sounded by the *Medical Press and Circular*, and at the meeting of the British Medical Association at Ryde in 1881, a resolution in favour of compulsion moved by Mr. Michael, Q.C., was rejected after a brief debate. But brief as the discussion was, it was sufficient to arouse the assembled physicians to an appreciation of the fact that a great danger was impending—that the true interests of sanitation, and of the profession, were likely to be sacrificed to the enthusiasm of fad-mongers, and that those whom they had trusted to protect them against the invasion were party to the transaction. In the succeeding year the opposition to the programme of the notificationists gathered strength, and last year at Worcester a definite resolution condemnatory of the system was passed in the teeth of the Parliamentary Bills Committee. In Ireland also, the Irish Medical Association has debated the matter in most formal and judicial way, and has declared, with overwhelming voice, against the proposal to make the physician the notifier. The Dublin Branch of the British Medical Association, originally led by the Chairman of the Parlia-

mentary Bills Committee to a quasi-approval of the system, has declared in favour of householder notification; while the Belfast and Cork Branches have passed resolutions condemning earnestly the proposition for compulsion.

We have shown that the principle and practice of physician notification has never been discussed in Parliament, and that, where it has been considered by the medical profession, it has been unanimously condemned. But we shall, no doubt, be answered that the Select Committee of 1882, on the police and sanitary clauses of the eight private Bills, did investigate the subject, and, thereupon, gave its judgment in favour of physician notification. We are therefore called upon to inquire: How far is the decision of this Committee worthy of confidence? And to what extent should it be regarded as an official pronouncement in favour of compulsion?

As we have said, this committee was not appointed to discuss the propriety of compulsory notification; it was nominated at a moment's notice by Sir William Harcourt for the purpose of checking the headlong aggressions of private Corporate Bills, and preventing powers being thus secretly obtained for objects altogether outside the ostensible purpose of those Bills. No notice was given of its appointment which could have enabled either the public or the medical profession to intervene for the purpose of securing independent representation on it. The notice of the appointment of a committee was given on the 11th of March and resolved upon on the 13th. The Committee was nominated on the 14th, and sat for the first time on the 23rd. It consisted of seven persons, viz.—Mr. Charles Parker (Perth), Mr. Henry H. Fowler (Wolverhampton), Mr. Garnier (Devon), Sir Gabriel Goldney (Chippenham), Mr. Hastings (Worcester), Mr. McLaren (Stafford), and Mr. Sclater Booth (Hants).

Be it observed that not one of the medical members of the House, nor any member who had identified himself in any way with the views of medical men on this subject had a place on the Committee. Dr. Lyons, Dr. Farquharson, Sir Trevor Lawrence, Mr. Meldon, and Mr. Gray, all of whom had interested themselves in the question, were carefully excluded, but their places were occupied by Mr. Hastings—the leader of the compulsionists—and Mr. Fowler and Mr. Charles Parker, well-known disciples of the same school, and the chair was occupied by Mr. Sclater-Booth, ex-President of the English Local Government Board—the department which, as we have pointed out, had collected from the mouths of town clerks and medical officers of health the whole case in favour of compulsion. Of the seven members of the Committee but four were present when the report was discussed, and three of these gentlemen, Messrs. Hastings, Fowler, and Parker, formed the majority on whose dictum it is now sought to impose the duty of compulsory notification on the physician.

This decision, such as it is, was arrived at, we assert, upon evidence totally insufficient and absolutely one-sided. The Committee had power to call for any evidence and any documents they pleased, yet they never heard the evidence of a single medical man, save three unknown persons, and one medical officer of health, who were brought up by the local Town Councils who promoted two of the Bills. Nay,

more! We believe that the evidence of Dr. Carpenter, the well-known sanitarian of Croydon, was tendered and refused, and we find it subsequently enunciated by the Committee that it "had no authority to call evidence against the clauses."

Upon what evidence, then, did the Committee form its judgment? Upon none whatever, save the return sent in by the Local Government Board, to which we have already referred. The compulsory notification clauses were brought up "cut and dry" by Mr. Michael, Q.C., Mr. Hastings' lieutenant in the invasion, and their adoption is officially reported as follows:—

Paragraph 3, *amended*.—Amendment proposed, at the end of the paragraph to add the following words:—"The Committee are of opinion that a large number of the Clauses in such Bills deviating from the general law are inserted without the knowledge of the inhabitants of the districts who would be affected by such enactments, and who have had no adequate means of making themselves heard against such Clauses; and, in point of fact, are generally unaware of the nature or effect of such Clauses"—Mr. M'Laren.—Question put, That those words be there added.—The Committee divided:—

Aye, 1.	Noes, 3.
Mr. M'Laren	Mr. Hastings. Mr. Henry H. Fowler. Mr. Charles S. Parker.

Paragraph 12 read.—Amendment proposed, to insert the words, "have had no authority to call evidence against the Clauses, and have relied to a great extent upon the fact that the Local Government Board are in favour of sanctioning provisions of law on this subject, at least in the more important urban sanitary authorities"—(Mr. M'Laren)—instead thereof.—Question put, That the words proposed to be left out stand part of the paragraph.—The Committee divided:—

Ayes, 3.	No, 1.
Mr. Hastings. Mr. Henry H. Fowler. Mr. Charles S. Parker.	Mr. M'Laren.

Paragraph *agreed to*.

If the approval of compulsory notification by Messrs. Hastings, Fowler, and Parker, upon the hearing of the evidence of one side only, is to be regarded as a grave and deliberate decision by Parliament, so may the resolution after of the Parliamentary Bills Committee of the British Medical Association, to accept the cut and dry report of their chairman, be received as the verdict of the medical profession. But this latter decision has already been reversed by the Association at large, and so, we hope, will the decree of Messrs. Hastings, Fowler, and Parker be dealt with when the truth comes to be known by the House of Commons.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 36, Bombay 29, Madras 40, Paris 27, Geneva 21, Brussels 22, Amsterdam 31, Rotterdam 30, The Hague 29, Copenhagen 26, Stockholm 31, Christiania 14, St. Petersburg 39, Berlin 26, Hamburg 26, Dresden 25, Breslau 31, Munich 27, Vienna 33, Prague 39, Buda-Pesth 31, Trieste 27, Rome 24, Venice 32, Lisbon 29, New York 23, Brooklyn 20, Philadelphia 24, Baltimore 29.

Notes on Current Topics.

Testimonial to Prof. Erichsen.

On Saturday next, March 10th, a meeting will be held in the Botanical Theatre of University College, for the purpose of presenting a testimonial to Mr. Erichsen, who has so long been directly associated with the educational work of University College and Hospital. As might have been anticipated, the efforts of the committee appointed to raise this tribute to a well-known and respected representative of English surgery, have met with prompt and signal success, and we doubt not that subscribers to the fund will unite with much heartiness in testifying by their presence at the meeting referred to, to the high esteem with which they regard the author of "The Science and Art of Surgery." Mr. Erichsen has done so much to make himself familiar both to those of a past as well as the present generation of practitioners, that nothing but satisfaction will be experienced at this new proof of the regard in which he is held. As a practical surgeon, as a teacher, and as an examiner he is universally, and even affectionately, esteemed, his invariable kindness and courtesy in the last-named capacity being not the least conspicuous of his good traits. At the meeting convened for Saturday next the chair will be taken, at 2.30 p.m., by Mr. John Marshall, F.R.S. The testimonial is in the form of a marble bust of Mr. Erichsen, modelled by Mr. Hains Thorneycroft, A.R.A., and we learn that its destination is the Anatomical Museum of the University College.

A Living Museum of Heart Pathology.

DR. STANISLAUS BIANCHI, anatomical practitioner of the University of Sienna, has printed in the *Bologna Revue Clinique* some notes on the numerous anomalies presented in the heart of a young girl who died on the 27th of March, 1882, from defects in respiration and circulation. The post-mortem examination showed the following peculiarities:—1. Chronic pericarditis; 2. General eccentric hypertrophy of the heart, especially of the right side; 3. Dilatation of the right auricle; 4. Slight tricuspid insufficiency; 5. Communication between the auricles by the foramen ovale; 6. Extensive communication between the ventricles caused by the almost total absence of the intra-ventricular wall; 7. Communication between the tricuspid orifice and the left ventricle; 8. And the mitral orifice with the right ventricle; 9. The pulmonary artery with the left ventricle; 10. The aorta placed in front of the pulmonary artery; 11. The anatomical characteristics of the left ventricle showed themselves in the right one, and vice versa.

Another Spurious Practitioner Fined.

As every case in which due punishment is meted out to fraudulent pretenders to medical qualifications may be regarded as serving to educate public opinion respecting the dangers arising from such practices, we may well feel satisfied at the frequency with which prosecutions have recently been recorded in this connection. The latest addition to the list is that of a Mr. John Mitchell Rhodes, summoned to the Otley Police Court, and fined £20, for using the title L.S.A., without being legally entitled to

do so. The facts are fully reported in the *Wharfedale and Airedale Observer*, for February 23rd last, from which we learn that Rhodes, having obtained the title of Associate of Apothecaries, has been for some time practising as a surgeon on the strength of it, and had signed about a hundred certificates with the addition to his name of L.S.A. The accused pleaded guilty, when, by an arrangement agreed to by both sides engaged in the case, it was settled by infliction of a fine to the full amount named above.

Irish Poor-law Reform.

Two gentlemen, possessed respectively of the patronymics of Megaw and Macaffee, and of the dignity of guardians of the Ballymoney Union, have decided that they will settle the difficulties of Irish pauperism. Accordingly, they persuaded the Ballymoney guardians to adopt a series of resolutions in favour of a general abolition of work-houses and other existing paraphernalia of poor relief in Ireland. *Inter alia*, they set themselves in arms against the superannuation of union officers, as to which they reasonably hoped for plenty of disciples, considering that the paying away of money for that or any other purpose is decidedly objected to in Ballymoney and most other places in the North of Ireland.

A great Megaw and Macaffee demonstration, or conference, was convened, and Lord Waveney was secured for the chair. The result would seem to have been rather disappointing to the two great men. Not one of the five resolutions which embodied their views was passed by the assembled representatives of boards of guardians, who, with difficulty, were induced to allow those resolutions to be sent round, without their *imprimatur*, for consideration of guardians elsewhere. Still more disgusting to the Megaw-Macaffee promoters is the circumstance that when their own resolutions came back to their own Board of Guardians at Ballymoney, they were distinctly repudiated by that board. However, we suppose these two gentlemen have acquired the notoriety they desire, and have, in the presence of a real Lord, delivered themselves of the speeches they had prepared, so that they perhaps rest satisfied and willing to leave the reconstruction of the Irish Poor-law to those who know something about it.

The Irish Poor-law Officers' Association has, by circular to all boards of guardians, conclusively disposed of the resolution drawn up by the twin legislators, in *re* superannuation, by pointing out that the statement therein, as to the nature of the legislation, is totally incorrect.

We are bound to suppose that Messrs. Megaw and Macaffee had never read the report of the Select Committee on this subject which sat last Session, and had no later information on the subject than that of twelve months ago.

WE regret that the funds of King's College Hospital continue to be in a very impoverished state, and that between £5,000 and £6,000 will have to be paid out of capital to cover the deficit of last year. The legacies, which for the ten years ended Dec. 31st, 1880, averaged nearly £6,000 a year, amounted in 1882 to £1,984. The committee have issued an appeal for increased support, to enable the benefits of the hospital—situated in one of the poorest and most populous neighbourhoods of London—to be extended.

Duelling among Students.

FORTUNATELY, the code of honour in this country has not yet reached that pitch of refinement when slight provocations or insults have to be combated with the sword or the pistol; or a word intended as a joke, to be settled in blood. Yet, duelling exists to a sed extent, and is even popular on the Continent, especially in some University towns of Germany. And, strange as it may seem, this debased and narrow-minded view of "honour" is encouraged by parents, who not unfrequently have to deplore the loss of a son in satisfaction of the miserable exigencies of a code. The University and city of Jena was, last week, in a terrible state of ferment on account of the number of encounters and the serious consequences ensuing therefrom. In one day no less than twenty-one duels were fought, and the weapons not having been previously cleaned poisoned the blood of those victims who were the recipients of thrusts or cuts. A correspondent states that about forty young fellows are now lying in hospital in a dangerous condition, some have already died, and it is not expected that more than half the number wounded will recover. In connection with this subject we may mention a remarkable infantile duel with stones, which took place in France a few days since, as illustrating the craze for duelling at a very early age. Two little boys Bardoux, *æt.* 11, and Morel, *æt.* 13, returning home from school, had a schoolboy's dispute; immediately they agreed to settle their differences with a duel, each chose his battery of stones, and when ready, the conflict commenced, ending with the death of the younger child from concussion caused by a blow in the head.

Death from Chloroform.

ONE of those cases which illustrate the fact that no care will ensure immunity from chloroform-death took place last week at Normanton. A drunken woman, in falling, dislocated her ankle and fractured the fibula, and, as she would not submit to have it reset without an anæsthetic, the surgeon in charge administered chloroform on an handkerchief. A few drops only had been inhaled when the patient died. The fatality was attributed to syncope consequent upon the drunken habits of the deceased. It is, however, the general experience that chronic alcoholism counteracts, rather than accentuates, the effects of chloroform, and the case seems to be one of those in which an idiosyncrasy existed. Against such condition no previous examination of the patient affords any safeguard.

Human Blood Pressure Curves.

AT the meeting of the Berlin Royal Society of Physicians on Feb. 16th, Professor Albert demonstrated some blood pressure curves obtained from men. They had been obtained from individuals about to undergo amputation of the leg. Previous to the commencement of the operation, the tibialis anticus was laid bare, and the canula inserted for about a minute. It was shown that the blood pressure immediately rose on raising up the individual (previously anæsthetised)—a contrary result to that obtained in Marey's experiments on animals.

The Provident System of Medical Relief.

THE scheme of medical relief for the working classes started under the auspices of Sir Charles Trevelyan, Mr. Stansfield, and others, has met with much success, and is gradually extending its operations throughout London. A public meeting was held at Dalston last week to discuss the advisability of forming a branch for this outlying district. The advantages of membership are apparent when it is stated that by the payment of a small fee per month good medical attendance and medicine are secured to the member who is unfortunate enough to require them. A small entrance fee is exacted, and members are not free to benefit for the first four weeks. Another advantage which will be duly appreciated by that large class who are so often the victims of doubtful medical treatment, is that they have here a choice of medical men from a staff which contains no unqualified assistants. Further, medical attendance at home is provided in cases of serious illness without extra charge; the drugs are stated to be of the best quality, and should a more than usually expensive medicine be needed it would be supplied. The management of each branch is vested in a committee elected by the members.

Progress in Medicine.

THE *Louisville Medical News* demonstrates the progress of medicine very clearly and pithily in the following interesting extract from its issue for February 10:—"And Asa, in the 39th year of his reign, was diseased in his feet until the disease was exceedingly great; yet in his disease he sought not the Lord, but the physicians. And Asa slept with his fathers."—2 Chronicles, xvi. Asa's foot trouble was probably erysipelas, since syphilis, guinea-worm, or gout in the feet would scarcely have killed him, and cancer of both feet is exceedingly rare. Asa's doctors were ignorant of quinine and tincture of iron, and without these remedies the treatment of erysipelas is, at least, unsatisfactory."

Leprosy in Norway.

THE well-known liability of the Norwegian people to leprosy has long been an important consideration in respect to the etiology of this disease. It is interesting therefore to learn that the number of persons so afflicted in Norway shows a large and steady decrease. From recently published returns this is made clear, for whereas in 1875, 2,008 leprosy patients were reported, the number had fallen at the end of 1880 to 1,582. How far the improvement is to be attributed to greater cleanliness of habit and increased care in preparation of the fish food largely indulged in, must be left for determination to those competent to speak on the subject. No doubt, however, these measures of regimen have been mainly instrumental in reducing the proportions of the disease among the Norwegian people.

DR. THOMPSON, who some time ago received a letter of thanks from the authorities at Viareggio for his medical services to the poor of that town, has recently been presented by the King of Greece with the Cross and Insignia of the Order of the Saviour.

Centenarians.

AN account has recently come from France of the death of a widow lady at the advanced age of 105 years; but even this great length of life has been exceeded by "Old Betty Lloyd," who was buried on Friday last at Garth, Ruabon, and who had attained no less an age than 107. This ancient dame is survived by two children, each more than 80 years old, and until within a fortnight of her death she preserved a very remarkable degree of activity. The aged Frenchwoman also is described as having been active and in possession of all her mental faculties until a few days before she died; indeed, so far as intelligence is concerned, she may be said to have preserved it to the last. In both these instances of longevity there would seem to be no doubt as to their reality, and they therefore possess a considerable degree of interest as proving the possible duration of life under conditions calculated to maintain health and vigour.

Premature Triumph.

OUR contemporary, the *Shield*, an organ "with an object," and that the repeal of the Contagious Diseases Acts, raises a shout of triumph in its latest issue, which, we venture to presume, is somewhat hastily indulged in. Our contemporary is apparently, by some means not accessible to less aspiring newspapers, in a position to prophecy what is in the womb of the immediate future, and, under the inspiring influence thus generated, it indulges in the following emphatic expressions of hopefulness:—"Our course is clear. We must maintain a perfectly steady and unbroken front under Parliamentary fire. If we do this—if we show ourselves worthy of the great cause which it is our privilege to champion—the triumph of that cause in the near future is as certain as the rising of to-morrow's sun."

M. COUTY, in a communication to the Academy of Sciences, shows that curare is not merely a paralyzing poison, but has in the first place a slightly convulsive action. It is also not only a peripheric poison, but to a certain degree affects the nervous centres.

WE understand that the Board of Trinity College has decided to confer the Obstetric Degree of the Dublin University (M.A.O.) on Dr. Kidd, of Dublin—*honoris causa*—and in recognition of his very distinguished services to the elucidation of that branch of medicine and surgery.

THE deaths of three members of the profession have occurred during the past few days at very advanced ages: Surgeon-Major John Wyer, of the Army Medical Service (retired), died at Whitechurch, Dorset, at 93; Dr. John Wilkinson, Senior Surgeon to the co. Limerick Infirmary, at 90; and Surgeon-Major Reid, of the Army Medical Service (retired), at Torquay, in his 86th year.

AT the annual collections in Manchester, in aid of the hospitals of that city last month, £4,635 5s. 8d. was contributed on the Sunday at the various places of worship, and £1,539 16s. 6d. on the Saturday as the working man's contributions. So far therefore the total contributions are £6,174 16s. 2d., the total at the corresponding period of last year being £6,226 18s. 7d.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE EXTRA-MURAL SCHOOL, EDINBURGH.—At an adjourned meeting of this School, held last week, it was decided to send a deputation to the Colleges to ask those august bodies to do "something" for the School. It may confidently be asserted that the deputation have not the slightest idea of the nature of the something that is to be done for them, and one thing is certain—nothing will be done. The School is given to these periodic and sudden fits of intense activity, so that nothing alarming need be feared in the present instance. The dinner to which a deputation of the Glasgow School were invited has been postponed *sine die*, simply, we believe, because when it came to the push so great was the cordiality between the different members of the School that the Dean of the Faculty found himself alone with his proposition to dine the Glasgow delegates. We await the result of the interview of the School deputation with the Colleges with some interest. If wise counsels prevail against university interest, the Colleges will again become—what one, at least, originally was—teaching bodies. As far as mere examinations go, the Government are quite capable to examine all candidates for licences to practise in the country, and therefore the *raison d'être* of the Colleges as mere examining bodies is a thing of the past. The anomaly of irresponsible bodies of men being empowered to grant licences to practise medicine and surgery must be removed.

OPEN SPACES IN EDINBURGH.—The future of the site of the old infirmary is still a subject of keen discussion, and rival suggestions are daily published in our Edinburgh contemporaries. In some of these the letting of the land for building purposes is proposed—in others, a garden or public square is suggested. Those who know the crowded state of the neighbourhood around the old infirmary would scarcely think twice before they gave their support to the latter proposal, but, unfortunately the question of cost comes in, and as it is the interest of the City Treasurer to show a good balance, regardless of the half-suffocated crowds of the Cowgate panting for more air and light, the infirmary site is likely to become a heap of stone and mortar. There is a health society in Edinburgh, presided over by the Earl of Rosebery, but beyond acting as a medium for a select few medical men to advertise their specialities, it might be dead and buried. Its vitality is exhibited in the winter by the delivery of the above advertisements, but its voice is never heard where any work of practical good is required. In London old graveyards are being turned into public gardens, but in Edinburgh open spaces in the most crowded parts of the city are conspicuous by their absence. We sincerely hope that wise counsels will prevail, and that the old infirmary site, perpetuated as a garden, may long maintain its old prestige as a health-restorer to the city.

PROFESSIONAL ADVERTISEMENTS.—We would draw the attention of the College of Physicians of London to the following, which we have cut from the advertising columns of our lay contemporary the *Scotsman*. The programme is certainly attractive to the general reader, and will enable any one troubled with congenital phimosis to find out where he may be circumcised by an improved method. The other articles will speak for themselves; but it seems scarcely fair that our professional brethren across the Tweed should enjoy such a monopoly of advertising themselves:—"The *Edinburgh Medical Journal* for March contains the following important original communications:—*Basilysis for Distocia*

from Hypertrophic Elongation of the Cervix Uteri, with illustrations, by Professor Alexander Russell Simpson; Germs and the Spray, by Mr. John Duncan, Surgeon to the Royal Infirmary, Edinburgh; Sequelæ of Tracheotomy occurring after Closure of Tracheal Wound, with an illustration, by J. Maxwell Ross, M.A., M.B., &c.; Case of Strangulated Congenital Inguinal Hernia, by Dr. Peter Hume Maclaren; On Dangerous Hæmorrhage from the External Genital Organs during and after Labour, by Dr. Peter Young; An Improved Method of Circumcision for Congenital Phimosis, by Dr. Neil Macleod; A Curious Instance of Cadaveric Spasm, by Dr. F. Ogston, Aberdeen; On the Treatment of Leprosy, by Surgeon-Major C. T. Peters, M.B.; Surgical Experiences in the Zulu and Transvaal Wars, by D. Blair Brown, F.R.C.S.E."

THE LECKIE-MACTIER FELLOWSHIP IN THE EDINBURGH UNIVERSITY has been awarded to Mr. George Armstrong Atkinson, M.B., C.M., after an examination in medicine, surgery, midwifery, medical jurisprudence, and public health, and written reports and commentaries on medical, surgical, and gynecological cases in the Royal Infirmary.

PROFESSOR GRAINGER STEWART.—Professor Grainger Stewart, who has so far recovered from the rheumatic attack from which he has been suffering all the winter as to enable him to travel, is now in the south of France. A letter was read last week from the Professor by Dr. James Ritchie, who has ably conducted the class during Dr. Stewart's absence, thanking the students for their regular attendance and consideration for him during his protracted illness. We sincerely hope that the Professor may soon return with renewed health, and we congratulate him and his class on having found so excellent a substitute in Dr. Ritchie.

ROYAL EDINBURGH ASYLUM FOR THE INSANE.—The statutory annual meeting of the Edinburgh Royal Asylum was held on the 26th ult., in the Council Chambers, the Lord Provost in the chair. Dr. Clouston read his annual report, as Physician-Superintendent, which stated that in the beginning of the year there were 822 patients, and on the 31st December there were 787. There were 329 admitted during the year, of whom 143 were men and 186 women. The total number of patients under treatment was 1,141. There were discharged during the year 281 patients, of whom 115 were men and 166 women. There were 83 deaths, of whom 47 were men and 36 women. The average number of patients resident during the year was 806—415 men and 391 women. The total number of admissions for the year (329) was 20 less than the average number for the past five years, and was lower than any year since 1875. An unusual number of the cases admitted this year were of a very acute character, or were accompanied by organic diseases of the brain, or by severe bodily disease. Sixteen died within the first month of residence, and 26 within the first three months, which far exceeded the average. The causes of the disease in the patients admitted were:—From domestic troubles, 44 persons, 41 of whom were women; business and money difficulties, 19 persons, 15 of whom were men; anxieties and worries, not domestic, 23 persons, 9 men and 14 women; religious and love difficulties played a small part in filling the asylum this year, 7 persons only having been put down to those causes; drink alone, 44 cases; accidents or injuries, 15; child-bearing, 16; the periods of puberty, the climacteric and old age, 39; and various bodily diseases and disorders, 68. There can be no doubt that as at present constituted there are only a small minority of the human race who can be made insane in the ordinary sense. By starvation, or poison, or fever, they can be made temporarily delirious, and their mental functions may be destroyed by organic brain disease; but true insanity

cannot be produced on them by any cause known to us. Some sort of direct or indirect predisposition is needed for this. One of the great problems—as yet unsolved—for medical men is how this predisposition to insanity can be avoided, and when present, how can it be got rid of. The preventive aspect of medicine in all its departments is perhaps the most hopeful of good to humanity; but as yet, remarked Dr. Clouston, they were unable to do very much in preventing the development of insanity with scientific certainty.

MR. WILLIAM McEWEN AND THE GLASGOW ROYAL INFIRMARY.—Considerable surprise will be very generally felt at the announcement that Mr. William McEwen has resigned from the directorate of the Glasgow Royal Infirmary. It is quite well known that for some time past the relations between the directors and the medical officers of the institution have been not a little strained. We are not in a position to say whether Mr. McEwen's resignation has any bearing on this question. For the long period of twenty years it must be said that Mr. McEwen has most faithfully and zealously served "the Royal," and no matter how erroneous his recent attitude towards the medical officers may be viewed by them, they will, we feel assured, be the first to admit that by his resignation the Infirmary sustains no mean loss. Besides being a director, Mr. McEwen was also chairman of the House Committee, having held that post since the year 1865. During his term of office Mr. McEwen attended no fewer than 1,270 ordinary meetings of the directors. He took a warm interest in the Royal Infirmary School, and making every allowance for difference of opinion on technical questions, we repeat, it will be difficult for the institution to secure in his place so zealous a friend.

ILLEGITIMACY IN SCOTLAND.—At the annual meeting of the Edinburgh Maternity Hospital, on the 1st inst., Lord Provost Harrison, who presided, took occasion to refer to the crying evil of illegitimacy, which mainly necessitated the existence of the institution of which he was president. He remarked that but for miserable ecclesiastical contentions the question would have been manfully faced long ere now. Scotland had as much need to wage warfare with it as with the vice of drunkenness. The scandal and sin of Scotland in that respect ought to make Scotland stink in the nostrils of the nations of the world. The vast mass of the respectable people of the country were totally insensible to, because ignorant of, it. But he knew too well the frightful amount of human misery which was annually caused in the land by the sin to which he referred. He did not so much blame the guilty parties as the conditions of society in which they were, and the low standard of public opinion which they had allowed to grow up in the society to which they belonged. There were many places in Ireland, even in the wildest districts, where the fall of a young woman from chastity was practically unknown for generations. It was a shameful thing they should have this sin so common in Bible-loving Scotland, when such an immunity from immorality existed in Catholic Ireland. The courting customs of Scotland must be attacked; and he would be a benefactor to his country who would head a crusade against customs which annually broke many hundreds of young and beautiful hearts, which ruined hundreds of young lives, and filled hundreds of households with grief. Meanwhile, in Scotland the rival religious bodies were too much occupied in fighting one another to attend to such a matter as this. It were well that these sensible reflections were taken seriously, and an authoritative effort made to stem that tide of national degeneracy which has long blanched the fair fame of Scotland.

PRESENTATION AT THE GLASGOW ROYAL INFIRMARY.—On the 24th ult. Miss Finlayson, of this institution, was presented with a handsome gold chain and locket, on the occasion of her leaving to fill the post of Matron of the Ayr Hospital. Mr. Clark, in making the presentation, referred briefly to the high qualities displayed by Miss Finlayson, adding that her success should act as an incentive to the other nurses to do their duties to the best of their ability. Dr. Thomas returned thanks on behalf of Miss Finlayson, and expressed regret at losing so good and faithful a servant.

HEALTH OF EDINBURGH.—The mortality of Edinburgh for the week ending with Saturday, the 24th ult., was 87, and the death-rate 20 per 1,000. Diseases of the chest accounted for 41 deaths, and zymotic causes for 5, of which 1 was due to diphtheria. No death was recorded from fever, scarlatina, or measles, the intimations of these diseases for the week being 8, 23, and 9.

MORTALITY IN GLASGOW.—For the week ending with Saturday, the 24th ult., the deaths in Glasgow were at the rate of 33 per 1,000 per annum, against 29 in the preceding week, and 25, 27, and 24 in the corresponding periods of 1882, 1881, and 1880.

WINDFALL FOR THE EDINBURGH ROYAL INFIRMARY.—By the will of the late Mr. Duncan Virtue, H.E.I.C.S., 3 Eaton Terrace, Edinburgh, the Edinburgh Royal Infirmary receives the residue of his estate after several legacies have been paid. The sum that will thus be received by the institution is estimated to amount to about £80,000. It is a condition of the bequest that the money will require to be capitalised, the interest being available as income.

Literary Notes and Gossip.

The Paris Academie des Sciences has awarded the "Prix Montyon" to Dr. Maillot, for his interesting works on the continued fevers of tropical and malarious countries.

PASTEUR's reply to Koch's defence appeared in *La Semaine Medicale*, of Jan. 25th. We hope shortly to give our readers an account of this further stage of the dispute between these two eminent explorers.

THE Briton Medical Life Association have sent us their "Life Almanac," which contains a considerable fund of useful information especially serviceable to medical practitioners in connection with assurances. The book likewise includes all the usual postal and general information of diaries, and will be found of much use.

THE *New York Medical Journal*, one of the most successful and best edited among the American medical monthlies, has this year become a weekly, and the *New York Medical Record* has increased its size superficially to nearly double that of the medical journals of this country; its proprietors are evidently bent upon a policy imitative of broadsides.

We are informed that for the the prize of 500 rupees offered by Surgeon-General Gordon, C.B., for the best essay on Fevers affecting British Soldiers in India, but one treatise was sent in, to which, though a careful production, the reward cannot be adjudged in consequence of non-compliance on the part of the writer with the conditions laid down by Dr. Gordon.

DR. ISAMBARD OWEN has reprinted the analysis of the results of treatment of acute rheumatism by different systems, which analysis formed the basis of his address to the Medical Society during the discussion on rheumatic fever in December, 1881. Those who were interested in that discussion and in our *résumé* of it at the time will be glad to have the opportunity of procuring Dr. Owen's tables and conclusions, which are published by Messrs. J. and A. Churchill.

THE *Deutsche Medicinal Zeitung* has the following in its "Vermischtes" column of Feb 15th:—"Signs and wonders still appear. The *Wiener Medicinischen Blätter*, No. 5/83, has had the honour of being confiscated on account of an article on Army Reform and Military Sanitation! And yet people talk of the scant consideration accorded to the profession of medicine!"

WE are asked to state by the Director of the Medical Department of Her Majesty's Local Government Board that in future, for the convenience of members of the medical profession desiring copies of the official reports made to the Board by their Medical Inspectors, these are now placed on sale. Thus the Government report of any outbreak of fever or contagious disorder can be had for a few pence as soon as it is issued from the press. The agents for the sale of these reports are Knight and Co., 90 Fleet Street; Shaw and Sons, Fetter Lane, London; and King and Co., King Street, Westminster.

MAYNE'S *Therapeutical Remembrancer* (Churchills), having reached a second edition, ought to have been more carefully corrected. On page 3 a line of capitals gives prominence to this: "Chalk (Calcis chloridum)," besides some other errors of a similar kind. There are also faults of style which must be disagreeable to many. It is amusing to read of errhines being "imbibed by the nose," and expectorants "facilitating ejection of mucus;" but we can guess what the author means, though the definition of emetics is so involved that some students may give up the riddle. Nevertheless, this little work will be convenient to many, and, being interleaved, will serve for memoranda on materia medica.

MR. T. PRIDGIN TEALE, F.R.C.S., has added to the claims he possesses to national gratitude by turning his attention to coal economisation. A lecture delivered by him at Leeds on this subject is now published with a view to the advice it contains being generally adopted. It gives instructions for, and numerous illustrations to assist, the expeditious transformation of ordinary fire-grates into slow-burning smokeless economisers of coal. We sincerely trust Mr. Teale may have reason to be satisfied with the success attending this effort of his to diminish the "soot and smoke throughout the kingdom, and so further one great aim of sanitary reformers—the improvement of the atmosphere of towns."

THE *Deutsche Medicinal Zeitung* announces that the second Congress for "Medicine" will be held at Wiesbaden from the 17th to the 20th of April next. Professor Frerichs will probably be President, as last year. The following subjects are already announced for discussion:—"On Tuberculosis: the influence of the discovery of the tubercle bacillus on the pathology, diagnosis, prognosis, and treatment of the disease." Rühle, of Bonn, Referent; Lichtheim, of Bern, Correferent. "Diphtheria: its parasitic nature, the relation of the local processes to the general infection, contagiousness, therapeutics (surgery), and prophylaxis." Ref., Gerhardt, of Würzburg; Corref., Klebs, of Zurich. "The Abortive Treatment of Infectious Diseases." Ref., Binz, of Bonn; Corref., Rossbach, of Jena.

As no essay of sufficient originality was sent in for the "Hammond Prize" of the American Neurological Association, this prize is again offered to universal competition on the following conditions:—1. The subject of the essay to be on the *Functions of the Thalamus in Man*; 2. The essays are to be based upon original observations and experiments on man and the lower animals, and may be written in the English, French, or German language; 3. Essays are to be sent to the Secretary of the Prize Committee, Dr. E. C. Seguin, 41 West 20th Street, New York City, on or before February 1, 1884; each essay to be marked by a distinctive device, or motto, and accompanied by a sealed envelope bearing the same device or motto, and containing the author's visiting card. The value of the prize is 500 dollars (about £100), to be presented in gold coin, or such other manner chosen by the successful essayist.

THE *Liverpool Medico-Chirurgical Journal*, a half-yearly publication, appeared for the fourth time in January last, a degree of success on which the editors will doubtless base still further efforts. The clinical portion of this number of

the *Journal* strikes us as stronger than the section devoted to reviews, and may be found ultimately to be more deserving of space and attention. Among the so-called "reviews" there is a curious critique on Mr. Reeve's "Human Morphology," extending over four pages, but which is almost entirely devoted to bemoaning the decadence of anatomical illustrations. The criticism of the work assumed to be under review is compressed into a few lines, and is of the most general description possible. We would really recommend a change in that part of the *Journal's* staff to which reviewing anatomical text-books is entrusted. Two cases, one of athetosis, and one of œdema glottidis, reported in the same part, are instructive and interesting.

THE Council of the International Congress of Hygiene, which is to meet at the Hague, Holland, in 1884, asks us to announce for competition a prize of 2,000 francs (£80 sterling), offered by the London Society for the Prevention of Blindness, to the author of the best essay, written in English, French, German, or Italian, on "The Causes of Blindness, and the Practical Means for Preventing it." Beside this prize, the International Society for the Improvement of the Condition of the Blind reserves to itself the right to award a second prize of 1,000 francs (£40 sterling), or two prizes of 500 francs (£20 sterling) each, and a silver-gilt medal, with a diploma, should it see fit, to such other essays as should, in the opinion of the International jury, be deserving of it. Essays are to be sent to the Secretary (Dr. Hattenhoff, Geneva) not later than the 31st of March, 1884. Every manuscript has to be distinguished by a motto, which is also to be written on a sealed envelope containing the name, Christian name, titles, and address of the author.

THERE was recently found in the library of the Faculty of Physicians and Surgeons, Glasgow, a set of manuscript notes of lectures on surgery by John Hunter. These notes, which we have had the privilege of personally inspecting, are written in a good hand, are in a fair state of preservation, belong evidently to an early period, and seem carefully reported, even to the ornamental expletives which custom one hundred years ago permitted. Many of the observations are interesting. What would Hunter have said to antiseptic surgery had it been foreshadowed in his time when he thus expresses himself: "It is not *external air* which causes suppuration; the part would in time suppurate *in vacuo*." The breast-bone and wing-bone of birds communicate with the air cells of their lungs, and yet suppuration does not arise there without a stimulus of imperfection is given." Not a few old-fashioned medical men of the present day are still disposed to *err* with Hunter.

MANY of Hunter's remarks on venereal disease contained in these notes are interesting. We notice a singular contradiction—"But clap is merely a local disease, and I cannot conceive that a clap can ever become a pox." In another it is remarked—"In every clap, especially one of long standing, and one that has been treated by purging, I think it possible for some of the matter to be absorbed, which may accordingly produce a pox." A difficulty which presents to the present generation of medical men no less than to Hunter is thus got over: "I have known a woman clap different men for years, herself having no symptom of it; so that the woman may have the disease without knowing it, or the parts may have become so habituated to it that it does not at all affect herself. . . . A woman may give a clap without having one, for a clapped penis may enter the vagina and leave matter, which a sound penis coming after may take up, and if any remains it may be washed away by urine, and thus the woman may escape the disease." There are many very interesting observations in these notes, and in the light of them we are not at all certain that in some respects the *science* of medicine has not rather retrograded than advanced.

THE principle that "birds of a feather" exercises an influence with the profession is very strongly evidenced in regard to choice of habitations. In every large town, a street or square will generally be found as the favourite *locale* of medical men. A writer in the March number of *Old and New London* speaks of this by special reference to eminent members of the profession in London of the past and present who have lived or are living in Brook Street. He says: "This street has for a century been the residence of successful surgeons

and physicians. Hither Sir Charles Bell, in the height of his fame, removed about the year 1831, and here he lived till his final settlement in Edinburgh in 1835. Sir Henry Holland, the fashionable Court physician, resided for upwards of fifty years at No. 25, formerly the residence of Edmund Burke. His house was a centre of literary and scientific society, and around his table often were gathered the Macaulays, the Wilberforces, and Sydney Smith. He attended the deathbeds of no less than five Premiers, and of several members of our own and some other royal houses. He was the physician to the Princess Charlotte, and at a later date to Her Majesty and the late Prince Consort." Her Majesty's Physician in Ordinary, Sir William Jenner, and her Physician Extraordinary, Sir William Gull, are also residents in Brook Street at the present time, together with twenty-seven other members of the profession of more or less eminence.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, Jan. 31st:—The Student's Handbook of Surgical Anatomy, by John McLachlan. The Treatment of Acute Rheumatism, by Isambard Owen, M.D. Clinical Lectures on the Diseases of Women, by J. Matthews Duncan, M.D. Micro-Photography, by A. C. Malley, M.B. Hahnemann, the Founder of Scientific Therapeutics, by R. E. Dudgeon, M.D. What is Religion? by Robert Lewins, M.D. Insanity: its Cause, Prevention, and Treatment, by W. Harris, M.R.C.P. The Administration of the Dental Act, by J. Tomes, F.R.S. The Principal Southern and Swiss Health Resorts, by William Marcet, M.D., F.R.S. Economy of Coal in House Fires, by T. Pridgin Teale, F.R.C.S. Poverty, Taxation, and their Remedy, by Thos. Briggs. Compulsory Notification of Infectious Diseases Considered, by R. Hamilton, F.R.C.S. Refraction of the Eye, by A. S. Morton, M.B. Syllabus of Materia Medica, by Drs. Harvey and Davidson. Tapeworms, by T. Spencer Cobbold, M.D. Official Report of the Smoke Abatement Committee, 1882. Transactions of the Liverpool Medical Institution. Journal of Psychological Medicine. Eleventh Annual Report of the Local Government Board. St. Bartholomew's Hospital Reports, Vol. XVIII.

Correspondence.

OVARIOTOMY STATISTICS.

We have been requested to publish the following letter from Mr. Spencer Wells to Professor Gross:—

3 Upper Grosvenor Street, London,
February 27, 1883.

My dear Professor Gross,—You have published in the *Philadelphia Medical News* a statement comparing the results of my operations of ovariectomy in 1,088 cases with those of three other operators in 381, 328, and 228 cases respectively, making a total of 985 cases. The mortality of my cases is given correctly at 22·15 per cent., and that of the other operators as 10·76, 10·67, and 11·94 per cent. On this plain statement, as you have published it, any one would conclude that I am a less successful operator than my juniors. Indeed, the author of a very eulogistic review of my last book in the *American Journal of Medical Sciences* of January, 1883, misled by a false statement in the *American Journal of Obstetrics* (vol. xv., page 547), that I "had gone on for twenty years operating on hundreds of cases with a mortality of 25 per cent.," takes the trouble to give what he believes to be a true explanation of the "high range of mortality in his [my] ovariectomies." He says that I had laboured for an "ideal success," but "his [my] own practice fell short of this ideal." If it were true that after twenty years' operating I had gone on operating with a mortality of 25 per cent., while others did not exceed 10 or 12, some such explanations as those proffered by my able and kindly reviewer might serve as my excuse. But it is not true. When I had been operating for twenty years I had reduced my mortality to 11·62 per cent. The results of successive series of 100 cases had been made known— from 34 in the first, and 28 in the second, to 17 in the ninth, and 11 in the tenth series of 100 cases. My cases of 1879, 1880, and 1881 had been published, with results of 11·62, 9·57, and 10·7 per cent.; and in the preface to my book, published in May, 1882, I afford proof that, "notwithstand-

ing the fact of my being often called upon to treat patients rejected by other surgeons as unfavourable cases, the progressive diminution of the mortality still continues." I added, "It is still more gratifying to be able to add that this increasing success is not confined to myself nor to British surgeons, but is also established in Germany, France, and Italy." There really can be no excuse for this attempt to discredit me with a high mortality after twenty years' experience, as in my book (pages 214-15) I had shown very plainly how in successive periods of five years the mortality progressively diminished, and that in the

First five years	about 1 in 3 died.
Second and third five years...	" 1 in 4 "
Fourth five years	" 1 in 5 "
Last two years	" 1 in 10 "

Or, putting it in another form, that in the

First five years	70 per cent. recovered.
Second five years	74 " "
Third five years	73 " "
Fourth five years	80 " "
Two last years	90 " "

I trust, my dear Professor, that you will accept my desire to stand well with my American brethren as a sufficient excuse for this long letter. And, with sincere respect,

I am, &c.,
T. SPENCER WELLS.

THE BUMBLEDOM OF THE COLLEGE OF PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—The bumbledom of the College of Physicians is too intolerable to be passed over in silence, as day after day advertisement is followed by advertisement of some favoured Fellow in the daily press. Repeated advertisement of medical lectures in the lay press is indefensible on any grounds. Certainly the practice cannot be defended on the plea of expediency, for the profession is more effectually reached through the columns of the medical journals, and only in extreme instances can the public be expected to take the smallest interest in lectures on Sterility or Phthisis, scarcely more in Harveian orations. What excuse, then, can the President and Censors of the College offer for the continuance of the very questionable puff-direct of their Fellows? There is yet another form of advertisement not less objectionable because it is somewhat more fashionable. This may be described as the bulletin advertisement nuisance, and which the bumbledom of the College would do well to keep within proper bounds, since it is much abused, and is consequently fraught with danger to the honour of the Fellows. This form of advertising was at one time confined to its more legitimate purpose of allaying alarm when the head of the State was attacked by illness, but now it is made the stalking-horse of every one who can afford to call in the eminent Dr. Snooks, F.R.C.P., who, together with a string of smaller luminaries in attendance upon Mr. Jones, M.P., make a point of issuing a daily bulletin of the state of their illustrious patients. Even the President of the College, I observe, is not proof against this form of puff-direct, and which, under any circumstances, can only be said to be a bolder and more daring kind of advertisement.

I am, &c.,
ANOTHER MEMBER OF THE COLLEGE.

March 3rd, 1883.

Obituary.

SURGEON WYER, M.R.C.S. (Army Medical Service).

THE death of Surgeon John Wyer, of Whitechurch, Canonicoorum, Dorset, is announced, at the great age of 94. Mr. Wyer entered the Army Medical Department as hospital assistant in the early part of 1811, and, it is said, was the oldest medical officer in the Department. He served in the Peninsula on staff, and with the 88th Regiment from 1811 to the end of the war in 1814, and received the medal with five clasps for Vittoria, Pyrenees, Niville, Orthez, and Toulouse. Surgeon Wyer also served in Canada, and was present at the taking of Platsberg, at the Cape of Good Hope, and at the West Indies. A few years back Her Majesty conferred on him a pension of £100 per annum for distinguished and meritorious service.

GEORGE MACKENZIE BACON, M.D.

IN sad contrast in point of age to the veteran above referred to is our announcement of the death, at the early age of 47, of Dr. Bacon, Medical Superintendent of the Cambridge Lunatic Asylum, which occurred after three days' illness of colic. Deceased, who was highly esteemed by a wide circle of professional and other friends, was a native of Lewes, Sussex, his father being the proprietor of that venerable publication the *Sussex Advertiser*. He received his earlier education at the Lewes Grammar School, and afterwards became a pupil of the late Mr. W. H. Murrell, surgeon, of Lewes, with whom he remained four years. He then took up as a specialty the study of psychological medicine, in which he soon attained distinction. After leaving Lewes Mr. Bacon entered Guy's Hospital, and in 1858 obtained the diplomas of L.S.A., L.M., and M.R.C.S. In 1862 the University of St. Andrews conferred upon him the degree of M.D., and the University of Cambridge in 1877 gave him an honorary degree of M.A., in recognition of his general merit, and more particularly in acknowledgment of the valuable services rendered to the University by gratuitous lectures addressed to undergraduates at the asylum since 1869—lectures, we may add, which have been continued to the present year. Dr. Bacon was for some time Assistant Medical Officer to the Norfolk County Lunatic Asylum, and in 1867 obtained the appointment of Resident Medical Superintendent at the County Lunatic Asylum at Fulbourn, Cambridge. This appointment he was holding when death so suddenly deprived the profession of one of its most sterling members, the asylum of its honoured head, and a wide circle of friends of one whom it will long mourn.

PASS LISTS.

University of Cambridge.—At a Congregation held on March 1st, the following medical degrees were conferred:—

Bachelor of Medicine.

Bullar, John Follett, Trinity. | Knowling, Ernest M., King's.
Swift, Harry, Caius College.

Royal College of Physicians of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.—The following candidates have passed the final examination for the double qualification:—

Cable, John, Glasgow. | Muir, James, Glasgow.
Gray, Charles Alex., Glasgow. | Shaw, Peter Fleming, Glasgow.
Johnson, Samuel, Edinburgh.

Army Medical Service.—The following is a list of candidates who were successful for appointments as surgeons in Her Majesty's British Medical Service at the Competitive Examination in London on February 19th and following days, in order of merit:—

	Marks.		Marks.
Bruce, D.	2680	Moore, R. R. H. ..	2320
Gordon, H. C. ..	2460	O'Shaughnessy, P.	
Bell, H. L.	2447	J. B.	2170
Riordan, J.	2435	Robertson, J. R. S.	2170
Dehom, H. A. ..	2415	Tate, A. E.	2130
Firth, R. H.	2400	Faunce, C. E.	2130
Nells, G.	2350	Leudrum, W. H. ..	2090
Galloway, P. J. ..	2280	Wyatt, H. J.	2050

Navy Medical Department.—The following is a list of the successful candidates for appointment as surgeons in the Royal Navy at the Competitive Examination in London on 19th February and following days, in the order of merit:—

	Marks.		Marks.
Mends, B. S.	2600	Penn, J. E.	2100
Crowley, T. J. ..	2445	Nicholson, R. H. ..	2060
Keese, A.	2415	Bury P. B.	1990
Lennox, D.	2350	Seymour, J. N. ..	1975
Gunn, B. C. E. F.	2185	Barrington, J. L. ..	1825
Hoskyn, D. T. ..	2150	Suggs, J.	1875

Indian Medical Service.—List of candidates for Her Majesty's Indian Medical Service who were successful at the Competitive Examination held at Burlington House on February 19 and following days. Twenty-two candidates competed for five appointments; twenty-one were reported qualified:—

	Marks.		Marks.
Young, J. M.	2555	Quicke, W. H.	2355
Jamieson, G.	2525	Evana, A. O.	2225
Collie, M. A. T. ..	2515		

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

POOR-LAW SERVICE.—W. H. & M. O. asks: What is my position in regard to visiting when requested by the relieving officer to attend patients not in my own district? Have I not a claim for payment by the Board of Guardians? A few weeks ago a red line was left at my house (unaccompanied by any message from the doctor of the district, who simply told the bearer to procure the ticket, and that "I was bound to go"), and not being able to go myself, I sent a medical friend in my place, sending my own horse and car with him, and promising him the fee which I believed I should be entitled to from the Board, to whom I sent in my application. I have had no reply whatever from the Board, but I have heard indirectly that my claim would not be entertained, and because the medical officer of the district in question had written to the clerk of union offering to settle—not with me—but with the gentleman who kindly took in my place the duty which was imposed on me by the ticket of the relieving officer.

[If it pleases our correspondent to oblige a neighbouring practitioner he may attend, outside his own district, on a request to do so; but he is under no obligation whatever to do so; and a relieving officer shows gross ignorance of his duty if he issues a ticket except to the officer of the district in which the patient resides—such ticket is waste paper. If the relieving officer engages the services of a medical practitioner, the Board of Guardians is distinctly liable to pay for the services rendered. If our correspondent wishes to test the matter he should pay the practitioner whom he employed to see the case, and should then require the Guardians—as a matter of simple contract—to pay for the services which the relieving officer engaged. He can recover the fee at law if he takes this course—presuming that the facts are as he states them.—ED.]

DR. GROSS.—Such information as we possess on the subject has been communicated to us at different times by the immediate authors of the experiment, who therefore must be considered responsible for all the statements hitherto made. Any corrections you are able to make shall receive careful attention.

A. A. T.—There is no remedy open to you under the circumstances. You can summon the responsible parties in a county court, and for this privilege, the only one you enjoy in return for your registration fee, the Council is entitled to all the credit you are disposed to give it.

INARTICULATE.—An "elastic" ligament is so decided a novelty that we would strongly advise your pursuing further investigations, and *studies*, before publishing your views more widely, as you express the intention of doing.

A CORRESPONDENT asks: If a medical officer who holds two appointments (viz., a workhouse and dispensary district in the same union) can present himself for a third appointment and be elected thereto without resigning either of the above?

[He may hold a dozen such appointments if the Local Government Board sanctions his doing so. Whether they will do so or not depends chiefly upon his capacity to fulfil the plurality of duties.—ED.]

LONGEVITY—REMARKABLE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—A few hours before reading the "Remarkable Case of Longevity in Scotland" furnished by your Northern Correspondent, Feb. 28th, I had seen in *La Presse* of Tuesday, Feb. 27th, a still more extraordinary case, of which, on account of its unique character, I send herewith a brief résumé for insertion in the *Medical Press*, as it will doubtless interest many of your readers:—

The case is that of a Russian peasant, named James Zygolof, who had just died at Odessa, at the age of 147. Of the rest of the family, his son is still alive, at the age of 115 years, his grandson at 85 years, and his great grand-son at 40 years.

More wonderful still, Zygolof never smoked nor drank any alcoholic liquors in his time. And the history ends by saying that this is a *good point for the temperance societies*; and as I give my endorsement to that, I now wish to afford you, Sir, the opportunity of making the fact known to your numerous readers, through whom I trust that Sir Wilfrid Lawson, M.P., and Cardinal Manning may get to know the story, and in turn cheer their disciples with the knowledge.

I am, Sir, yours sincerely,

JAMES O'FLANAGAN.

Houghton-le-Spring, Durham,
March 5th, 1883.

M. R. C. S. P. (Devonport).—The individual referred to as having falsely assumed and practised under the name of the gentleman in question bolted as soon as a warrant was issued; we hear, however, that he has just been arrested, and will probably be brought before a magistrate this week.

DR. FRANCIS.—Thanks for the notes, which are interesting, and shall appear in an early number.

A STUDENT (Manchester) is referred to the announcement of the Royal College of Surgeons in our last issue for an answer to his inquiry. He will there see that Students completing their Anatomical Studies at the end of the present Winter Session, and who desire to present themselves for the Examination commencing on Friday the 30th of March, must forward the required Certificates through the post not later than Thursday, 22nd March; and for the Examination commencing on Friday the 20th of April, Students must send through the post their applications, accompanied by their Certificates, not later than Friday the 6th of April.

A THIRD YEAR'S MAN.—The book is a most reliable one; you cannot do better.

DR. B. (Liverpool).—Thanks; it shall appear in an early impression.

A. F.—We cannot permit the insertion of any letter that reflects unjustly on the actions of an individual member of the profession.

MEETINGS OF THE SOCIETIES.

WEDNESDAY, MARCH 7TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m., Professor Flower, On the Anatomy of the Horse and its Allies.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m., Croonian Lecture: Dr. J. E. Pollock, On Modern Theories and Treatment of Phthisis.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 p.m., Surgeon-General John Murray, On the Delhi or Oriental Sore.—Deputy Surgeon-General Joseph Ewart, On the Causes of the Excessive Mortality among the Women and Children of the European Army of India.

OBSTETRICAL SOCIETY OF LONDON.—8 p.m., Specimens will be shown.—Inaugural Address by the President, Dr. Gervis.—Dr. Godson, On Cases of Clinical Interest.

THURSDAY, MARCH 8TH.

ROYAL INSTITUTION.—3 p.m., Professor Dewar, On the Spectroscopy and its Applications.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 30 p.m., Dr. C. E. Fitzgerald, On the Connection between Uterine and Eye Diseases.—Mr. Adams Frost, On Pulsating Exophthalmos.—Dr. David Little, On Sarcoma of Iris successfully removed.—Mr. A. H. Benson, On Farsia of Ocular Muscles after Diptheria.—8 p.m., Living and Card Specimens.—Mr. J. E. Adams, On Embolism of both Retinal Arteries.—Mr. A. H. Benson, On Ophthalmoscopic Drawings.—Mr. Adams Frost, On Double Pulsating Exophthalmos.

FRIDAY, MARCH 9TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m., Professor Flower, On the Anatomy of the Horse and its Allies.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m., Lumleian Lecture: Dr. A. B. Garrod, On Uric Acid, in its relation to Renal Calculi and Gravel.

ROYAL INSTITUTION.—8 p.m., Professor G. D. Living, On the Ultra-violet Spectra of the Elements.

CLINICAL SOCIETY OF LONDON.—Mr. Godlee, On a Case of Fracture of the Radius and Dislocation forwards of the Ulna at the Wrist, in which the lower end of the latter bone was removed to effect reduction.—Dr. Pearson and Dr. Broadbent, On a Case of Acute Necrosis of the Right Orbital Plate of the Frontal Bone, giving rise to Thrombosis in the frontal end of the Longitudinal Sinus, in the Cavernous Sinus, and Ophthalmic Vein.—Dr. G. Johnson, On Picric Acid as a Test for Albumen and Sugar in the Urine.—Mr. E. W. Parker, On a Contused Wound of the Thigh and Leg in a Young Child; gangrene of the limb; death.—Dr. Dyce Duckworth will exhibit (1) a Case of Remarkable Hardness of the Ears; (2) a Case of Rheumatoidal Subcutaneous Nodules.—Dr. S. Mackenzie will show a Case of Subcutaneous Nodules without definite Rheumatism.

ACADEMY OF MEDICINE IN IRELAND.—Surgical Section.—Living Specimens: Mr. Swan, A Case of Funicolitis treated by open operation on Contracted Tissues.—Specimens exhibited by Card: Mr. Hayes—1. Morbid Structures removed in Excision of the Knee; 2. Adenoid Tumour removed from the Digestive Region; 3. Secondary Carcinoma involving the Body of the Lower Jaw.—Mr. Wheeler—1. Large Fungulous Tumour situated close to Left Anterior Superior Spine of Ilium; 2. Index Finger removed for Melanotic Cancer; 3. Cast of Compound Dislocation of Ankle Joint; 4. Cast of Stump after Amputation for above; 5. Cast and Drawing, showing Epithelioma of Sole of Foot.—Mr. Stokes—1. Drawing illustrating a Cast of a large Pessile Fistula; 2. Drawing of same case after a series of plastic operations.—Mr. Thomson, Vesical Calculi.—Papers: Mr. Kendall Franks, Spontaneous Dislocation.—Dr. M'Donnell, Injuries of the Spine followed by progressive Muscular Atrophy.—The President, Excision of the Hip.

Births.

FINNY.—Feb. 19th, at 19 Lower Baggot Street, Dublin, the wife of J. Magee Finny, M.D., of a daughter.

WOODS.—Feb. 18th, at Killarney, the wife of Oscar T. Woods, M.D., of a daughter.

Deaths.

CHRISTOPHERS.—Feb. 26th, at Westgate Terrace, South Kensington, John Crown Christophers, F.R.C.S., aged 70.

DALY.—Feb. 24th, at the residence of his brother, Stratford Road, Manchester, F. Herbert Daly, L.R.C.P. Ed., aged 24.

REID.—Feb. 24th, at Ashbury Dale, Torquay, James Reid, Surgeon-Major (retired), Her Majesty's Madras Army, aged 85.

SIGSTON.—Feb. 20th, Joseph Teale Sigston, Surgeon, of Welburn, formerly of Leeds, aged 76.

UTTING.—Feb. 19th, at his residence, White Ladies' Road, Clifton, George Utting, M.R.C.S., aged 85.

WYER.—Feb. 23rd, at Whitechurch, Canonlorum, Dorset, Surgeon John Wyer, A.M.D. (retired), aged 93.

Clinical Lecture

ON

HERNIA CEREBRI AND THE COMPARISON BETWEEN MENINGITIS AND CEREBRITIS.

Delivered at St. Mary's Hospital,

By ARTHUR TREHERN NORTON.

R. W., a little girl, about twelve years of age, on the 21st March, 1882, was struck on the head by a notice board, which was blown from its attachment by the recent gale. When seen in the waiting-room she was walking about apparently not much the worse for the injury she had sustained. On examination of the wound I found a small puncture about the middle of the left parietal bone, into which blood welled up and returned at each pulsation. I could not detect a fracture by the finger, but the swelling up of the blood could only take place as a result of the pulsation of the brain, and therefore it was evident that not only was there a fracture of the skull, but that there was displacement of bone sufficient to allow of the brain pulsation affecting the blood external to the bone. With the probe I detected that a piece of bone had been driven down about a quarter of an inch below its proper level. I therefore at once trephined and took away some four or five irregular-shaped pieces of bone which were depressed, and which had all of them both torn the dura mater and lacerated the brain. A pad of lint dipped in carbolic oil was laid on the dura mater, and the flaps drawn together sufficiently to permit of free drainage from the wound. Ice-bags were ordered to the head, and iced milk her only diet.

On the 22nd she had slept well, but was sick in the morning. A small pulse of 108, and temperature 99.4°. On the 23rd the temperature rose to 100° in the morning, and 102° in the evening. The tongue was white and the face flushed, but the wound looked well, and there was no discharge. She was perfectly sensible, and complained of no pain in the head, but sickness was continuous all day. To overcome inflammation of the membranes, which was evidently supervening, and

to allay the sickness, which was exhausting, the following was ordered:—

Vin. ant., G. T., ℥xxx.;
Tr. opii, ℥vj.;
Sp. chlorof., ℥x.;
Aquæ. ad., ℥ss. Every four hours.

The bowels not having been opened castor oil had been given, but immediately vomited. The tasteless ol ricini was therefore ordered iced, and, in teaspoonful doses, this she retained. On the night of 23rd she slept well, and the vomiting ceased after taking the antimonial mixture, but during the night the temperature rose to 103.6°. On the following morning, the 24th March, cerebral protrusion had taken place at the wound. The temperature rose to 105.4°; tongue white; pulse 120. She became restless; did not know her mother; scratched at things with her right hand. To lower the temperature a mixture of Tr. acetonit., ℥ij., and Tr. verat. virides, ℥v., was ordered every four hours. The temperature fell to 99°, and the mixture was omitted; but towards night rose again to 104°. The veratrum mixture was continued, and it gradually fell to 102°. All sickness had ceased.

On the 25th March respirations 16 in the minute; pulse 104, regular, but very weak; and temperature fallen to 102. The medicine was discontinued. She had full use of all muscles; no part paralysed. At one o'clock, p.m., the temperature rose to 104.8°. She was put into a bath of 98° gradually cooled to 85°. After fourteen minutes' immersion her temperature was 100°, but in five minutes after leaving the bath it had returned to 103.6°, showing that her skin only had cooled by contact with water of a lower temperature. She was quite conscious, and asked often for milk. At 3.30 she had a convulsion lasting four minutes; right side of face rapidly and violently twitched, and the right side of body in a quiver. She appeared to be asleep during the convulsion. The urine on examination was found to contain some albumen. Towards evening the left side of the face, left arm, and leg were paralysed.

On the 26th she had passed a restless night, but was

quite conscious; asked for milk, and stated she wished to use the bed-pan. The pulse was 98, regular, and good strength; and the temperature 102° . There was fair movement in the left leg, though plantar reflex almost annulled. Left side of face and left arm were still paralysed. No further convulsions. She seemed decidedly improved, but she had vomited three times.

On the 27th there was a change for the worse. Pulse 125, and temp. 104.2° . Had been restless throughout the night, keeping the whole ward awake. In the early morning she had a convulsion lasting twenty minutes; facial twitching continually on the right side. It was carefully observed that her tongue always pointed to the right, though the left side of her face was quite paralysed, the mouth being drawn to the right. Was continually sick. Passed her water in bed. Respirations 19. Hectic on each cheek. Hernia cerebri increasing in size.

March 28th.—Urine dribbling away, or rather being continually passed involuntarily—though bladder not loaded. From 5 to 8 a.m. a continuous series of general convulsions. Pulse 140. Half-conscious state. Does not know her parents. Towards evening pulse 164. She could move the left arm a little, though she had not been able to do so for some days. There was also sensation in left arm. She was ordered four grains of quinine every six hours. Brandy was being given— ʒiv. —in the day. The temperature fell to 99.8° .

On the 29th the condition was much the same as on the previous day, but the temperature gradually rose through the day to 104.8° .

On the 30th sick several times. Took any nourishment greedily. Knew nobody. Pupils widely dilated. Pulse 190, irregular. The quinine had no effect in lowering the temperature, which hovered about 104° . At 5 p.m. breathing became laboured. There had been no convulsions for two days. She became rapidly weaker, and died at 2 a.m. on the 31st.

The cause of death, and the signs and symptoms throughout, were those of meningitis.

The post-mortem notes are as follows:—On reflecting scalp there is hæmorrhage beneath epicranial tendon in right parietal region, and near squamo-parietal suture the pericranium is separated from the bone over a small area. Through an opening in the pericranium some sanious pus exudes. The trephine wound is situated 1" from sagittal suture, and its edge in front touches the coronal suture. Through the opening a brownish red mass of granulation tissue protrudes and overlaps the edges. From the aperture a fissure runs backwards through the right parietal eminence, and ends at the parieto-occipital suture. Near the parietal eminence another fissure passes from the first downwards and forwards to end about $1\frac{1}{4}$ " the mastoid process. On pressure pus escapes through the fissures in the bone. In the neighbourhood of the injury there is a layer of pus between the dura mater and the bone, and also beneath the dura mater. There is diffuse reddish injection of the vessels of the pia mater, and the large veins are filled up with blood. Scattered collections of yellowish lymph are seen on the sulci on right side of brain, more especially about posterior limb of Sylvian fissure. On examining base of brain a thick layer of yellowish green lymph surrounds the nerves, and extends from the olfactory sulci in front, to the pons and medulla behind. On section the red points are more numerous than natural, and the grey substance has a distinct reddish tinge. The lateral ventricles contain slight excess of fluid; choroid plexus and vessels of velum filled with blood. Pons, medulla, and basal ganglia reddened—otherwise apparently healthy. Basal sinuses filled with black clots. On examining bones the anterior fissure mentioned above ends by turning inwards and backwards to the superior border of petrous bone, about $\frac{1}{2}$ " from its base.

For comparison I will give you the notes of another

case of fracture of the skull, with hernia cerebri, recently in the hospital.

S. G., was struck on head by a metal pail full of mortar.

On admission.—Cut five inches long along right occipital and parietal bones. About the middle of wound bone was seen, and a slightly depressed fracture about size of a shilling made out. Blood seen to rise and fall with respiration through small hole in bone. Man quite conscious. Could sit up, walk, and talk. Pupils equal. Drainage tube laid in wound, and edges brought together with silver sutures. Calomel, gr. x., and ol. ricini.

June 20th.—Restless, but slept off and on. Temp. 103° . Bowels not open. Passed no urine. Was sick. Water drawn off and mist. alba, ʒij . Ice-bag to head. Was bled to ʒij .

22nd.—Temp. 104° . Bled again. Four leeches to head.

24th.—11 30 a.m. Temp. 102.6° . Drowsy and delirious for last twenty-four hours. Has had several convulsive seizures, consisting of clonic spasm, lasting from one to three minutes. No divergence of tongue. Pupils dilated, but nearly even (left perhaps rather more than right). Considerable loss of power in left hand and arm, but not complete paralysis. Can move both legs. Intense pain in frontal region and under seat of wound. Fragments of bone were elevated and removed, and some brain substance came through wound. Dura mater infused, and a small strip in a sloughing state was removed. Considerable bleeding.

June 25th.—Large quantity of pus found underneath lower flap, and counter opening made and drainage-tube put in. Quite sensible. Temp. 100.6° .

26th.—Conscious and delirious by turns in night. Convulsive seizure for three minutes. Right arm, shoulder, and leg drawn violently up and down. Temperature ranging 100.6° and 101.2° . A second slight seizure; face only affected. In morning quite conscious, and says he feels much better. Not so much pain. Respirations 30. Pulse 66, full and soft. Pupils normal and equal. No divergence of tongue. Good power and sensation on both sides of body. Power of grasping impaired in both hands. No double vision. Speech intact. Can feed himself. Dura mater looking rather dark. Ice-bag continued.

27th.—Temp. 102° in the morning, 100° in the evening. Quite conscious in night, and no delirium. No pain. Weaker. Two slight facial convulsions, lasting about a minute; also another in which right arm and shoulder were slightly affected. This morning looks less pinched. Pulse 66, of fair volume and strength. More power in left hand, but weaker than right. Iced milk taken freely.

28th.—In night highest temp. 100.4° . Slightly delirious. Took food well. In morning looks quite bright and rational. Much less pain in head. Talks freely.

29th.—Enema. Wound poulticed. Fair night. Wound healthy.

30th.—Quiet night. Bowels opened. Food taken well. Looks better. Speaks quicker. Complains of right frontal headache. Left hand much stronger, but still weaker than right. No photophobia. Temp., morning, 99° ; evening, 100.6° .

July 2nd.—Best night he has had. Temp. 100.4° . No pain in head. Skin hot and dry. Round mass appearing in wound.

3rd.—Temp. 100.6° . On this day he was attacked with rigors, and more drowsy. No signs of paralysis, save that left eye half open when asleep; but movement, sensation, and consciousness are unimpaired. Water passed continually into bed. Protrusion increased in size, pulsates, and smells badly.

4th.—More drowsy. Answers mechanically, and not always correctly as to facts. Mass in wound larger; still poulticed. Temp. 100° .

5th.—Restless night. Temp. 99.4°.

6th.—Not conscious. Not taking food so well.

8th.—Very delirious, pulled off bandages, and crushes the protruding mass. Mass quite soft and rotten, and easily brushed away with finger. Very drowsy in morning, and takes food worse. Will not put out tongue. Pupils equal. Can move limbs, but does so slowly. Temp. 100°.

11th.—Gradually been getting worse. Scarcely conscious, and continually muttering and fidgeting. Temp. yesterday, 3 p.m., 100.3°; 7 p.m., normal; this morning, 99.3°.

12th.—More restless. Frontal pain. Pupils react to light, but are more dilated. Urine contains mucus; does not smell.

15th.—Much same condition since 12th. Only semi-conscious, and answers questions slowly and indistinctly. Face slightly drawn to right, and left eye partially open. Pupils equal, but more dilated. Tongue appears to point to left. Skin cold and dry. Pulse 106, small, and not strong. Is constantly fidgeting about with his hands and moving his legs. Sometimes passes water involuntarily.

16th.—Looks a little less pinched, but has lost much flesh.

17th.—Eyes closed and very sunken. Seems unconscious, but always fidgeting. Pulse 120, small and feeble. Temp. 99°.

18th.—Left face quite paralysed, Pulse 138.

19th.—Looks very worn. Pulse 150. Temp. 101.4°.

20th.—From 7 p.m. to 10 p.m. very quiet; then continual facial and general twitching till 2 a.m. After this he became quieter, and died shortly after.

The cause of death in this case was not meningitis, but abscess, with destruction of the brain.

Post-mortem Notes.—Aperture in skull about as large as a crown-piece, a little below right parietal eminence. This had a sharp, ragged margin, and the inner table of skull was splintered off for about half an inch from the outer; no more fragments of bone present. On looking through the aperture a large cavity was seen in the brain, containing thick pus and the remains of the hernia cerebri. The membranes were adherent to the bone just at the margin of the aperture. There was no general meningitis. There was no suppuration in the diploe, nor any pyæmic abscesses anywhere in the body. The brain substance was destroyed to a great extent, viz.—the supra-marginal convolution, anterior part of the angular, and the white substance above the descending cornu of the lateral ventricle as far inwards as the outer border of optic thalamus. The hernia cerebri was as large as the thumb, and was lying attached by its base to the brain substance at the middle of the abscess just described. There was a superficial abscess beneath the pia mater, over the superior and middle transverse frontal convolutions, destroying the grey matter. No marked congestion of brain.

You notice by comparing the symptoms that these two cases, though both fracture of skull followed by hernia cerebri, were very different in character; both of them were followed by inflammation, but one, the child, was inflammation of the membranes; while the other, the man, was inflammation of the brain substance.

In many cases both the membranes and the brain substance are affected; so it has been said that there are no symptoms by which the two diseases, when following a fracture of the skull, can be definitely diagnosed; but in the two cases before us it was tolerably clearly observed in the commencement what was the sequel of the injury.

The thermograph was markedly different in the two cases; in the child (meningitis) it was 104° on the third day, and though it appeared to be lowered by the action of medicines for a few hours at a time, yet throughout the disease it hovered between 105° and 103°. On one occasion she was immersed in water and

gradually cooled down to 95°, and her temperature in the axilla was reduced to 100°; but it was only the result of the cooling of the skin for a few minutes after leaving the bath; it had again reached 103°.

In the man (the abscess of the brain) the temperature likewise rose to 104° on the third day, but lowered to 101° on the following day, and throughout the rest of the time hovered between 99° and 101°, being mostly about 100°, except on the day of death, when it rose to 101.5°.

In the girl the pulse rose rapidly, being 108 on the day following the accident, then 120 and 125; and although on one day, the 26th, it counted only 98, on the 27th it rose again to 125, 140, 164, and on the day of the death 190.

In the man the pulse was quite different, being stated about 66, good strength, until more than three weeks after the injury, when it is noted 108, after which it rose rapidly to 138 and 150.

Both cases, though suffering from fracture of the skull, with depression and with laceration of brain, yet appeared at the time very little affected by the injury; both were quite conscious, could walk about the room, and gave a full account of what had happened.

The girl (meningitis) lived but eight days, and showed a series of symptoms each more serious than the preceding, indicative of a fatal result. The vomiting set in early, with rapid pulse and high temperature; then on the fourth day convulsions, lasting a few minutes, and in the evening paralysis of the left side of the face and left arm and leg. On one day only, the fifth, was there any sign of improvement, and then the leg movements were better; pulse 98, temperature 102°; but on the following day great change for the worse, convulsions, screaming, paralysis of the left side and face more complete; then came loss of power over bladder and rectum, dilated pupils, and death.

The man, encephalitis, was a month under treatment. Vomiting and high temperature and convulsions, lasting a few minutes, were among the early symptoms, but they soon ceased after removal of the fragments of bone. He was said to be somewhat delirious at night, but he was rational, and even bright, during the day. Transient convulsive seizures lasting only three minutes, occurred on the 1st, 7th, and 9th days after the injury. Not until the 15th day did the more severe symptoms set in; then came a rigor; on the following day, drowsiness and loss of memory; restless night, delirium, dragging off the bandages, muttering, and fidgeting. On the 26th day after the injury paralysis of left face, water passed involuntarily, finally unconsciousness, and convulsive twitching at periods over the last four days.

The symptoms of the two cases are characteristic, the one of an acute inflammation of the membranes of the brain; the other, of a subacute inflammation of brain substance terminating in suppuration, the setting in of which was recognised by the rigors on the 15th day.

The treatment adopted was the application of ice to the shaven head; and in the case of the girl, antimony and opium to overcome the early stage of inflammation, aconite to reduce the pulse and temperature, and afterwards large doses of quinine. In the man bleeding and leeching and calomel were employed to prevent inflammation. In both the treatment was unsuccessful, and indeed in a vast majority of cases in which the dura mater is impaired, whatever treatment is employed, success is not the result, though we occasionally hear of some very severe injury to the brain healing without development of any serious symptoms. I have myself known of a case in which craniotomy was performed, and a sufficiency of the brain removed for the labour to be carried on. The child was thought to be dead, but at the following visit it was found that he was still alive, and I may tell you that that child is still alive at the age of twenty-six; and though he has lost a very large quantity of his brain, he has yet sufficient for the purposes of a farm labourer.

In the year 1870 Mr. Fairlie Clarke brought before the Pathological Society an interesting case of recovery after compound fracture of the skull with loss of brain substance. The patient, a boy of twelve years of age, was watching a crane in an iron foundry, when the chain snapped and struck the boy on the head, fracturing the right parietal and the frontal bone, and tearing away part of the dura mater and brain substance. The injury was accompanied by profound stupor, stertorous breathing, and an almost imperceptible pulse. In twenty-four hours the boy began to recover consciousness, and from that time improved. A large hernia cerebri protruded from the wound, which was gradually reduced by bandaging. In ten weeks after the injury the boy was exhibited before the Society. The wound was then nearly healed, but there was a large scar, and at each beat of the heart the skin rose and fell. There was no pain or vertigo produced by pressing of the cicatrix. Sight and hearing were perfect, and speech unaffected. He then returned to work at the iron foundry.

The Gulstonian Lectures

ON

STERILITY IN WOMAN.

*Delivered in the Royal College of Physicians, London,
February, 1883.*

By J. MATTHEWS DUNCAN, M.D., F.R.C.P.L.,
Physician-Accoucheur and Lecturer on Midwifery at
St. Bartholomew's Hospital, &c.

LECTURE II.—PART I.

ITS THEORY OR CAUSATION.

MR. PRESIDENT, VICE-PRESIDENT, AND GENTLEMEN,—In studying the theory, or inquiring into the causes of sterility in woman, it is advantageous to keep in mind the corresponding condition in plants and in the lower animals; for in all living beings there is more or less similarity of the sexual organs and offices, and disturbance of function in one division will throw light on disturbance in another. On this subject I have made many, but only casual, observations, and have had the privilege of conversation with gardeners and breeders, classes of men in whom are found many of remarkable intelligence and acuteness of observation. But the great storehouse of facts and references on which I rely is Darwin's "Variation of Animals and Plants under Domestication." Plants and some animals propagate otherwise than by sexual generation, but it is only the sterility arising from disturbance of the regular course and consequences of sexual union that has a direct or nearly direct bearing on the present inquiry. The sterility of hybrids, which, considering the theory he is supporting, forms naturally the main study of Darwin, is of comparatively little interest to us, and will not be hereafter referred to, but many of the principles of sterility find strong support in the special sterility of hybrids.

Viewing the subject generally, we may anticipate a great result by pointing out the paramount prevalence and paramount potency of constitutional conditions as causes of sterility. Such are cold and heat, overfeeding and underfeeding, youth and old age, degradation of general health, confinement, and interbreeding.

Local conditions occur in plants that are quite sufficient to account for or cause sterility. Such are contabescence of anthers, monstrous flowers, double flowers, seedless fruit. These local conditions are the result of the general or constitutional conditions of the individuals in which they occur; and they have their place rather in the results of sterility, or of the conditions producing sterility, than in the causes of sterility. They have their analogues in such abortions, dead fetuses, unhealthy offspring, or monstrous products of animals are believed to be results of what may be called the sterile diathesis. The causes of sterility are causes of these imperfections, and for that reason they are referred to the sterile tendency. They do, indeed, constitute the sterility to be accounted for. Thus, to wander into hybridism for an example, it is an observation of Gärtner that hybridism

in plants, a great cause of sterility, produces also a strong tendency in flowers to become double.

In the vegetable kingdom everyone has observed that source of sterility which may be, no doubt nearly truly, designated a degradation of general health. A plant covered with flowers is brought from a house where its fertility has been stimulated to the highest degree, and placed as an ornament in a sitting-room, where it remains till its charms are lost, and the result is such an injury to its constitutional vigour that it is sterile, or nearly sterile, for one or for several subsequent seasons. Its fertility may never be restored, or only after several years of the medical care of a skilful gardener. The scarlet geraniums which are brought from their healthy homes in full bloom to adorn the houses of inhabitants of densely populated cities soon show the injurious influence of their new surroundings, however well they may be cared for; their flowers become less numerous, or are altogether wanting; then their leafage diminishes greatly in quantity, and their existence becomes a mere lingering. A rose garden, lately in a suburban position near London, gets surrounded by the growing city, and gradually as the buildings increase the fertility of the roses diminishes; the garden becomes useless. Some of our finest forest trees, and among them some plants, grow beautifully in our squares, producing wood in even exaggerated quantity, and a clothing of leaves sufficient for ornament; but there is no wealth of leaves, and there is no seed. In some cases an exception makes the rule more striking, as when a cherry tree in the heart of the city of London lately produced flowers and matured its fruit, so far as maturity is indicated by beauty, size, and taste.

Practical gardeners attribute sexual injury to overstimulation by manure, or what they call overfeeding. This ordinarily produces great growth of the tissues; and when this is restrained by judicious pruning, it forces out a large or excessive crop of flowers and subsequent fruit. In the language of Spencer, there is produced by overfeeding an excess of individuation, the restraint of which results in excess of genesis. The natural tendency of the overfeeding of plants is to produce a degree of relative sterility; and this may show itself in paucity of flowers, or it may show itself in the production of those double, or monstrous, or abortive flowers which are so much admired. The opposite result is produced by moderate or full feeding. Then, in mature plants there is not great growth of tissues, but rather a production of fruit. Sometimes the plant, without assignable cause, but especially if underfed, has an exaggerated production, and is said to run to seed; and, from whatever it may arise, it in a reflex manner injures the plant, which consequently becomes blighted and often dies. Excessive production here seems to take the place of sterility.

The following is an interesting illustration of the effect of overfeeding and of moderately feeding or underfeeding a vine, and it is important because it specifies a particular local condition or disease which is apparently the cause of the infecundity of the overfed plants, and so indicates a line of investigation which may with advantage be pursued in other examples of sterility. In a recent letter from Mr. Thompson, the well-known vine-cultivator, he writes:—"A circumstance has arisen in my own experience that I have never seen noticed in print. A vine called the Alnwick seedling, if grown vigorously in rich soil, fails to set its fruit even when aided. This failure is caused by the exudation from the female organ of a dewdrop of sap, which moistens the pollen, and it does not descend through the pistil and impregnate the ova. When the vine is grown in poor soil the dewdrop does not appear, and impregnation takes place; seeds are formed in perfection, but the pulp for which the grape is grown is almost absent. I know (he adds) no other grape affected in the same way or subject to the same influences."

I know no good account of the sterility of plants as regulated by age, but the influence of age is well recognised. A young fruit tree bears no fruit, or very little, and that little imperfect, and the careful gardener does not permit it to bear much or even a little, believing that fruit-bearing injures growth and diminishes future fertility. The influence of old age and decay in fruit-bearing trees is also well known: the fruit is ill-developed, and there is little of it.

"All know," says Spencer, "that a pear tree continues to increase in size for years before it begins to bear, and that, producing but few pears at first, it is long before it fruits abundantly. A young mulberry, branching out luxuriantly season after season, but covered with nothing but leaves, at length blossoms sparingly, and sets some small and imperfect

berries, which it drops while they are green; and it makes these futile attempts time after time before it succeeds in ripening any seeds. But these multiaxial plants, or aggregates of individuals, some of which continue to grow while others become arrested and transformed into seedbearers, show us the relation less definitely than certain plants that are substantially, if not literally, uniaxial. Of these the cocoa-nut may be instanced. For some years it goes on shooting up without making any sign of becoming fertile. About the sixth year it flowers, but the flowers wither without result. In the seventh year it flowers and produces a few nuts, but these prove abortive, and drop. In the eighth year it ripens a moderate number of nuts, and afterwards increases the number, until, in the tenth year, it comes into full bearing. Meanwhile, from the time of its first flowering, its growth begins to diminish, and goes on diminishing till the tenth year, when it ceases."

The evil influences of interbreeding is a subject too extensive to enter upon at any length. In plants it is corroborated by the well-known advantage of crossing of varieties. But it needs no confirmation, for there are self-impotent plants—plants more thoroughly fertilised by a nearly-allied species than by pollen of their own species, and there are the wonders of dimorphism with sterility arising from union of individuals not only of the same species, but of the same form. In the works of horticulturists it is to be found ample evidence that interbreeding of plants tends to weakness, malformation, and sterility.

The influence of heat and cold is, in plants, well illustrated by the failure of most alpine species to produce flowers and fruit in lowland gardens, and the same failure of lowland plants as they ascend the sides of mountains. A walk in the highlands will show the pines thriving on the hill sides and well covered with cones, but as greater altitudes are reached the trees are observed to become stunted, and the fruit entirely to fail.

The abortion-like sterility of plants is illustrated by the bearing of double flowers—of flowers whose seeds do not ripen, or whose seeds, though apparently perfect, are incapable of germination and growth. In some of the cases of seedless fruit, and of fruit with few seeds or with one seed, or with imperfect seed, we have also abortion, and at the same time a fine illustration of the working, locally, of the opposition between individuation and genesis. The whole plant, as the vine or the pear tree, may have the appearance of health, and its fruit alone is unnatural. The tissues of the fruit-capsule are enormously developed, while the seeds have disappeared, or are reduced to one or a small number. The luscious pear or the juicy grape are masses of hypertrophy or myxomatous-like degeneration, while the seeds are the subject of extreme hypoplasia. Gardeners generally ascribe these results to over-feeding and over-stimulation by manures and heat; but Darwin is more cautious, and in most cases does not analyse the causes farther than is implied in "unnatural conditions of life." No one, according to Lindley and Darwin, has produced double flowers by promoting the perfect health of the plant.

Before leaving vegetable physiology, I would point out the frequent occurrence in plants of seeds which, though apparently perfect, will not germinate; they cannot be distinguished from their neighbours otherwise than by their incapacity for growing. The same failure to grow is often observed under closely similar circumstances in the eggs of the fowl and of other birds; they cannot be hatched, although no imperfection is discoverable in them. That there are such ova in other animals and in woman is highly probable, but in them the completeness of the demonstration is unattainable.

Very little is known of the sterility of animals, and it is easily understood that reliable observations can only, with great difficulty, be made on them, especially in a state of nature. Many authors, and latterly Darwin and his collaborators, have paid much attention to the great subject of the sterility of hybrid animals. Observations and experiments in this department are made chiefly on domestic animals, or wild animals in confinement, and each experiment has a high value. But the sterility of ordinary domestic animals has been little studied. In herds of fine heifers and cows, and in mares, it is occasionally exhibited, but I have no data as to its frequency; and in cattle, at least, observations are imperfect, the animal that by sterility of one season disappoints its owner being generally at once fattened for the butcher.

It is a well-known belief among breeders, which may be

historically traced to ancient times, that when the female of any kind is made to breed when very young, she does so at the expense of permanently preventing her own growth to perfection, and she will likely produce offspring that is not of the best quality. This failure is well illustrated in the case of the common fowl and of the turkey, the progeny of chickens and of turkeys one year old being not the best of their kind, and specially difficult to rear. Fanciers breed these animals from a female two years and a male three years old. The occurrence of sterility in early and in elderly life is clearly seen, and its degree easily made out in pluriparous mammals, as the dog and pig, and in birds whose broods can be counted, and whose yearly production of eggs can be also numbered. This subject will be discussed fully when we come to consider pluriparity in woman.

Over-feeding, or the production of fatness or of obesity in the female, is well known to be hostile to fertility, to be an illustration of the opposition of individuation to genesis. By special feeding and fattening turkeys and common fowls, the hen-wife arrests almost completely the production of eggs. They may also be made fewer by starving the birds, and not fewer only, but also smaller. The birds, when highly fed, sometimes exhibit excessive productiveness, two eggs being laid daily—an instance of great intensity of fertility; but this is not regarded with favour, having, I am told by a turkey fancier, an injurious influence in their case by delay of the commencement of laying in the season following that of the excessive production. The breeder of cattle prevents, by careful management, the fattening of the females.

In respect of feeding, comparisons are made between the relative sterility of wild animals and the comparative fertility of domesticated or confined animals of the same species, but the comparisons are not quite satisfactory from the intermixture of the influences of food and of domestication or confinement; and again, in the comparisons of animals fed on rich and on poor pasture, sufficient care is not taken to ensure that the compared animals are of the same breed. With this previous reflection I subjoin an interesting passage from Spencer's chapter on nutrition and genesis: "Clear proof," says he, "that abundant nutriment raises the rate of multiplication (and vice versa) occurs among mammals. Compare the litters of the dog with the litters of the wolf and the fox. Whereas those of the one range in number from six to fourteen, the others contain respectively five or six or occasionally seven, and four or five, or rarely six. Again, the wild cat has four or five kittens, but the tame cat has five or six kittens two or three times a year. So, too, it is with the weasel tribe. The stoat has five young ones a year. The ferret has two litters yearly, each containing from six to nine; and this notwithstanding that it is the larger of the two. Perhaps the most striking contrast is that between the wild and tame varieties of the pig. While the one produces, according to its age, from four to eight or ten young ones, once a year, the other produces as many as seventeen in a litter; or, in other cases, will bring up five litters of ten each in two years—a rate of reproduction that is unparalleled in animals of as large a size. And let us not omit to note that this excessive fertility occurs where there is the greatest activity—where there is plenty to eat and nothing to do. There is no less distinct evidence that among domesticated mammals themselves, the well-fed individuals are more prolific than the ill-fed individuals. On the high and comparatively infertile Cotswolds it is unusual for ewes to have twins, but they very commonly have twins in the adjacent rich valley of the Severn. Similarly, among the barren hills of the west of Scotland, two lambs will be born by about one ewe in twenty; whereas in England, something like one ewe in three will bear two lambs. Nay, in rich pastures, twins are more frequent than single births; and it occasionally happens that, after a genial autumn and consequent good grazing, a flock of ewes will next spring yield double their number of lambs—the triplets balancing the unipare. So direct is the relation, that I have heard a farmer assert his ability to foretell, from the high, medium, or low condition of an ewe in autumn, whether she will next spring bear two, or one, or none."

An interesting department of the sterility of animals is that which results from confinement. This seems specially to affect what are vaguely designated the noble animals. Those which are sterile show great variations; some disdain to cohabit or have lost sexual desire; others have increase of sexual appetite, and cohabit freely or excessively, but without impregnation resulting, or with the result very rarely following. Some if impregnated bring forth only abortions, or young

which are dead-born, or, if alive, feeble and ill-formed. There is, for instance, as Shorthouse has pointed out, a common occurrence of cleft palate in the lion's cubs born in the Zoological Gardens.

Among birds in confinement there are many good examples of change of sexual habits and of sterility. In some cases they have no eggs, or, if they produce, they have only comparatively few, or they may neglect the eggs when produced, or the eggs duly cared for may be incapable of being hatched. This abortional sterility arising from imperfection of eggs, as a result of confinement is well proved by experiments made in France on the common fowl. When these birds were allowed considerable freedom, 20 per cent. of the eggs failed to be hatched; when less freedom was allowed, 40 per cent. failed; when closely confined, 60 per cent. were not hatched.

The power of temperatures that are not according to an animal's nature to induce sterility is no doubt very great. Darwin mentions that Mr. Miller, a former superintendent of the Zoological Gardens, believed that the sterility of the carnivora there was increased by increase of exposure to air and cold. In winter, inadequately sheltered cows either cease to give milk or give it in diminished quantity. "And," says Spencer, "though giving milk is not the same thing as bearing a young one, yet, as milk is part of the material from which a young one is built up, it is part of the outlay for reproductive purposes, and diminution of it is a loss of reproductive power." Failure to maintain the cow's heat may entail such reduction in the supply of milk as to cause the death of the calf. Hard living, says Darwin, retards the period at which animals conceive, for it has been found disadvantageous in the northern highlands of Scotland to allow cows to bear calves before they are four years old. Roulin found that in the hot valleys of the equatorial Cordilleras sheep were not fully fecund.

The common fowl will not breed in Greenland or Northern Siberia. "In this country it is fed," says Spencer, "through the cold months, but nevertheless, in midwinter it either wholly leaves off laying, or lays very sparingly. And then we have the further evidence that if it lays sparingly, it does so only on condition that the heat, as well as the food, is artificially maintained. Hens lay in cold weather only when they are kept warm. To which fact may be added the kindred one that when pigeons receive artificial heat they not only continue to hatch longer in autumn, but will recommence in spring sooner than they would otherwise do."

On the subject of the interbreeding of animals there is a vast body of opinion as well as of facts showing its power in producing monstrosity and its ally sterility. "If we were," says Darwin, "to pair brothers and sisters in the case of any pure animal, which from any cause had the least tendency to sterility, the breed would assuredly be lost in a few generations." Elsewhere he shows that "long-continued close interbreeding between the nearest relations diminishes the constitutional vigour, size, and fertility of the offspring; and occasionally leads to malformations, but not necessarily to general deterioration of form or structure. This failure of fertility shows that the evil results of interbreeding are independent of the augmentation of morbid tendencies common to both parents, though this augmentation no doubt is often highly injurious. Our belief that evil follows from close interbreeding rests to a large extent on the experience of practical breeders, especially of those who have seen many animals of the kind which can be propagated quickly; but it likewise rests on several carefully recorded experiments. With some animals close interbreeding may be carried on for a long period with impunity by the selection of the most vigorous and healthy individuals; but sooner or later evil follows. The evil, however, comes on so slowly and gradually that it escapes observation, but can be recognised by the almost instantaneous manner in which size, constitutional vigour, and fertility are regained when animals that have long been interbred are crossed with a distinct family."

Regarding the very remarkable subject of sterility of sexual connection with special individuals only, Darwin says:—"It is by no means rare to find certain males and females which will not breed together, though both are known to be perfectly fertile with other males and females. We have no reason to suppose that this is caused by these animals having been subjected to any change in their habits of life. . . . The cause apparently lies in an innate

sexual incompatibility of the pair which are matched. Several instances have been communicated to me by Mr. W. C. Spooner (well known for his essay on cross-breeding), by Mr. Eyton, of Eyton, by Mr. Wickstead, and other breeders, and especially by Mr. Waring, of Chilfield, in relation to horses, cattle, pigs, foxhounds, other dogs, and pigeons. In these cases, females which either previously or subsequently were proved to be fertile, failed to breed with certain males, with whom it was particularly desired to match them. A change in the constitution of the female may sometimes have occurred before she was put to the second male; but in other cases the explanation is hardly tenable, for a female known not to be barren has been unsuccessfully paired seven or eight times with the same male, likewise known to be perfectly fertile. With cart-mares, which sometimes will not breed with stallions of pure blood, but subsequently have bred with cart stallions, Mr. Spooner is inclined to attribute the failure to the lesser sexual power of the racehorse. But I have heard from the greatest breeder of racehorses at the present day, through Mr. Waring, that it frequently occurs with the mare to be put several times during one or two seasons to a particular stallion of acknowledged power, and yet prove barren, the mare afterwards breeding at once with some other horse. These facts are worth recording, as they show, like so many previous facts, on what slight constitutional differences the fertility of an animal often depends."

Before leaving the subject of the causes of sterility of animals, I quote a passage from Darwin regarding the results of confinement. "Sufficient evidence," says he, "has now been advanced to prove that animals, when first confined, are eminently liable to suffer in their reproductive systems. We feel at first naturally inclined to attribute the result to loss of health, or at least to loss of vigour, but this view can hardly be admitted when we reflect how healthy, long-lived, and vigorous many animals are under captivity, such as parrots, and hawks when used for hawk-hunting, chetahs when used for hunting, and elephants. The reproductive organs themselves are not diseased, and the diseases from which animals in menageries usually perish are not those which in any way affect their fertility. No domestic animal is more subject to disease than the sheep, yet it is remarkably prolific. The failure of animals to breed under confinement has been sometimes attributed exclusively to a failure in their sexual instincts; this may occasionally come into play, but there is no obvious reason why this instinct should be specially liable to be affected with perfectly tamed animals, except, indeed, indirectly, through the reproductive system itself being disturbed. Moreover, numerous cases have been given of various animals which couple freely under confinement, but never conceive, or, if they conceive and produce young, these are fewer in number than is natural to the species. In the vegetable kingdom instinct of course can play no part, and we shall presently see (he says) that plants, when removed from their natural conditions are affected in nearly the same manner as animals. Change of climate cannot be the cause of the loss of fertility, for, whilst many animals imported into Europe from extremely different climates breed freely, many others, when confined in their native land, are completely sterile. Change of food cannot be the chief cause, for ostriches, ducks, and many other animals, which must have undergone a great change in this respect, breed freely. Carnivorous birds, when confined, are extremely sterile, whilst most carnivorous mammals, except plantigrades, are moderately fertile. Nor can the amount of food be the cause, for a sufficient supply will certainly be given to valuable animals, and there is no reason to suppose that much more food would be given to them than to our choice domestic productions which retain their full fertility. Lastly, we may infer, from the case of the elephant, chetah, various hawks, and of many animals which are allowed to lead an almost free life in their native land, that want of exercise is not the sole cause. It would appear that any change in the habits of life, whatever these habits may be, if great enough, tends to affect in an inexplicable manner the powers of reproduction. The result depends more on the constitution of the species than on the nature of the change; for certain whole groups are affected more than others; but exceptions always occur, for some species in the most fertile groups refuse to breed, and some in the most sterile groups breed freely. Those animals which usually breed freely under confinement

rarely breed, as I was assured, in the Zoological Gardens, within a year or two after their first importation. When an animal which is generally sterile under confinement happens to breed, the young apparently do not inherit this power; for had this been the case, various quadrupeds and birds which are valuable for exhibition would have become common. Dr. Broca even affirms that many animals in the Jardin des Plantes, after having produced young for three or four successive generations, become sterile; but this may be the result of too close inter-breeding. It is a remarkable circumstance that many mammals and birds have produced hybrids under confinement quite as readily as, or even more readily than, they have procreated their own kind. Of this fact many instances have been given, and we are thus reminded of those plants which when cultivated refuse to be fertilised by their own pollen, but can easily be fertilised by that of a distinct species. Finally, we must conclude, limited as the conclusion is, that changed conditions of life have an especial power of acting injuriously on the reproductive system. The whole case is quite peculiar, for those organs, though not diseased, are thus rendered incapable of performing their proper functions, or perform them imperfectly."

ON THE SOLUTION OF THE ACTIONS OF REMEDIES, AND ON THE EXISTENCE OF NERVES OF INHIBITION AS EXEMPLIFIED BY THE ACTION OF SEDATIVES AND STIMULANTS.

By HUGH OWEN THOMAS, M.R.C.S.

SEDATIVES.

THE action of physiological doses and the probable effect of therapeutic doses of many remedies have, in most instances, been deduced from observing the effect of lethal or toxic doses. Such conclusions are not trustworthy evidence of the remedial qualities of drugs, inasmuch as when the lethal condition is approached the distinguishing signs of special poisoning begin to merge, so that their identity is nearly lost. For instance, the differences between a fatal dose of belladonna and one of opium or strychnia, are less than the variations of symptoms to be noticed when the subject is under a safe or physiological dose of either of these. The effect of the fall of a balk of timber, sufficient to kill, on one person would give no information to a witness as to what would follow if there descended on another person a portion of timber too light to kill. Again, even conclusions arrived at after witnessing the action of toxic doses have been tinged by our previous opinion of their qualities. This antecedent bias has caused recent investigators to assert the possibility of certain medicines possessing, in varied doses, diverse properties—stimulating one, and depressing at the same time another structure. (a) This error has arisen from not giving sufficient attention to the fact, that each drug has a primary affinity for certain structures, thus causing a temporary defect of co-ordination.

Some writers on therapeutics have made a class distinction between sedatives and narcotics (b), this classification being based upon the various affinities of certain drugs for particular structures. I fail to see that this is justification for separating those drugs that have been termed sedatives and narcotics. To me the terms are synonymous. To place various drugs in diverse classes because they may vary in affinity for separate structures is as reasonable, as to vary the species of the different members of the human race, on account of the quality of the food they incline to. Sedatives or narcotics retard life, and their effect upon the structures, which they primarily operate upon, is to inhibit more or less their function and to cause in other structures, unaffected by the sedative, the signs of defective inhibition or want of co-ordination, identically the same signs observed after mechanical interference with such structures.

In experiments performed upon the vagus nerve, all mechanical interference, such as section, ligation, and electric shock, has been termed stimulation or excitation of the nerve. (c) This is, in my opinion, incorrect, as either of these gives rise to a shock to the nerve, arresting its action. These experiments have also shown that the nerve is capable of acquiring some degree of habituation, so that the shock from mechanical interference loses its effect, just what we observe to follow in

the use of drugs. (a) In proof that mechanical irritation of this nerve induces a condition of shock, we have the fact that atropia (true stimulant) protects the nerve from the shock consequent upon mechanical disturbance. (b) I have not as yet met with any evidence which proves the existence of any inhibitory nerve fibres in this or any other nerve.

Again, diverse qualities have been attributed to drugs from observing their mode of action varied upon the lower animals as regards symptoms in comparison with the signs of their action on man; but this fact does not inform us that any drug varies in its properties, whether given to man or any of the lower animals. (c) It only demonstrates that drugs vary in their affinity for analogous structures in the various types of animals experimented on; although one drug may give rise to varied degrees of intensity of symptoms in the several types of animals tested, yet, in all, the ultimate drug effect will be found to be identical.

Do sedatives act as direct stimulants?—I believe they do not; but their primary effect may be to simulate stimulation, and in those instances where this simulation appears it is a primary action—then, also, the sedative is exerting a minimum or medium effect only. Opium and alcohol belong to the class of pure sedatives, and their action upon the several organs of the body confirms this. Their effects can be best observed by noticing their physiological influence upon the iris, heart, blood-vessels, and viscera. If a full dose of opium, short of being a rapidly fatal dose, be given, the diameter of the pupil becomes diminished. This is caused by the drug having a primary sedative or paralyzing action upon the radiating muscular fibres, through its primary affinity for the sympathetic system of nerves specially controlling the radiating fibres of the iris. But if a fatal dose be administered, then the cerebro-spinal system of nerves, hitherto less affected by the opium, shows signs of its full toxic effect, and the circular muscular fibres of the iris also become paralysed, as evidenced by the increased diameter of the pupil. The effect of opium upon the heart and blood-vessels is to act first upon the blood-vessels, but later on the heart secondarily. Hence we have at first an increased volume in the pulse from diminished tonicity, and finally a slower rate of beat when the dose has been sufficient and has had time to influence the heart. There is also to be observed a diminution of the solid constituents in the liquid secretions of the body and a fall of temperature. All these are signs of retardation of vital changes—sedative action. The exception to these general signs of the physiological effect of opium is to be met with when small initial doses of opium are given; then may be noticed acceleration of pulse and vomiting, which may be thought to indicate stimulation rather than retardation.

In explanation of this clinical fact, which appears to disprove my contention, I advance the following reasons:—(1) This simulated stimulation is only temporary, and is evidence that the drug has affected only those structures for which it has a primary affinity—the time being too short or the dose too small for its full physiological action to have been developed; and thus the phenomena of the so-called defective inhibition or want of co-ordination appear,—this is often interpreted as indicating stimulation. (2) That by the use of any remedy there is introduced into the system a foreign body, which may give rise to some temporary constitutional disturbance until some amount of habituation has been acquired. We have many familiar examples of this,—as change of air, diet, pleasure, relief of pain, sea voyage,—yet no physician would advise a trip to sea in place of prescribing an emetic, the latter being nearer at hand and more certain of action. So with opium, its indirect effect in simulating stimulation is not so ready or so safe as employing a genuine stimulant, when the effect is desired. (3) Some remedies, are, at times, modified in composition by the condition of the secretions which they become mingled with after introduction into the body,—this change of character, being frequently influenced by the age of the patient. Any experienced practitioner must know how rarely any of the signs of so-called stimulation comes on after the administration of opium to subjects under the age of ten years; yet how frequently are we disappointed in its action when given to patients who have passed the meridian of life, the intestinal secretions then being in many instances probably abnormal,—for, if the remedy be given by the skin method in preference

to the mouth, an unalloyed sedative effect follows. (4) The most probable explanation of the non-occurrence of vomiting after the administration of opium I believe to be that in some subjects, especially children, it rapidly affects the pneumogastric nerve and its branches, so that defective co-ordination is avoided and thus the stomach and intestines remain quiescent. In proof of this there are the observed clinical facts that only large doses produce vomiting at the commencement of their action, or at the termination of their action, *i.e.*, when the pneumogastric nerve has not been yet reached by the drug or its influence on the nerve is waning, this nerve being affected later and recovering earlier from the drug than the sympathetic nerves. There is further proof in the fact that when opium is given by the skin method its action is rapidly operative all round, and the period of possible and isolated excitement of the pneumogastric nerve and its branches is bridged over so that vomiting is avoided. This explanation of the phenomena of vomiting after the use of a sedative is quite consistent with what we observe of the effect from doses of belladonna, which also induces vomiting occasionally.

Many of the prevailing errors regarding the therapeutic effects of both opium and alcohol have arisen from misinterpretation of the signs of their action, and of the symptoms of the disease which they were required to correct.

Alcohol in its various forms, as in popular use, I maintain to be a drug possessing purely sedative properties, and in its method of action is allied to opium. It primarily affects the sympathetic nerves, then the vagus, and finally the cerebro-spinal system. When the nerves become subject to a full non-toxic dose, the pupil contracts; but soon after a fatal dose has been taken, the pupil dilates some time before death. (a) The action of alcohol upon the heart and blood-vessels, through the vagus and sympathetic system, is also analogous to that of opium. Primarily it attacks the blood-vessels through the sympathetic nerves, diminishing their tonicity,—thus relieving the heart from blood pressure,—so that the initial signs of its action may be a temporary acceleration of the pulse, as well as an increase of its volume, simulating stimulation; but if the dose is sufficiently increased, then the heart is also affected, and the pulse becomes reduced in rate.

Again, by alcohol, the solid constituents of the liquids secreted are diminished, and the normal quantity of carbonic acid exhaled by the lungs is reduced; and in corroboration of these ascertained data there is to be observed a fall of temperature. All these signs point to a purely sedative result—retardation of life, no acceleration or stimulation. The simulated signs of stimulation by alcohol arise from the primary affinity that certain doses of alcohol has for certain nerve structures, and a misinterpretation of the signs of its primary action has engendered the belief that true stimulation is gained; and though sometimes this mistake in practice may do no harm, yet when true stimulation is required its administration would be a serious error. Its primary effect can not be a safe substitute when stimulation is urgently demanded and requires to be continued. It may be argued that contraction of the pupil, when influenced by alcohol, may be brought about by stimulation of the circular muscular fibre of the iris, and not by paralysis of the radiating muscles; but the only explanation admissible regarding the mechanism of the increased volume of the arteries when influenced by alcohol, enables us to check our deduction regarding the mechanism of the action of the iris under its influence. If this drug could stimulate, the diameter of the blood-vessels would be lessened from contraction of their circular muscular coat. Again, if alcohol could stimulate, then its primary affinity for structures specially under the control of the sympathetic would cause this stimulating property to influence first the radiating fibres, and dilatation would be the first alteration observed in the pupil during its first stage of action.

Calabar Bean.—Other neurotic sedatives act, after introduction into the human frame, much like opium and alcohol. I have observed the action of Calabar bean frequently during latter years, when prescribing it for chorea, tetanus, and the muscular spasm attendant upon fractures of bones. I have observed that its action has many signs in common with opium and alcohol. In the early stage of its action the sympathetic nerves first begin to feel its effect, and we have vomiting and purging, from its delayed effect upon the pneumogastric branches of nerves supplying the

muscles of the intestinal muscular coat; but as soon as the sympathetic nerves succumb to its influence, then the cerebro-spinal nerves are inhibited also, and the striated muscles relax. The heart is nearly as much inhibited by this drug as it is by digitalis, but its sedative action upon the heart is greater than that of opium or alcohol. During the physiological action of Calabar bean the pupil becomes contracted from palsy of the radiating muscle of the iris, but as soon as a lethal dose is operative the pupil before death dilates, showing that other nerve centres have been influenced. (a) Henbane, another drug of the sedative class, during its primary action dilates the pupil, and this is explicable by the fact that henbane possesses a primary affinity for the cerebro-spinal nervous system. (b) Experiments have shown that the striated muscles are first controlled by it; secondly, the sympathetic; and finally the vagus becomes inhibited, so that, the pulse, accelerated during its primary action, is finally reduced below the normal rate.

Digitalis, again, is a sedative that possesses a primary affinity for the vagus, and is practically useful in influencing the important organs to which the nerve is distributed. During its primary or physiological action it has no effect upon the muscles of the iris, and the anatomy of the nerve, which digitalis primarily affects, excludes the probability of the iris being influenced until a lethal dose of the drug has been taken and other nerve centres have become poisoned by it, then the pupil dilates before death. When the merits of various anaesthetics are discussed, ether is frequently incorrectly referred to as a heart stimulant, when the proper explanation of its merit should be that its affinity for the heart, probably through the vagus, is less than that of chloroform, and from this it is a safer anaesthetic. In the action of septic poisons there are examples of special affinity for various structures, these so operating that the so-called signs of defective inhibition or want of co-ordination become the distinctive signs of special diseases.

In the medical practices of the future, this selective affinity for certain structures, possessed by contagious and infective poisons, will become a basis for the selection of aids in treating the diseases which these poisons cause, in place of the present tendency to attempt to neutralise the original evil by a general antiseptic saturation of the blood and tissues, that in future we shall have more of physiology and pathology, and less of chemistry, to guide the physician.

Clinical Records.

CASHEL UNION HOSPITAL.

NOTES ON THE EMPLOYMENT OF SURGICAL APPLIANCES IN HOSPITAL PRACTICE.

By THOMAS LAFFAN, Surgeon to the Hospital.

Sayre's Jacket and Spinal Curvature.

MANY who recollect the *furor* which this surgeon created a few years ago by his plaster jackets, which were vaunted as specifics for every form of spinal disease, must be anxiously on the look-out for reports of cases which would enable them to compare their own experience with those of others. I have now treated several cases, both of lateral and of Pott's curvature, from time to time, and I am sorry to say that in the first class of cases the results have altogether failed to realise the promises of Dr. Sayre. *A priori* considerations are opposed to his plaster jackets for lateral curvature, and I venture to state that if others would candidly publish their experiences, instead of being deterred by fears of adverse criticism, practical experience would equally contra-indicate their employment. I am willing to allow that there is a percentage of cases where the disease is slight, and the need of rest but brief, in which they may with advantage be used. I have kept on jackets, putting on fresh ones from time to time, for fifteen months, until compelled by the deplorable condition to which they reduced the patients to take them off, and I have found the

spine to become as deformed subsequently as if no jacket had been used. In cases of Pott's curvature I have not failed to obtain cures in most instances, and I think their employment is as logical in this class of cases as it appears to me to be illogical in the other.

Martin's Bandages.

I have given these an extended trial, and have often, not always, had reason to be gratified that through their use bread-winners have been enabled to continue at work, when, but for them, they would have had to go to hospital, and condemn their families to destitution. They appear to me, however, to delay the healing process when this latter has attained to a certain point, I think by desanguinating the granulations. I have found them of as much value in preserving healed ulcers from breaking out again as in healing existing ones.

Relative Value of Silver and Mare's Catheter.

I have had a large number of cases of prostatic retention from time to time, and have been so struck with the greater span of life secured by the French instruments, other things being equal, that I never employ a silver instrument now; and I am so deeply impressed with the superiority of the French instruments that I think the point worthy of place in these notes.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 9TH.

ANDREW CLARK, M.D., LL.D., President, in the Chair.

MR. RICKMAN J. GODLEE on a case of

FRACTURE OF THE RADIUS AND DISLOCATION FORWARD OF THE ULNA AT THE WRIST, IN WHICH THE LOWER END OF THE LATTER BONE WAS REMOVED TO EFFECT REDUCTION.

The patient, *set.* 20, was jumping a high jump at a gymnasium, when his feet slipped forwards on a badly secured mat, and the whole weight of his body fell suddenly on his hands, which were placed behind him. The left radius was fractured at the junction of the middle and lower thirds, the fracture being compound; the lower end of the ulna was displaced forwards and projected in front of the carpus beneath the skin. All attempts at reduction both with and without an anæsthetic proved unsuccessful. An incision was made over the lower end of the ulna and a hook passed under the tendon of the flexor carpi ulnaris which had slipped behind the bone, but the bones could not be replaced until first the styloid process and then the lower end of the ulna had been sawn off. The wound was treated antiseptically and healed without any inflammatory disturbance. In ten days it was placed in a plaster of Paris apparatus, and in about six weeks passive movement was commenced. The limb is now almost as useful as the other, and can be employed for gymnastic exercise as well as the ordinary uses of life, but pronation is not quite so free as before. The patient was shown.

MR. LUCAS described a somewhat similar case which came under his care in the autumn. A woman had fractured both radii, that on the right being an ordinary Colles' fracture; on the left side there was a compound fracture with protrusion of both ulna and radius. Reduction was effected with less difficulty than in Mr. Godlee's case, but erysipelas setting in, amputation had to be resorted to in spite of which, however, the patient died fourteen hours afterwards. The lower fragment of the radius was found in front. Mr. Godlee had made use of anatomical facts he (Mr. Lucas) pointed out six years ago, that *viz.*—the muscles of the radial side more than counterbalanced those of the ulnar side of the forearm. He regarded excision of the lower end of the ulna as a perfect operation; no opening into the joint being entailed by it.

MR. HEATH said he had removed the lower end of the ulna in a certain case last year, with the result that recovery ensued, the patient having a good, useful hand. Such operations were a great advance on those which involved amputation as a means of treatment.

MR. GODLEE briefly replied.

DR. PEARSON and DR. BROADBENT on a case of

ACUTE NECROSIS OF THE RIGHT ORBITAL PLATE OF THE FRONTAL BONE IN A GIRL, *ÆT.* NINE YEARS AND EIGHT MONTHS.

Four days after exposure to cold on a foggy November afternoon, symptoms of stiff neck, relaxed throat, causing restless nights, began, but so gradually that medical attendance was not called in till the fourth day. When first seen, the noticeable point in the case was that the child put both hands to her head to lift it when asked to sit up in bed. On the fifth day of the disease there was marked improvement, after a saline aperient and four grain doses of salicylate of soda every four hours. In the morning the right upper eyelid had got puffy, but the swelling went down again. There were slight droppings of blood from the nose three several times during the day. On the sixth day, after a restless night, with some wandering, followed by a morning sleep of two and a-half hours, the child woke up sufficiently well to listen to fairy tales and talk about them. She felt the neck so much better that she volunteered to get out of bed alone to show her throat, but still holding one hand lightly to the head. There was some sensitiveness to light, and the right eyelid was again puffed. The same evening great restlessness set in, the child throwing the legs and arms about and calling out. The tumefaction of the right eyebrow had now markedly increased, and there was strong delirium. The temperature at 11.30 p.m. was 103.3; pulse, 140; respirations, 38. Bromide of potassium was added to the salicylate mixture, and, after a sleep of an hour and twenty minutes, the pulse was 120, and temp. 101.6. On the seventh day the right eyebrow was quite tense and glazed and livid with tumefaction, and delirium continued. At 10 a.m. the temperature was 104°. Two leeches were applied to the right temple, and three grains of calomel were given, to be followed by a saline purge. Towards evening the strength perceptibly diminished. Just after midnight the pulse was 138; respirations, 52; temp., 105.7. At 4.30 a.m., temp. 106.4; 6.30 a.m., temp. 107.7; at 9.45 a.m., temp. 107.9; and death took place at 10.45 on the morning of the eighth day from the commencement of symptoms. *Post-mortem examination five hours after death.*—At once on removing the scalp the frontal portion of the longitudinal sinus showed itself over-charged, staining the periosteum externally. On lifting the brain, the dura mater covering the petrous portion of the right temporal bone was found smeared with thick yellow lymph. The same lymph smeared the pons and the parts comprised in the circle of Willis. The right temporo-sphenoidal lobe of the brain was protuberant, due to serous infiltration from obstruction to the venous return. The right optic nerve and the fat surrounding it were stained with the same clinging yellow lymph. The periosteum of the right orbital plate of the frontal bone was stained with inflammation, and destroyed in patches.

MR. GOULD inquired whether any pulsation in the orbit had been noticed in this case.

MR. BLACK asked if there had been any appearance of fluctuation, for if so, advantage would probably have resulted from relieving the pent up pus.

DR. MAEOMED said he had lately examined a case of necrosis of the orbital plate of the frontal bone, in which erysipelas had been suspected from the existence of a reddish blush on the face. Was anything of the kind observed in Dr. Pearson's case?

DR. BROADBENT explained that neither pulsation nor fluctuation had been discovered in the case; the swelling was soft, and gave no indication of tension. The chief mischief was on the cerebral side of the bone, the dura mater having been penetrated in several places, but the periosteum of the orbit had escaped. The swelling was mainly due to infiltration by serum of the orbital contents. He confessed that he had not fully appreciated the true nature of the case at first.

DR. PEARSON expressed an opinion that the yellow serous infiltration might, had the case progressed, have degenerated into pus, but it ran so rapid a course that this had not occurred before death. There was no pulsation, fluctuation, or any appearance of erysipelatous inflammation.

DR. GEORGE JOHNSON on

PICRIC ACID AS A TEST FOR ALBUMEN AND SUGAR IN THE URINE.

Although picric acid has for ten years or more been used as a test for albumen in the urine, its value has not been fully

appreciate. It may be used in the form of a saturated aqueous solution, made by dissolving the crystals in about fifty times their volume of boiling water, or in the form of powder, which may conveniently be carried in a pocket-case. The solution poured on the surface of the urine in a sloping test-tube will cause opalescence in a specimen of albuminous urine diluted much beyond the point at which nitric acid fails to act. The powder or crystals, equal in bulk to a peppercorn, when shaken up with about a drachm of urine, will be dissolved, and immediately coagulate any albumen present. Picric acid boiled with a solution of potash is a most delicate test for glucose. The reduction of yellow picric to the deep-red picric acid by glucose when boiled with potash, although noticed by Braun nearly twenty years ago, appears not to have been utilised as a practical test. ℥j. of a solution of grape sugar, gr. j. to ℥j., is mixed with 3℥ of liquor potasse (B.P.), m. 10 of a saturated solution of picric acid, and made up to ℥ij. with distilled water. The mixture is placed in a boiling-tube ten inches long and three-quarters of an inch wide, having a mark made at the height of ℥ij. It is then heated to the boiling-point, and kept boiling for sixty seconds. The resulting colour indicates gr. $\frac{1}{4}$ sugar to ℥j. This colour may be exactly imitated by a solution of acetate of iron, with excess of acetic acid, which is used as a standard in making a quantitative analysis. The depth of colour is directly proportioned to the amount of sugar present to decompose the picric acid. When the colour is deeper than the standard, the dark liquid is diluted until it and the standard have the same tint. The dilution is effected in a tube twelve inches long, divided into equal 1-10th inch and 1-100 parts. By the side is a tube of equal size, containing the standard colour. A more exact comparison of the colours is made by looking through equal columns of the saccharine liquid, and the standard in flat bottomed tubes held over white paper or porcelain. Ten minims of solution of picric acid are rather more than equivalent to the sugar (1.8 grs.) in ℥j of a solution containing gr. j. to ℥j. In making an analysis the picric acid must be in proportion to the amount of sugar. If the proportion of sugar be as high as six grains to the ounce, about a drachm of solution of picric acid will be required for a drachm of the sugar solution. When the amount of sugar is more than six grains to the ounce, the liquid should be diluted in a definite proportion before it is analysed. Distilled or pure rain water is used for dilution. Hard water becomes turbid when mixed with caustic potash. If undiluted urine is rendered turbid by phosphates in process of testing it should be cleared by filtration. The measurements and dilutions must all be accurate. The presence of albumen even in large amount does not interfere practically with the picric acid test. The accuracy of the test is proved by practically identical results from analysing the same specimens by Dr. Davy's ammoniac cupric solution, and by the picric acid and potash. Some tabular statements of results were given. An analysis of about 300 specimens of normal urine by the picric acid process indicates the constant presence of a substance capable of reducing picric acid and cupric oxide in proportions equivalent to from 0.5 to 0.7 grains of glucose per ounce, but apparently differing from glucose in the fact that it cannot be made to undergo the vinous fermentation under the influence of heat, &c.

Dr. JOHNSON gave the following directions for testing urine for albumen by means of picric acid:—The test may be used in the form of a saturated aqueous solution, or in the form of powder or crystals. To make a saturated solution, add to the powder or crystals fifty times their bulk of boiling distilled water; a portion of the acid will crystallise out on cooling, leaving a transparent yellow supernatant liquid. This solution being added to an equal volume of urine in a test-tube, immediately coagulates albumen. The coagulated picrate of albumen is soluble in alkalis. If, therefore, the urine be alkaline, it must be acidulated before adding the picric acid solution. To detect a very minute quantity of albumen, the following method is the best:—Take a test-tube about six inches long, and pour into it urine to within two inches of the top; slope the tube, and pour in slowly about an inch of the solution of picric acid, which will mix with the upper layer of urine, and the yellow mixture will become turbid with coagulated albumen, thus contrasting with the pellucid unstained urine below. Place the tube in a stand, and after two or three hours the coagulated albumen will have subsided and formed a delicate horizontal film at the junction of the coloured with the unstained stratum of urine, the yellow liquid and unstained urine below being quite free from tur-

bidity. In testing with the powder or crystals, put as much as is equal in bulk to a small peppercorn into the bottom of a test-tube, and pour in a column of urine about one inch in height. Shake the mixture briskly, and as the powder dissolves the urine becomes turbid with coagulated albumen. The object is to add as much of the test as the urine will quickly dissolve, and no more. As the powder dissolves more rapidly than the crystals, it is better adapted for testing with the dry acid. The application of heat quickens the solution of the powder, and so hastens the coagulation of the albumen. As a delicate test for glucose also, the picric acid was very reliable. It was not interfered with by presence of albumen in any amount. As a result of extended observations, Dr. JOHNSON concluded that normal urine contains two classes of bodies capable of reducing cupric oxide—viz. (1), urates, &c., and (2) saccharoids, the latter alone being demonstrated by the picric acid method.

Dr. ANDREW CLARK moved that the thanks of the Society be accorded to Dr. JOHNSON for his valuable communication, which provided an improved and facile method of proving the presence of sugar and albumen in urine.

Dr. SOUTHEY felt that they should be grateful to Dr. JOHNSON for the able illustration he had given of a method which would prove a highly valuable acquisition to clinical medicine. He had employed the picric acid test for some time past with much advantage. He thought that clinical experience showed that sugar and albumen existed in urine much more commonly than was formerly supposed. It was, therefore, important that delicate tests for proof of this should be within the reach of the physician. He considered, however, that some albumen was found in small amounts in urine according to its specific gravity; that the symptoms so set up were less dangerous than sometimes supposed.

Dr. MAHOMED insisted that what was wanted was not more delicate, but less delicate, tests for albumen and sugar in urine, and he thought it was misleading to regard the presence of a physiological quantity of albumen in the secretion as a matter possessing clinical importance.

Mr. BAKER HARDY urged that a method of detecting albumen by other means than boiling and the addition of nitric acid was very important. He had seen even large quantities of albumen overlooked by busy practitioners who depended on the older means of demonstrating it. He had himself employed the picric acid test in three such cases of failure, and in each brought down the characteristic precipitate. Recently, in the out-patient department of King's College Hospital, a man came in with a black eye, and from ophthalmoscopic examination he concluded that albumen would be found in the man's urine. On addition of picric acid no precipitate was thrown down at first, but it appeared on shaking. The man was then admitted as an in-patient with albuminuric retinitis and kidney degeneration, but both heat and nitric acid failed to show the presence of albumen in his urine, which, however, was clearly brought out by picric acid. If to a portion of urine, moreover, which has been carefully poured on to a layer of nitric acid, a solution of picric acid were gently added, indications of albumen would be seen at the junction of the picric acid and urine, in many instances, where no such signs were apparent at the point of union of urine and nitric acid. As a test for sugar, also, picric acid had been highly useful to many of his own pupils and friends. Raymond had mentioned the presence of sugar in healthy urine. Usually, however, it was masked by kreatin.

Dr. JOHNSON doubted whether albumen existed in small traces, even in normal urine, as a physiological condition. He could not either agree with Dr. Mahomed that a rough test possessed value over a delicate one; and in this connection he thought it worth while to recall the fact that Dr. Mahomed had, as they all knew, recorded several cases of granular kidney without albuminuria. Possibly he would have chronicled a different result had he been more ready to admit the advantages of a delicate test for albumen in urine.

ACADEMY OF MEDICINE IN IRELAND.

SUB-SECTION OF STATE MEDICINE

THE opening meeting of the Sub-Section of State Medicine was held on Thursday evening, February 8th, in the Hall of the College of Physicians.

Dr. C. A. CAMERON, President of the Sub-Section, delivered an introductory address, dealing at considerable length with the subject of public hygiene from the earliest times, and referring particularly to the sanitary laws and their administration in foreign states. In Plato's Ideal Republic, in the writings of Xenophon, Hippocrates, and in the theocratic legislation of the Jews, were the earliest references to sanitary laws and the duties of the professor of preventive as compared with curative medicine. In the Middle Ages little was done to promote the public health. The first general Public Health Act passed in the United Kingdom dealt exclusively with Ireland, and came into operation in 1818. A most valuable Act. The Towns Improvement Act of 1874 also dealt only with Ireland, and some of its sanitary provisions were superior to those of the Public Health Act of 1878. The fatal defect was the purely permissive nature of its provisions. The various sanitary acts were reviewed in detail, and praise given to the Irish Registrar-General, for showing the death-rate per 1,000 persons in sixteen different classes of society in Dublin in his weekly returns since January last. The sanitary organisations of the chief Continental states, and of the United States were fully described. Excepting Scandinavia, they were inferior to the British sanitary administration. The municipal authorities had very little power, and the sanitary police were altogether under the control of the Government. In some Belgian and French towns, municipal bureaux of health had recently been constituted, somewhat on the model of the British Local Boards of Health. In one department of public health, namely, the systematic inspection of food, drugs, and poisonous colours, the sanitary authorities of France, Germany, Belgium, and Holland, were more vigilant and active than is the case in the United Kingdom. In Holland a most severe system of compulsory notification of infectious diseases existed.

Dr. GRIMSHAW, Registrar-General for Ireland, congratulated the Academy on establishing in connection with it a department of public health. He then read a paper on some points concerning the relations between census statistics and health statistics. Having referred to the increase of statistics and their consequent depreciation in the minds of many persons, he dwelt forcibly on two points—first, on the errors in calculating death-rates on estimates of population founded on the rate of increase between census periods. He showed that in Ireland it was wrong to treat the towns population as stationary, as producing errors in death-rates which, however, were not greater than those founded on estimated populations. He also pointed out that estimates founded on the number of inhabited houses were also liable to serious error. With the view of classifying the population into various social grades or "strata," he made observations on the value of a social census, and said that, at the suggestion of the Dublin Sanitary Association such a census had been compiled for the Dublin Registration District, so that now it was possible to strike death-rates for various social grades of the community in that district. Since the commencement of the present year these death-rates had been struck for each year, and as the result of the experiment during the four weeks it was in operation the death-rate was as follows as compared with a total death-rate of 39.8 per 1,000:—Professional and independent class, 22.45; middle class, 25.4; artisans and petty shopkeepers, 26.1; general service class and workhouse inmates, 37.2 per 1,000.

The PRESIDENT of the College of Physicians asked whether the increase in the population in 1877-8 depended in any way on the state of the harvest. To him the social aspect of the statistics initiated by the Registrar-General was a new phase, and of enormous interest.

Dr. MACSWINEY considered statistics of the duration of life of various classes would have a most important bearing upon life assurance. The present life tables worked injuriously to the insurer. From Dr. Grimshaw's statistics it would appear that the actual expectation of life in some classes was much greater than in others, and thus the premium payable on a policy of life assurance, instead of being settled by an estimate based on the general statistics of deaths, would depend rather on the social position of the individual as the important factor.

Dr. J. W. MOORE expressed his sense of the importance of the two points in Dr. Grimshaw's paper. First, in regard to the erroneous calculation on the changes in population consequent on the distant periods at which the census was taken; and secondly, the tabulation of the social position of the population concerning death-rate. Both points were carefully attended to in certain northern nations, local estimates being made every two years, particularly in Copenhagen. He took exception to the grouping of the wives and children of the artisan in the different classes, as erroneous statistics would result. Instance the high mortality among the knife-grinders in Sheffield from the disease called knife-grinder's rot, and if they distributed the mortality over the wives and children the estimate of it in that particular trade would be a false one. He would, therefore, group together the wives and children as belonging to the artisans generally, and so with the wives and children of the middle and upper classes. Thus the individuals themselves who bore the heat and toil of the day in the various occupations would form the factors of the death-rate.

The CHAIRMAN thought that to group the wives and children of artisans would involve too great minuteness of detail, and would be unnecessary in the presence of the admirable statistics on the mean expectation of life as to persons of all ages founded on two millions of years of life in connection with life assurance in the manuals of the Odd Fellows community. Men seldom insured their lives before 21 or 22, and from the time a man started at a particular trade until he died, there was a certain amount of information as to his mean expectation of life at any particular period; but they had no such information with regard to whole classes of the population—their wives and children. He thought, therefore, Dr. Grimshaw's classification was admirable. The death-rate of Dublin was, in his opinion, greatly influenced by the relatively large population of poor people in the city in comparison with English and Scotch cities, and if there were statistics like those which the Registrar-General had collected in the last four weeks there would be data to compare the sanitary condition of Dublin with that of those cities. The income tax of Dublin was greatly exceeded by that of English and Scotch cities of the same population, showing that Dublin was the poorest. Dr. Grimshaw's statistics would, in a year or two, prove the truth of his opinion.

Dr. GRIMSHAW replied. He did not think the harvest had anything to do with the increased population. An estimated increase in 1876, of 10,528, and in 1877, of 7,613; but that it was due to the labour market in America being then extremely low; and so when the labour market rose towards the end of 1879, the movement of the population to America increased, and was stimulated by the bad harvest here. As to Dr. MacSwiney's point concerning life assurance, he had asked several persons connected with assurance companies whether they really considered the high death-rate in Dublin had any effect in measuring the premium, and they said not, that insurance business paid as well in Dublin as anywhere else. As to Dr. Moore's point, he submitted that the death of a tradesman, for instance, from knife-grinder's rot, affected his family, as the family might starve. The chairman's point about the income tax he did not consider sound. Income tax was paid by persons of great incomes. There was a large class of persons in English towns from £20,000 to £40,000 a year; while there were few such in Dublin, and no person with from 10s. to £2 a week paid income tax; the amount of income tax was no index of the death-rate. The chances of life to a man's family with £1,000 a year were just as good as in the case of a man with £100,000. At a certain level of comfort there was no difference in the risk to life. Mr. Wilson, of his office, had two years ago suggested the social classification adopted.

Thanks were voted to Mr. W. R. Maguire for having exhibited a most interesting collection of sanitary appliances and models. The Sub-Section then adjourned.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

STRANGULATED HERNIA.—The reduction of strangulated hernia by subcutaneous injection of morphia first employed by Dr. Phillippe, of St. Maudé, renders excellent services every day, and consequently, many practitioners in the country where either the want of proper instruments or the prejudice or unwillingness of the peasants to submit to an operation are serious obstacles to be got over, adopt this method in almost every case, and rightly so, as the effects are sometimes marvellous. A country surgeon has just published a report of eight cases treated thus by him with two failures. The taxis and all ordinary means failed, and colotomy seemed the only resource. Twice the reduction was impossible, and the patients having refused to be operated upon would have infallibly succumbed. In one case to which he was called everything was ready for the operation, the patient consenting, when he proposed to inject a quarter of a grain of morphia over the strangulation. A quarter of an hour afterwards the hernia was reduced without difficulty. Sometimes the delay is longer, but the pain and the vomiting ceases; hence the operation can be postponed without fear for some hours when a new injection is made and often succeeds.

TAPPING THE BLADDER.—As is well known, there existed formerly three methods of tapping the bladder, to which a

fourth might be added, which Voillemier employed, and which he called the sub-pubeal method, consisting in drawing the penis downwards and backwards, and plunging a trocar through the suspensory ligament, so as to reach the anterior wall of the bladder a little above the neck. Voillemier was the only one that practised. As to the three former methods, one of them, the perineal, was, from the difficulty of the operation, soon abandoned, the choice being left between the recto-vesical and hypogastric operations, each of which had its partisans. To-day, with the aspirator, the recto-vesical method has also nearly fallen into disuse, tapping through the hypogastric region being not only the simplest, but the least dangerous of all. Dr. Picard, who is entirely in favour of this method, yet considers that it cannot, however, be employed very often with impunity, as where the needle of the aspirator has been passed several times, phlegmonous abscesses have been known to follow. He cites the case of a patient who came before him for retention of urine, and having tried in vain to pass the catheter, he tapped him through the hypogastric region with the aspirator: he renewed the operation the following day twice, and the two succeeding days six times, after which he was able to slip through the ordinary channel a very small-sized catheter. All went on well for a couple of days, but soon the seat of the ecchymosis, the result of the little punctures, showed signs of inflammation, which eventually ended in suppuration, which necessitated a large incision and many days of treatment. M. Picard consequently concludes that, in tapping the bladder, a trocar, no matter how fine, cannot be used very often without danger, and then, when it is necessary to tap frequently, the recto-vesical method might be alternated with the hypogastric.

The Services.

IRISH STUDENTS AT THE ARMY MEDICAL EXAMINATIONS.

At the recent dinner of the Dublin Branch of the British Medical Association, pointed allusion was made by both Dr. Lyons, M.P., and Mr. Gibson, M.P., to complaints which were current, and which had reached their ears, to the effect that since December, 1879, when the Army Medical Service was reformed by the latest Royal Warrant, Irish students have been "boycotted" by the examining board, and to a great extent excluded from the service.

We were very unwilling to give any credence to a statement of this sort, and could hardly believe that there existed even an involuntary prejudice against Irish candidates which might cause them to be unfairly dealt with; but we thought it well that such an insinuation should be either justified or proved groundless. Accordingly, we entered into a careful tabulation of the results of the Army examinations, as reported each year by the department to the General Medical Council, and published by the Council in its Minutes; and we give now the results of our inquiry for what they are worth, leaving to the Army Medical examiners on one side, and the Irish teachers on the other, the task of explaining the facts which are disclosed.

In reading these figures it is necessary to keep in mind three points:—1. That they represent *not* the individuals, but the diplomas possessed by the individuals. As each

candidate must have a medical and a surgical licence, of course the number of candidates is about one-half of the number of diplomas set down. 2. That the results are stated by us as percentages of successes and rejections, so that it does not affect our argument whether there were more or fewer candidates of any one nationality. 3. That while before June, 1881, the candidates were classified simply as "passed" and "rejected," after that date the passed were again subdivided into (a) those who obtained appointments, and (b) those who were found qualified, but got no appointments.

Comparing six examinations immediately before the New Warrant with two groups of three examinations immediately after its promulgation, we find the following results:—

<i>Before Warrant.</i>				Percentages.	
Date of Examination.		Passes.		Rejections.	
14 Feb., 1875.					
Irish	8	2	
English and Scotch ...	9	2	
9 Aug., 1875.					
Irish	20	0	
English and Scotch ...	23	0	
14 Aug., 1876.					
Irish	35	0	
English and Scotch ...	45	2	
12 Feb., 1877.					
Irish	23	6	
English and Scotch ...	11	6	
13 Aug., 1877.					
Irish	30	2	
English and Scotch ...	30	0	
11 Feb., 1878.					
Irish	9	0	
English and Scotch ...	29	2	

Thus it appears that, during the period before the New Warrant, candidates holding 133 Irish diplomas presented themselves, as against others who held 139 English and Scotch licences.

It is, therefore, not true, as has been pleaded, that within this period English and Scotch surgeons held aloof from the Army Service, and left it to inferior Irish candidates.

The relative success of nationalities was as follows:—

	Passes.	Rejections.
Irish	96·8	3·2
English and Scotch ...	90·8	9·2

It is, therefore, obvious that during the period before the Warrant the holders of Irish diplomas, though not more numerous, were more successful than the competitors who held English and Scotch licences.

The New Warrant was promulgated on the 2nd of December, 1879. The following are the results of the three succeeding examinations:—

<i>After Warrant.</i>				Percentages.	
Date of Examination.		Passes.		Rejections.	
8 Dec., 1879.					
Irish	100·0	0	
English and Scotch ...	95·7	4·3	
9 Feb., 1880.					
Irish	9·4	4·0	
English and Scotch ...	·8	13·4	
14 Feb., 1880.					
Irish	86·	13·5	
English and Scotch ...	62·6	37·4	

Average of Three Examinations.

	PASSES.	REJECTIONS.
Irish	93·6	5·8
English and Scotch	80·7	18·3

It will be observed that during this period the candidates holding Irish diplomas maintained their pre-eminence, notwithstanding the increased competition and consequent stringency of examination which followed upon the improvement in the value of the Army Medical Service which resulted from the New Warrant.

But in 1881 a new system of classification was introduced. Candidates who answer up to the required standard are declared qualified, but it does not follow that they obtain appointments. From the whole number who pass, a limited number are selected for appointment, and it remains to be shown upon what ground this selection is made. Whatever the ground may be, a perusal of the results of the subsequent examinations places it beyond dispute that the selection has been altogether to the disadvantage of the Irish candidates.

Here are the figures :—

After Classification by Selection.

Date of Examination.	PASSES for Appointment.	QUALIFIED—not APPOINTED.	REJECTED.
15 Aug., 1881.			
Irish	34·6	65·3	0
English and Scotch	59·7	46·1	2
20 Feb., 1882.			
Irish	3·45	91·3	0
English and Scotch	37·7	58·8	3·5
21 Aug., 1882.			
Irish	26·6	73·3	0
English and Scotch	69·3	23·7	0

Average of Three Examinations.

	PASS for Appointment.	QUALIFIED—not APPOINTED.
Irish	21·5	76·6
English and Scotch	52·5	42·8

It is worthy of remark upon these figures that they make evident the fact that the Irish students, who were very successful *before* the new system of classification and selection, showed inexplicable deficiency afterwards; and, still more remarkable, that in the latter period the Irish students, though they were declared "qualified" in greater proportion than their competitors of the sister kingdom, and had no rejections amongst them, nevertheless received little more than one-third of the appointments.

These figures seem to us to present a very peculiar aspect. Assuming the perfect impartiality of the examiners, they require us to believe that in the six months from February to August, 1881, the Irish students developed, and have since continued to develop, a sudden access of mediocrity of intelligence, and their teachers a sudden incapacity for instruction.

It will, we anticipate, be urged that the cause of this decadence on the part of Irish candidates is that a higher standard of examination has arisen from increased competition, and that they are not up to the required level. This explanation may or may not be true; at any rate, it is a pure hypothesis which, if it be accepted, must be supported by substantial proof, clearly not derivable from the figures before us. We cannot say that the hypothesis is not true in the case of the candidates at large, but we can assert that it is not true of individual

candidates. It is notorious that candidates of special pre-eminence—men of remarkable brilliancy, unusual attainments, and a thorough capacity for answering—have gone from Ireland during this period and been refused admission to the Army Medical Service. One gentleman who obtained the first place at the M.B. examination of the University of Dublin, and who won the Travelling Prize as being the best man of his day, offered himself to the Army Medical examiners, and was qualified but not appointed, and other instances of unsuccess almost equally remarkable are known to Irish grinders.

We do not wish to adopt the theory that Irish candidates have been "boycotted," for the facts are capable of explanation in other ways. Perhaps, the London and Edinburgh "coaches" have got more complete possession of the pet questions of particular examiners than the Irish "grinders;" or perhaps, as is confidently asserted, the printed papers get into the hands of London teachers in advance of the examination. In any case some explanation of the facts is needed, and we invite further information on the subject.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 14, 1883.

THE RECENT ANTI-VACCINATION PERSECUTION.

ALTHOUGH the attempt recently made by officious anti-vaccinating fanatics to incriminate a public functionary who had faithfully discharged his duty has

signally collapsed, there are, nevertheless, several important lessons to be drawn from the occurrence. The case in question arose in connection with the vaccination, by Dr. Dunlop, Medical Officer of Health to St. Pancras Workhouse, of an illegitimate child born in that institution on December 10th. The operation was performed on the 16th Dec., and nothing was observed during the remainder of the child's stay in the workhouse to indicate any but a favourable termination. On the 24th, however, its mother, a girl of 16 only, removed to a wretched lodging, where it was impossible for her infant, which, of course, accompanied her on the emigration, to receive the care and attention it required. Exposed to untoward conditions—for it was proved in evidence that no adequate precautions were observed to assist the child's recovery—it naturally declined; redness and swelling of the vaccinated arm appeared on the sixth day from leaving the workhouse, the vesicles presented a most unhealthy look, and coma and death supervened on January 7th of the present year. Four days later a post-mortem examination showed extreme emaciation, but a healthy state of all the internal organs except the brain, over the whole surface of which a purulent deposit was found to the thickness in places over the tenth of an inch. At the instigation of the Anti-Compulsory Vaccination League, the mother summoned Dr. Dunlop on the charge of manslaughter, the accusation being that pyæmia had been induced as a consequence of vaccination. Without calling witnesses for the defence who would have placed the scientific side of the question in a true light, the magistrate dismissed the charge; and here, for the time, at any rate, the matter drops.

Apart from the petty annoyance to which Dr. Dunlop has been submitted, and under the infliction of which he has naturally received the entire sympathy of the profession, there are points raised in connection with this case which may profitably serve to excite some future discussion. Unreasoning opponents of vaccination will not, unfortunately, or cannot, appreciate the significance of the fallacy which lurks in the *post hoc ergo propter hoc* argument when applied to their particular bugbear. Had the child whose mother received such attentive treatment from the Anti-Compulsory, etc., Society been permitted to remain where it was rapidly attaining health and strength, this opportunity of persecuting an actual vaccinator would never have presented itself, for on pathological grounds it is impossible to regard as probable the theory set up by the prosecution. On the other hand, there is much to warrant the conclusion that meningitis was encouraged by the exposure and want to which the little victim was condemned; while there is overwhelming proof of the immunity from evil enjoyed by healthy children vaccinated within a week of birth. The child in this instance was, in the estimation of the accredited medical officer of the workhouse, a fairly healthy infant; and he very justly followed in respect to it the course which experience had taught him was best calculated to ensure the safety both of the child and of the community.

There can be no other explanation afforded of the action taken by the Anti-Compulsionists than that which

attributes to them a constant eagerness to justify their existence in the eyes of their supporters. We could, therefore, have wished that medical evidence proffered by Dr. Bristowe and Dr. Wilks had been received in court for the purpose of exposing the doubtful scientific value of that on which the charge was based. At the present time, animated by what they deem the promise of successful contest with truth, anti-vaccinators, or those who lead them, are using frantic efforts to win adherents to their views; and we cannot help but think that continual earnestness on the part of medical men is necessary more than ever to counteract the hurtful influences of unprincipled or interested propagandists. In courts of law there will never be found much sympathy with doctrines that manifestly act injuriously to the state; and even in the lesser and local tribunals the appearance of pro-anti-vaccination magistrates is of rare occurrence, education, as a rule, providing them with the needed apparatus of discrimination. But, notwithstanding, it is always open to a "society" to frame indictments as advertising engines, even at the expense of persecution of those who rightfully do their duty to the state, as in Dr. Dunlop's case. For the present, we must accept the unpleasantness associated with the office of right; but those who suffer a temporary inconvenience have not only the satisfaction of knowing that this is itself a reward of rectitude, but also that they thereby distinguish themselves as eminently worthy of the respect and sympathy of their professional brethren throughout the world.

THE CRUELTY TO ANIMALS BILL.

SO CALLED "lovers of sport," who, at the same time, seek to deserve the title invented by Prof. Owen to designate those who have a kindly regard for animal life, "bestiarian," will unite in accepting the Bill for amending the Acts relating to cruelty to animals which has been successfully introduced into Parliament by Mr. Anderson. In his withering denunciation of the anti-vivisection hysteria, the veteran physiologist mentioned above seeks to apply the term bestiarian to all those who have shrieked aloud for a recognition of the superior rights of animals; but in a somewhat less degree we must be content to accept the name as a proper one by which to designate supporters of Mr. Anderson's Bill, for, in a measure, the reasoning which denies the right of man to utilise living animals for his own needs in disease, would also with equal force deny his right to employ them to minister to his selfish pleasures. It is certainly a very novel position for the humane vivisectionist to find himself on a common platform with his most decided opponent. But strange as the association may seem, it must be admitted—with, however, this one reservation—that many of the bitterest anti-vivisectionists will be among the first to sever the slight connecting link thus established. Bestiarian sympathy, after all, extends no farther than to animals sacrificed to assist the advancement of scientific discovery; and it would afford us no surprise to learn that the majority of Mr. Jesse's supporters are indignantly averse to such restrictions on their playful amusements as in the near future will be imposed.

To us, who have long viewed with repugnance and disgust the brutal tortures inflicted on helpless and innocent animals for no possible purpose but the gratification of bastard sporting instincts, the prospects of a speedy effacement of this blot on our civilisation comes with inspiring promise of national improvement. One of the most curious anomalies of the century is that exhibited by a legislative assembly which willfully shuts its eyes to the claims of science, and with an affectation of horror at the cruelties it was pleased to associate with experimental research, forbade the prosecution of original investigations in this country, while at the very time it acted thus it was, by its individual encouragement of pigeon-shooting enormities, winking at and abetting such multiplied horrors as the scientific mind would shrink from contemplating.

Even now, too, when at last the spirit of justice has been evoked, legislation is rendered possible only by a partial mutilation of the anti-cruelty measure. Specified "sports" have had to be omitted from the Bill to secure its acceptance by a majority of the House; but we would fain hope that the time is not far distant which will see concession of the principle that cruelty without human gain is an unjustifiable violation of the rights that even the meanest creatures possess to life and the enjoyment of existence.

MEDICAL WOMEN FOR INDIA.

THIS question has been brought prominently before the profession of late by the papers in our columns of Dr. Gordon and Dr. Hoggan, and by articles in our contemporaries. From newspapers recently received from India we are now enabled to gauge the native views relative thereto, there being abundant evidence that the question of medical women for that country is being fully considered among the classes of persons most directly interested in it. As presented originally in England, the necessity for and propriety of sending to India ladies qualified to practise medicine appeared not to admit of a doubt; it is therefore interesting as it is suggestive to observe that papers before us give expression to very different and even opposite views in regard to both of these points. For example, one journal has the following remarks:—"The fact that thousands of women annually die in India owing to the absence of medical relief, and thousands of others continuously suffer from painful diseases for want of proper medical treatment, is universally admitted to be true." So far, however, is the "fact" above stated from being universally admitted to be true, that a journal quite as likely to be well informed on the subject as that from which we have just quoted, considers that "the picture of excessive obstetric and uterine suffering has been overdrawn; that native women, high and low, get over their confinements more speedily and with less suffering than their Western sisters; that as regards uterine disorders, it is by no means clear that they are of frequent occurrence in Indian zenanas; that our Western system of medicine has by no means become universally sought for by natives of India; that native women, when they have availed themselves of the services of medical lady practitioners, have not been at all ready to pay for those

services; that anything like the strong demand for their services in middle and high-class zenanas which is represented to exist has by no means been proved." And the same journal adds that—"Yet, on the assumption that an enormous amount of preventible disease exists among Indian women, and that in the majority of cases English medical ladies are the only qualified doctors who are allowed to give assistance," the proposal to send a number of such medical ladies to India has been advocated. A third journal, writing on this subject, appears to entertain certain doubts as to the permanency of the movement now being fostered. It asks: "Who knows that the public will remain in the same frame of mind after the novelty of the thing has worn off?"—in other words, pointing out to its readers that a *hobby* is being started, although with prospects of a brief career. Further, it says: "Let a fair start be made with Rs. 35,000—which sum has already been subscribed for the purpose in Bombay. But do not rest till you have a hospital for regular training of native ladies in general medicine, and especially in midwifery." So that the measure of sending out medical women from England, if required at all, is only to be looked upon as a make shift and temporary measure. A fourth journal alludes to the difficulty of giving the required instruction to native ladies, and imparting it to them "in a foreign tongue;" and having discussed the subject from that particular point of view, thus concludes its remarks: "We do not think the proposed plan will achieve any very great success." One of the journals already quoted remarks that "it is, however, of extreme importance that the medical women should not be mere novices, but well-skilled practitioners of experience and reputation." And herein are involved several important difficulties. If a lady medical practitioner has practised sufficiently long and successfully in England to have obtained "experience and reputation," why should she desert her practice at home to proceed, a stranger, to a foreign country and a most trying climate? Is not every consideration against such a step being taken? But how far would "experience" gained in England be applicable in India, taking into account differences of race, usages, habits, *et cetera*? Would it enable its possessor to be of greater—or, indeed, as much—use to the sick Indian woman as the ordinary native attendants on the occupants of zenanas? There appear to be no grounds whereon to base a reply in the affirmative. Altogether, then, the weight of arguments adduced in the papers quoted from is decidedly against the necessity for English medical women in India, and the likelihood of their finding either sufficient field for their intended usefulness, or remuneration sufficient to recompense them for proceeding to that country.

PRISON SURGEONS.

THIS Commission has been sitting at intervals for the last fortnight, and we understand that an application has been made to it to receive evidence on behalf of the Irish prison surgeons, who are represented—for the occasion—by Drs. MacDonnell, Carte, D. Jacob, Falkiner, and Middleton, as delegates from the Irish Prison Surgeons' Association. We understand that the Commission has suspended its sittings in order to

enable Sir R. Cross, the chairman, and others of its members, to attend Parliament. It will not resume its sittings until after July, and the prison surgeons will need to press their views at that time. We do not suppose that the Commission will arrive at a report without having made an effort to satisfy the well-grounded discontent of these officers. The policy of the General Prisons Board towards its medical officers has been one of continual and insidious encroachment, of illiberality, and of attempted bullying. By the 27th section of the Prisons Act of 1878 every medical officer then in office is required to perform "such duties as he may be required to perform by the General Prisons Board, so that the same are analogous to those they performed previously to the commencement of the Act; and, subject as aforesaid, they shall perform the same duties as nearly as may be as they shall be performing at the same date." How has the Prisons Board interpreted this clause? Its first act was an attempt to deprive the apothecaries of office, and force their duties on the medical officers without additional pay. Its next proceeding was to reduce the salaries of many such officers; and in both these attempts they were defeated by an appeal to the law. Since then the Board has lost no opportunity of humiliating and harassing the medical officers—snubbing them through the medium of the prison governor, and throwing every possible hindrance in the way of the satisfactory performance of their duty. Amongst other means of "serving out" the doctors adopted by the Board is the imposition of innumerable new functions. If a prisoner is given an extra egg daily, the surgeon is ordered to visit him as a sick prisoner, and fill up numerous reports; if any of the family of the warder outside the prison falls ill, the surgeon is—in defiance of the law—ordered to attend. As to ordinary duties, the labour of the surgeon has been multiplied without any increase in emolument whatever. He must now visit daily instead of twice weekly as heretofore, and before 12 noon instead of the hour most convenient; he must inspect each prisoner—well or ill—once a week; he must write innumerable additional reports and book-entries; and must perform gratuitously an inspection of all persons seeking admission to the prisons' service, as if for insurance. All this new work has been put upon the medical officers, without extra remuneration, and enforced by the most arbitrary and uncivil method. We do not express any opinion as to the necessity for these additional duties; but we do say that, if the Government wants double work from an officer it should pay him in proportion, and that it is a disreputable abuse of authority for any department to try to bully its servants into the gratuitous performance of duties for which it well knows they are not liable.

WE are informed that the Port Sanitary Committee have agreed to recommend the Corporation of London to erect a hospital on the Kentish shore of the Thames, in the neighbourhood of the spot below Gravesend where the hospital ship *Rhin* is now stationed, at a cost not exceeding £5,000.

Notes on Current Topics.

The Recent Small-Pox Prosecution.

THE very general sympathy with Dr. Dunlop, medical officer to St. Pancras Workhouse, is being shown by numerous acts indicative of the feeling which has been aroused by his unmerited persecution. The Council of the Poor-law Medical Officers' Association last week passed a resolution to the following effect:—"That this Council begs to express its sincere sympathy with Dr. Dunlop, the medical officer of St. Pancras Workhouse, in the unmerited persecution to which he has been exposed in the recent prosecution for manslaughter; and that this Council further expresses its satisfaction that the St. Pancras Board of Guardians should have so readily undertaken his defence, whereby Dr. Dunlop was saved from a heavy pecuniary liability. The Council also desires to thank its chairman, Dr. Joseph Rogers, for the public spirited manner in which he aided Dr. Dunlop in his defence." While they will tend to show the hearty manner in which medical men are supported by their brethren in the execution of their duty, such testimonials as this cannot fail to be signally agreeable to Dr. Dunlop, who, moreover, is well worthy to receive any such expression of sympathy that may be accorded to him.

Our Hospitals.

AT length the subject of hospital abuse is beginning to be discussed in the lay press; and the public, in whose hands the power of compelling reform largely rests, are being slowly enlightened with regard to the evils to which their mistaken benevolence too often gives rise. We commend to the attention of our readers the admirable article on this subject from the pen of Mr. Burdett in the current number of the *Nineteenth Century*. Mr. Burdett, who has devoted himself to its investigation, has fully mastered his theme, and though his suggestions have not the merit of novelty, yet they present a most admirable *exposé* of the shameful waste of public funds, and the gross impostures which the present system allows under cloak of the sacred name of charity. The sham special hospital, and the special hospital quack, for whose benefit many of these institutions exist, are accurately described. Mr. Burdett dwells upon the fact so often pointed out in our columns that, were the funds which are now wasted in maintaining these useless places distributed amongst legitimate institutions, these would probably be completely relieved of the burden of debt which now encumbers them. Mr. Burdett fearlessly exposes the system of chicanery by which the sham hospital is started and worked; and he demonstrates the fact that the sole *raison d'être* of these establishments is that they may serve as stalking horses, under cover of which unscrupulous quacks of the David Jones type may safely advertise their false claims to professional eminence, and effectually prey upon the unsuspecting public. The future of the government and internal economy of these hospitals is accurately drawn, and the conduct of those weak members of the profession who are found ready to accept office under the quack for whose benefit the establishment is kept up is justly stigmatised. The *Medical Press and Circular* alone among medical papers has had

the courage repeatedly to expose all the evils to which Mr. Bardett now calls attention. We have always deplored that the subject was not taken up by lay journals, and we rejoice that at last the public have a prospect of enlightenment. It is useless now to ask why the medical corporations and societies like the British Medical Association have not long ago bestirred themselves to root out—as they were well able—the growing evil which has now reached such great proportions; but we fear that when the public becomes fully informed of the facts, the credit and honour of the medical profession will not be enhanced when it is perceived that its leaders, instead of expelling them, have knowingly tolerated in their midst men whose lives are devoted to the amassing of wealth by nefarious means, and, what is worse, trafficking on the weakness of suffering humanity.

The Fothergillian Gold Medal.

ON Wednesday last the annual dinner of the Medical Society of London was held at the Criterion Restaurant, when the Fothergill Gold Medal for 1883, value twenty guineas, was presented to the successful competitor, Mr. Norman Porritt, L.R.C.P. The subject selected for the essays this year was "The Operative Treatment of Intra-thoracic Effusion;" and Mr. Porritt has been able to illustrate his paper with notes of no less than fifty cases in point. It may be fairly remarked how favourable the Yorkshire atmosphere appears to be to the production of Fothergillian Medalists. Two years running, 1882 and 1883, Yorkshire has produced the successful competitor, last year's medalist having been Mr. T. M. Dolan, F.R.C.S., of Halifax; while Mr. Porritt is in practice at Huddersfield. Dr. J. Milner Fothergill also was under the influence of a Yorkshire atmosphere, being at the time resident at Leeds Infirmary, when he obtained the medal bearing his name; and Dr. Broadbent is, we believe, a Yorkshireman by birth. But after all Yorkshire is an immense county, and its sons are inferior to those of no other shire in point of wits, while in numbers they exceed many.

Amputation at the Shoulder Joint.

was performed on Tuesday week in the City of Dublin Hospital by Mr. Henry Gray Croly, Senior Surgeon to the Institution. The case was originally fracture of the humerus at the surgical neck in a girl, aged about twenty years. The accident was caused by direct violence on the first occasion. A second fracture occurred from a fall, and a third time the bone gave way from pulling on a tight boot. Mr. Croly joined the fractured ends by wire, but expressed grave doubts about the result, inasmuch as the periosteum was detached for a considerable distance, and the fragments were wide apart. Acute necrosis set in and abscesses formed, and the girl's health was beginning to suffer. The amputation was completed in thirty-five seconds. The axillary vessel gave no trouble. Antiseptic spray and dressings it is almost needless to add were strictly carried out. The girl is doing well, the temperature this, the 5th day, being normal.

The recent specimen was exhibited at the Surgical Section of the Academy of Medicine on last Friday evening.

Medical Union Society.

ON Saturday last there was a good attendance of members at the rooms of the Medical Union Society, the occasion being a debate on "The Preliminary Training of Medical Students." The proceedings were opened by Mr. Morratt Baker, F.R.C.S., who occupied the chair, and introduced Dr. A. E. Sansom, F.R.C.P., who had consented to deliver an address as a preliminary to discussion. A long and well sustained debate ensued, in which numerous members of the Society engaged. Eventually a resolution, proposed by Dr. Sansom, advocating a standard of preliminary education for medical students equivalent to that required for an ordinary arts' degree at Oxford or Cambridge, was unanimously passed.

The Examinations of the Irish College of Surgeons.

THE examinations for the Licence of the Irish College of Surgeons will commence, for the first half, on the 2nd of April, and for the second half on the 20th. The first year's examinations under the new scheme of examination will be held in July. The Council issued last week to Registrars of Schools and Clinical Hospitals throughout Ireland a copy of the new schedule, by means of which all candidates for the College licence will, in future, be required to submit their certificates to the Inspection Committee. The schedule, in conformity with the certificate regulations promulgated by the College on the 29th of June, 1882, requires that the number of lectures in each course, and the number of the students' attendances shall be certified by the School or Hospital Registrar, and by the student himself.

Homes for Inebriates.

THE Association formed last year to found a Dalrymple Home for Inebriates held their first general meeting last week. The committee said they had failed, as yet, in attaining a site for the Home, but hoped soon to do so. The funds of the Association were represented by a Banker's balance of £600, and £1,100 promised. One donor, moreover, had promised £500 conditionally on nine other sums of the same amount being secured. The officers elected for the next year include Lord Shaftesbury as president, and numerous prelates and noblemen as vice-presidents.

Collegiate Combination.

THE scheme for a combined examination conducted by the Colleges of Physicians and Surgeons in London was last Thursday finally passed and accepted by the latter College, and remains now only to be formally ratified by the College of Physicians. If, however, rumour speaks correctly concerning the "improvement" thus provided, there is in store for future candidates at the English Colleges experiences which are likely to occasion much trouble and inconvenience. The conjunction over which so much care and time have been expended seems no more than a simple addition of one College to the other, for students aspiring to the qualification of either will have to pass all examinations at both, and pay for the privilege of increased burdens *thirty-five guineas*. We admit

this is not actually published at the time we write, but there is good reason to fear its truth; and if it be indeed the result of the joint committee's activity, then it will indeed, be a sorry indication of the fitness of corporations to manage their own affairs. After much preliminary flourishing, for the two most respectable licensing institutions to combine in multiplying the evils of the existing system seems a monstrous and wholly unexpected outcome of their labours. The whole profession will anxiously look for some immediate proof that their fears are not well founded.

Medical Society of London.

A GENERAL meeting of this Society was held on Monday, March 5th, 1883, when the election of the officers and Council took place with the following result:—*President*: Sir Joseph Fayrer, M.D., K.C.S.I., F.R.S. *Vice-Presidents*: J. Hughlings Jackson, M.D., F.R.S.; John Cawood Wordsworth; John Brunton, M.D.; Alfred Cooper. *Treasurer*: Alfred Wiltshire, M.D. *Librarian*: William Henry Allchin, M.B. *Honorary Secretaries*: Isambard Owen, M.D.; Alfred Pearce Gould. *Secretary for Foreign Correspondence*: Sir William Mac Cormac. *Council*: Henry Francis Baker; Samuel Benton; Sidney Coupland, M.D.; John Hamilton Craigie; Henry Radcliffe Crocker, M.D.; John Henry Drew; William Ewart, M.D.; James Kingston Fowler, M.D.; Heneage Gibbes, M.D.; David Henry Goodsall; George Lawson; Henry Morris; Francis Mason; Edmund Owen; Arthur Ernest Sansom, M.D.; Charles Brodie Sewell, M.D.; Thomas Gilbert Smith, M.D.; William Heath Strange, M.D.; William Johnson Walsham; C. Theodore Williams, M.D.

Royal Medical Benevolent Fund Society of Ireland.

WE regret to learn that Dr. Lynn, in consequence of advanced years has found it necessary to resign his appointment as Honorary Secretary for Armagh. The Central Committee adopted the following resolution:—

"That this Committee accept with much regret the resignation by Dr. Lynn, of the office of Honorary Secretary for Armagh, which he has filled greatly to the advantage of the Society for upwards of twenty years, and desire to convey to him the best thanks of the Committee for the great interest which he has ever taken in the Medical Benevolent Fund."

The Society was formed in Dublin by the late Dr. Kingsley in the year 1842, and the Armagh branch in the following year.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Birkenhead 17, Derby 18, Portsmouth, Edinburgh, Huddersfield, Leicester 19, Norwich, Brighton 20, London, Salford, Bristol 21, Oldham, Bolton, Leeds, Halifax 22, Birmingham, Nottingham 23, Bradford, Hull 24, Sunderland 25, Manchester 26, Preston, Sheffield 27, Wolverhampton 28, Glasgow, Plymouth, Newcastle-on-Tyne 29, Liverpool 30, Blackburn 31, Cardiff 33, Dublin 34.

Personation.

IN our issue for the 7th ult. we referred to a gross case of personation by a quack, who had falsely assumed the name of our colleague Dr. Archibald Hamilton Jacob, of Dublin, and fraudulently taken fees of divers of Her Majesty's subjects in and around London by pretending to be the said Dr. Jacob. The case was taken up by the Medical Alliance Association, which has done good service by the prosecution of quacks of this type. With the knowledge that a warrant was out for his arrest, this individual quickly made himself scarce, and it was only last week that he was brought up, convicted, and sent to prison for three months. More glaring evidence of the impudence of these quacks it would be difficult to imagine. The fellow, whose real name did not transpire, was previously a ship's cook, uneducated, and, of course, without any medical knowledge, except such as might be gleaned from the outside label of a bottle of patent medicine; yet, as will be seen on reference to the case reported in another column, patients presented themselves and paid him fees on the strength of Dr. Jacob's name and reputation. Whilst our *confrère* is entitled to the sympathy of the profession for having his name thus dragged in the mire, good may nevertheless result if the quack fraternity are thus taught that whatever name or disguise they assume they will be promptly repressed by the Society which so energetically prosecuted the case in question.

HIS Excellency the Governor of Gibraltar has appointed John Henry Bryant, L.R.C.P.Ed., to act as Inspector of Health at Gibraltar, in the room of Surgeon-General Smith, M.D., C.B.

MR. WILLIAM BERRY, M.R.C.S. Eng., L.R.C.P. & S. Ed., House Surgeon to the Royal Albert Edward Infirmary, has been added to the list of magistrates for the Borough of Wigan.

DR. FANCOURT BARNES, Assistant Physician to the Royal Maternity Charity, was last week elected Physician thereto, vice Dr. Hall Davis, who has filled that post, and has been elected Consulting Physician after forty years of valued services.

IT is officially announced that Miss Edith Shove, M.B., London, has been appointed Medical Superintendent of the Female Staff at the London General Post Office. This is, we believe, the first appointment of a lady medical to any Government post.

AT the last meeting of Congregation of the University of Cambridge the following gentlemen were appointed members of the Board of Electors to the Professorship of Zoology and Comparative Anatomy:—Professor Flower; Mr. H. N. Moseley, Linacre Professor, Oxford; Dr. Michael Foster, Trinity; Professor Huxley; Mr. J. W. Clark, Trinity; Mr. F. Darwin, Trinity; Professor Humphry; Mr. D. M'Alister, St. John's.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the

latest official returns, as follow:—Calcutta 42, Bombay 36, Madras 37, Paris 27, Geneva 28, Amsterdam 33, Rotterdam 26, The Hague 22, Copenhagen 26, Stockholm 24, Christiania 17, St. Petersburg 38, Berlin 23, Hamburg 26, Dresden 23, Breslau 34, Munich 34, Vienna 32, Prague 38, Buda-Pesth 30, Trieste 40, Rome 22, Turin 30, Venice 30, Lisbon 30, New York 25, Brooklyn 21, Philadelphia 21, Baltimore 28.

The Erichsen Testimonial.

On Saturday last a crowded meeting was held in the Botanic Theatre of University College, under the presidency of Mr. John Marshall, F.R.S., when the testimonial subscribed for by the friends and admirers of Mr. Erichsen was formally handed over to the keeping of University College. The memorial is in the form of a bust of Mr. Erichsen, and a sum of money remaining over from the sum collected, after its cost had been defrayed, was handed over to Mr. Erichsen to employ as he thought fit, the following resolution to that effect having been proposed by Sir Henry Thompson, and carried unanimously:—"That the surplus beyond the amount required for payment of the bust be now offered to Mr. Erichsen, as a personal gift from the body of the subscribers, to be devoted by him to any purpose which he himself might select." Mr. Erichsen was received with unbounded enthusiasm, and after speaking with evident emotion of his long connection with University College Hospital, he observed that he felt it a proud honour to have his own bust in the same gallery with such men of medical and surgical science as Liston, Sharpey, Turner, Potter, and others who had gone before him. In reference to the surplus, he proposed to invest it so as to produce an annual trial of skill in operative surgery, with a permanent prize of certain value to that student who proved himself the most efficient in the class of practical operative surgery.

The Profession at the Levee.

By command of Her Majesty the Queen a levée was held on Monday afternoon, at St. James's Palace, by His Royal Highness the Prince of Wales, when the following members of the profession connected with the Medical Departments of the Army and Navy had the honour of presentation:—Surgeon-Major Ralfe Lane, Surgeon-Major Waghorn, Staff-Surgeon J. C. B. Maclean, Staff-Surgeon J. Neeson Stone, and Surgeons Briggs, Gilborne, Gipps, and Kellard. All these presentations were made on return from active service abroad, or on promotion, either by H.R.H. the Duke of Cambridge or the Director-General of the Army or Navy Medical Departments.

By the will of Mr. George Tierney, late of 61 Pall Mall, Fellow of Merton College, Oxford, who died on February 8th, St. George's Hospital, Charing Cross Hospital, Westminster Hospital, the Royal Seaman's Hospital, University College Hospital, Middlesex Hospital, and the Hospital for Consumption and Diseases of the Chest, Brompton, each receive the handsome legacy of £5,000. He also bequeaths "£200 to his good friend Dr. Quain," and he desires that that gentleman shall receive and

enjoy any rights and privileges attaching to the legacies to the said hospitals.

FROM diseases of the zymotic class the death-rates were again below the average, throughout the United Kingdom last week the highest registered were—From whooping-cough, 2.1 in Plymouth, and 2.7 in Hull; from scarlet fever, 1.1 in Sheffield, and 1.9 in Leeds; and from fever, 1.7 in Sunderland, 1.8 in Liverpool, and 2.4 in Blackburn. The 29 deaths from diphtheria included 13 in London, 6 in Glasgow, 2 in Portsmouth, 2 in Liverpool, and 2 in Sunderland. Small-pox caused 7 deaths in London, 3 in Newcastle-upon-Tyne, and 1 in Birmingham. The excessive mortality in Dublin was principally confined to aged persons and to deaths in public institutions.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

AURAL SURGERY AT THE EDINBURGH ROYAL INFIRMARY.—The managers of the Infirmary having decided to create the post of Aural Surgeon to the Infirmary, Dr. Kirk Duncanson has become a candidate for the appointment. Dr. Duncanson, who is a lecturer in the Medical School, has paid considerable attention to aural surgery, and his appointment will give general satisfaction to the profession here.

DR. EADIE AND THE FACULTY OF PHYSICIANS AND SURGEONS APROPOS OF THE CHLOROFORM QUESTION.—Hitherto we always understood that the monthly meetings of the Faculty were of a *private* nature, but at the meeting on the 5th inst., either a reporter must have been present, or the speech made by Dr. Eadie which appeared in the *Glasgow Herald* of Wednesday, the 7th inst., must have been furnished to that paper. The speech is too long for transference to our columns, and, moreover, it is probable that those interested in the dispute have already seen it in the lay newspapers. It consists of a vindication of Dr. Eadie's conduct in giving an adverse vote on the chloroform question, and his reasons for refusing to explain said vote when demanded by Dr. Eben Watson.

A CROWDED INFIRMARY.—The number of patients at present in the Aberdeen Infirmary is somewhat in excess of the number for which accommodation is provided. The result is that the patients have had to be accommodated in the Hall where the quarterly meetings of the institution are wont to be held.

THE GLASGOW DEATH-RATE.—For the week ending with Saturday, the 3rd inst., the deaths in Glasgow were at the rate of 29 per 1,000, against 33 for the preceding week, and 25, 27, and 27 for the preceding periods of 1882, 1881, and 1880 respectively.

FACULTY OF PHYSICIANS AND SURGEONS.—At the monthly meeting of the Faculty, held on the 5th inst., it was intimated by Dr. Finlayson, Honorary Librarian, that Mr. William J. Mackenzie had presented to the Faculty the entire medical library collected by his father, the late Dr. William Mackenzie, the distinguished oculist. On the motion of Dr. Finlayson a vote of thanks was accorded to Mr. Mackenzie for his valuable gift.

UNIVERSITY OF ABERDEEN.—Professor Brasier has been unanimously chosen as Dean of the Medical Faculty in the University of Aberdeen, *vice* Professor Francis Ogston, resigned.

THE FIFE JAMIESON MEMORIAL.—The memorial fund to perpetuate the memory of the late Dr. Fife Jamieson having been closed, a sum of about £220 was found to be available; a portion of this sum has been devoted to the erection, within Old Machar Cathedral, of a very handsome memorial tablet of black and white marble. The balance of the fund has been invested for the purpose of providing a gold medal to be competed for annually by students in anatomy in the Aberdeen University—in which subject it will be remembered, Dr. Jamieson was assistant to Professor Struthers. The competition for the first award of the medal takes place during the current month.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 3rd inst., was 85, and the death-rate 19 per 1,000. There were 18 deaths under 1 year, and 28 above sixty, of which 7 were above 80 years of age. Diseases of the chest accounted for 46 deaths, and zymotic causes for 8, of which 2 were due to fever. The intimations of these diseases for the week amounted to 7, scarlatina 36, and measles 33.

EPIDEMIC OF MEASLES AT HOGGANFIELD, GLASGOW.—Measles of an exceedingly severe form has been epidemic here for a considerable time. It is worthy of note that, although this trouble gained an entrance into most households in the district, not a single case falls to be reported among the 400 youthful inmates of the Mossbank Industrial School, which is within the affected area.

MR. McEWEN AND THE GLASGOW ROYAL INFIRMARY DIRECTORS.—A private meeting of the Directors of the Glasgow Royal Infirmary was held on the 10th inst. in the City Chambers of the Institution. The meeting had been called at the request of a committee of the directors, with the object of considering what course should be adopted with reference to the resignation of Mr. Wm. McEwen, Chairman of the Committee of Management, referred to in our last issue. There was a large attendance, and a most animated discussion took place on various proposals that were made. Ultimately it was agreed to let Mr. McEwen's resignation lie on the table until another meeting, the question in dispute to be in the meantime considered, and a report thereon prepared by a committee of the Board of Management, this committee to consist of the gentlemen who were recently appointed to deal with the matter, with several names added. It is not easy to divine what may be the result of the present unfortunate contest. In the meantime we think it creditable to the staff of the institution that hitherto they have taken no notice of the one-sided and ill-advised articles which appeared in the daily papers.

Medico-Legal Intelligence.

CONVICTION OF A QUACK DOCTOR.

On Thursday last, a man giving the name of Hamilton Archibald Jacob was charged on a warrant before Mr. Ellison, at the Lambeth Police Court, with unlawfully taking the name, title, and description of a registered medical practitioner.

Mr. Pridham appeared to prosecute on behalf of the Medical Alliance Association.

George Spring, an engineer, living in Flaxman Road, said he knew the defendant. On the 28th of January he saw the defendant's name on a brass plate in front of a house in Asylum Road. The plate bore the inscription, "H. A. Jacob, Surgeon, &c." The defendant had attended the sister of witness as a medical man. In December he asked the defendant if he was the Dr. Jacob of Dublin, and he said he was. He told him he thought that scarcely possible, as he believed Dr. Jacob was still practising in Dublin. The defen-

dant was paid several times for his services, and always asked for his fee when attending.

Mr. Robert Hill Hodson, surgeon, practising at Peckham, said some months ago the prisoner was at his house, and described himself as Archibald Hamilton Jacob, of Dublin. Witness asked him if he was the celebrated ophthalmic surgeon, and he said he was. Witness asked him to look at one of his eyes and tell him what was the matter with it. He made an examination, and then said the witness could not see with one eye. This was not true, and after some further conversation the brother of witness said the defendant was a quack, and kicked him out of the place.

Detective Viney, of the P division, said that when he took the prisoner on a warrant he found on him some cards, upon which were printed the words, "H. A. Jacob, Physician and Surgeon; consumption, asthma, paralysis, palsy, sciatica, gout, lumbago, and neuralgia perfectly cured by H. A. Jacob, 25 Asylum Road."

Mr. Albert Alfred Tindall said he was manager of the English department of the *Medical Press and Circular*; Dr. Archibald Hamilton Jacob was the editor of the Irish department of the same paper in Dublin. The witness had known Dr. Jacob intimately for 18 years. The defendant was not Dr. Jacob or a bit like him, nor had Dr. Jacob ever left Dublin for practice elsewhere.

Mr. Pridham said he had other witnesses present who would prove that the defendant had attended their children as a physician and surgeon. He pressed for the fullest penalties, as it was most important that such a system should be put down.

The defendant had nothing to plead in answer to the charge, except that he was not now practising.

The magistrate said such a dangerous system as that carried on by the prisoner must be stopped, and he ordered him to pay a fine of £20, and £5 5s. costs, or in default to undergo three months' imprisonment.

The prisoner, who said he was without money or goods, was removed in custody.

Medico-Parliamentary.

HOUSE OF LORDS.

MEDICAL ACTS AMENDMENT BILL.

LORD CARLINGFORD has introduced a Bill for Consolidating the Law relating to Medical Practitioners. The Bill was read a first time.

HOUSE OF COMMONS.

POISONOUS MEDICINES.

In reply to Mr. WARTON, Mr. MUNDELLA stated that it was intended to bring in a Bill further to regulate the sale of poisons, and that the measure would apply to patent medicines of a poisonous nature.

POISONOUS MANUFACTURES.

In reply to Mr. BROADHURST, Sir W. HARCOURT stated that he thought the facts contained in the memorial of the cotton operatives which had been laid before him as to the dangerous effects of oversizing upon the operatives were such as to justify a medical inquiry, which would be at once instituted by the Government.

Obituary.

M. SEDILLOT.

THIS illustrious French surgeon died on the 28th of January in his 79th year, at Sainte Menchould, where he has been living in retirement for some years. Born in 1804, he became a Member of the Medical Faculty at Paris in 1824, and entered the Army Medical Service the same year. From that time till 1841 he attended the military colleges and the Faculty at Paris. He was made surgeon-major in 1824, and was attached to the hospital at Metz the following year. After this he returned to Val-de-Grâce, and when compelled for the place of assistant-anatomist, gave several lectures on normal and pathological anatomy, and took his physician's degree in 1829. Two years later he left with Malmignac for Poland to attend the insurgents there, and was in 1831

appointed, together with Malgaigne, Larrey, Lenoir, and Huguier, as a Member of the Assembly. He became first "side-major," then demonstrator at Val-de-Grâce, and after his surgeon-major and professor in the above school. Failing to obtain the Chair of Clinical Surgery, he went to Algiers, and again being disappointed in a competition for the Chair of Operative Medicine, he at last succeeded in obtaining the Professorship of External Pathology and Clinical Surgery at the Strasburg Faculty of Medicine. Being afterwards appointed surgeon to the military hospital there, medical inspector, &c., he remained a long time at that place. After the cession of Strasburg to the Germans he was offered the position of Professor at the new Faculty of Nancy, but he only accepted the honorary title. His most notable contributions to surgical science had reference to the employment of dynamometers in reduction of dislocations, the creation of gastric fistulae, which he effected first in the human subject in 1849, flap amputations, coxæ-femoral disarticulations, surgical anaesthesia, preservation of the periosteum in resections, staphyloraphy, rhinoplasty, urethrotomy. He maintained also, with much ability, the theory of phlebitis in parent infection, and his work on this subject is one of our classics. Whatever opinion may be in future entertained respecting the works of Sédillot, their value was justly prized by his contemporaries. Perhaps his erudition may be reproached as being factitious, but that was the usual fault of erudition fifty years ago, and to form a fair judgment one must go back to the epoch when Sédillot wrote his treatise on operative medicine, a period when competition was so ardent, and when, in the publication of teaching books, everyone seemed to have for his object not so much to do better than others as to overtop them. The funeral of M. Sédillot took place on February 22; deputations from the Institute, the Academy of Medicine, and from Val-de-Grâce and Nancy rendered the last homage to his memory.

Literature.

ON FAILURE OF BRAIN-POWER. (a)

THE aim of the author is to "elucidate the nature" of the very obscure conditions known as asthenia of the nerve centres, and establish the superiority of galvanisation of the brain as a means of treatment. This he proposes to do within forty-five small pages, five of which are taken up by the symptomatology of other disorders. A royal road to knowledge, truly, this pamphlet, if it fulfils the promises thus raised. But alas! turning for information concerning the cerebellum we find that all the author has to say about it occupies eight lines and a half, which we shall quote *in extenso* as giving the best illustration of the spirit of the whole book:—"This organ was formerly believed to be the seat of the reproductive faculty and desire, but we look upon it now as the centre for the equilibration of the body. The most constant symptom of tumour of the cerebellum is giddiness, and where this symptom is present in asthenic patients without disease of the cerebellum, the semicircular canal, or the stomach, we may conclude that it is owing to failure of power in the cerebellum." Does Dr. Althaus really believe that this kind of writing will "serve to advance an important department of medicine?" Had it not been that we knew him already as the writer of several valuable and laborious volumes, we should at once have put down the book as one intended *ad usum laici*. Having, by a process of reasoning similar to the one first exemplified, localised the protean symptoms of cerebral asthenia in the various portions of the brain, the author proceeds to elucidate their pathological substratum; and, for this purpose, calls to his aid and amplifies the old analogy between electrical and nervous "resistance." He thinks that his arbitrary explanation of asthenia, not by a diminution of the energy, but by an increase in that "resistance" of nerve cells "opens up a new vista for the explanation of numerous nervous disorders," whilst to us it appears like the substitution of one vague conception for another. Superficial analogies of this sort have more frequently retarded than assisted the progress of scientific thought. They may occasionally be of the same use as diagrams are for teaching purposes, but

(a) "On Failure of Brain-Power." By J. Althaus, M.D., M.R.C.P., London. 8vo. Pp. 60.

become mere *ignes fatui* in the fields of actual research. A number of cases are adduced to illustrate the therapeutical value of galvanism in cerebral asthenia. We shall not follow the author upon a ground which he has made so peculiarly his own. We do not pretend to pass any judgment upon his results. But this we would say: if Dr. Althaus wished to convince, not the public, but the medical profession, of the value of his method, he could not have failed more conspicuously than he has done. He has injured his own cause by his injudicious advocacy, a cause, we repeat, against which we have not the slightest prejudice, nay, in favour of which there is fair *prima facie* evidence. Dr. Althaus concludes his pamphlet with the announcement of a sequel on "the various forms of spinal debility." Before he commits himself to this course he will do well to ponder over the hidden meaning of the line "*facilis descensus Avernii*."

FIRST AID TO THE INJURED. (a)

THIS admirable little volume is intended as a text-book for the numerous associations for the relief of the sick which are everywhere springing up. Here they are intended for domestic purposes, but on the Continent there is no concealing that they look very much to warlike eventualities. All the various accidents, injuries, and emergencies are clearly described, and with entire absence of technicalities. In every instance the reader is told what to do pending the arrival of regular medical aid, and is placed in the position of aiding, not superseding, the medical profession. In cases of drowning the author leans to Silvester's, and not to Marshall Hall's mode of inducing artificial respiration—remarking that one man can accomplish the former. Illustrations are introduced here and in the other places requisite.

We should be wanting did we not offer our humble tribute to the exalted lady who has so well fulfilled the office of translator. The work is most admirably done, and the volume has none of the stiffness of a translation, but all the freshness of original work, all the crabbed technicalities of the German language being smoothed away. We look upon this action of H.R.H. as an extension of the courtesy and consideration which her Royal mother has always graciously extended towards the medical profession.

FOODS: THEIR COMPOSITION AND ANALYSES. (b)

SINCE the passing of the acts dealing with the adulteration of foods and drugs, the demand for correct and reliable chemical processes by which adulteration can be detected has become more and more imperative. Several methods of procedure have, from time to time, been published in the journals by independent workers, but these have been deprived of their value by the manner in which they appeared. The older works on the subject too, dealt with methods of adulteration, crude when compared with the ingenious sophistication of the present day. To supply the want to which we have referred, Mr. W. Blyth, in the volume now before us, has admirably succeeded. To the chemist and medical practitioner, the work is alike important, although, of course, chiefly addressed to the former. Apart from the practical details with which the book deals, there are chapters in which subjects of general interest are fully discussed, for instance, we have chapters on the history of adulteration in England, France, and Germany, containing much curious information. We also have an account of English legislation with regard to the adulteration of food. A description of some of the apparatus required by the analyst, and a chapter on the use of the microscope, complete what may be called the general portion of the book. Each article of food is then taken separately, and the processes for the detection of adulteration given with great clearness and precision. The chapter on milk is especially deserving of notice, and appears to us to leave little, if anything, to be said on the subject, in fact, milk, cream, butter, and cheese are treated of in Part iv., absorbing 119

(a) "First Aid to the Injured." Five Ambulance Lectures by Dr. Frederick Esamarch, Professor of Surgery to the University of Kiel. Translated from the German by H.R.H. the Princess Christian. London: Smith & Elder. Crown 8vo, pp. 100.

(b) "Foods: Their Composition and Analyses." A Manual for the Use of Analytical Chemists and others. By Alexander Wynter Blyth M.R.C.S., F.C.S. London: Charles Griffin and Co.

pages of the book. A chapter on water analysis, added by request to this edition, renders the book especially useful to the medical officer of health. In conclusion, we can honestly recommend the book both to analysts and medical practitioners, each will find the information he requires reliable, in fact, it is a book that must be possessed by the one, and should be read by the other, and kept as a work of reference.

QUAIN'S ELEMENTS OF ANATOMY. (a)

QUAIN'S Anatomy is a text-book of which British anatomists are justly proud. It is, therefore, with some anxiety that each new edition is received, lest the usual standard of excellence may not be maintained. In the eighth edition there was indeed a marked falling off in the first volume; every here and there were traces of careless reproduction. In the present instance, this volume has been remodelled by Mr. Thane, the energetic professor of anatomy in the University College of London, and we congratulate him most heartily upon the success which has attended his efforts. Never, perhaps, has the first volume of Quain's Anatomy appeared to better advantage. The revision has been evidently effected with very great care and judgment, and the new matter added has been well selected. The old woodcuts are also rendered quite gay, and much more instructive, by the colouring of the veins and arteries. The improvements in this volume which specially deserve notice, are (1) a very concise abstract of craniology; (2) a more complete account of the fascia of the pelvis; and (3) an important and valuable chapter upon superficial and topographical anatomy. We look forward to the time when the chapter on osteology will be extended. The brief description of the bones, which is given in Quain's Anatomy, is the chief cause of other inferior works upon anatomy being so frequently preferred by the medical student. With "Quain," a special work on osteology is also required, and students very naturally dislike the necessity of reading from two text-books.

The second volume has gained considerably in bulk, fully 100 pages has been added. It is devoted to Histology, Splanchnology, and Embryology, and its revision has been effected, as before, by Dr. Allen Thomson and Mr. Schäfer. This volume has come to give character to the whole work, and in the three departments of anatomy which it embraces, it stands pre-eminent as a student's text-book. In these subjects, there has been a great advance in the last few years, and the alterations which have been thus rendered necessary, are very numerous; everywhere indeed we meet with changes, and in every case the result is most satisfactory.

As presented to us in its present form, Quain's Anatomy more than holds its position, and we recommend it strongly to all students of medicine.

NEALE'S DIGEST. (b)

THOSE who have used the "Medical Digest" prepared for the New Sydenham Society by Dr. Neale will hail the reappearance of the work, brought up to more recent date, with unalloyed satisfaction. The issue of a second edition of so invaluable an aid to medical labour and research of every description could not but become a matter of necessity. Dr. Neale, however, has done much to deserve a renewal of the gratitude his work originally aroused by the completeness with which he has made the additions called for by lapse of time. It needs but a small acquaintance with the "Digest" to enable a full appreciation of its great utility to be arrived at; and we selfishly trust that the immense labours undertaken by the author in its production may be sufficiently rewarded to encourage him to give us periodically an extended form of the work. It consists mainly of retrospect references to the medical journals, dating as far back as 1837, and to a writer upon any special subject it supplies a need in no other way to be obtained. What would be a labour of days, or even weeks, is reduced to one of minutes. But it is not by writers only that this

work will be found useful. The physician, surgeon, and general practitioner who has not the periodical ready at hand to look over may still have his memory awakened by reading the heads or descriptions placed before him in the "Digest," for we find many diseases taken through first as to their pathology, the causes, diagnosis, and treatment, all employed remedies being mentioned by name, with an explanation which, though intended for reference, actually embodies the essentials of the paper or article referred to. So thoroughly, moreover, has Dr. Neale accomplished an almost illimitable task, that all but the very latest subjects discussed in medical journals are referred to by him. In this respect particularly the volume assumes an encyclopædic character, without the attendant inconveniences surrounding the usual encyclopædias. By a system of reduction, and by the constant employment of judiciously-chosen contractions, the author of the "Digest" has succeeded in compressing an amount of information truly gigantic within the limits of a not too cumbersome volume; and in such an excellent fashion is the work achieved, that no person will fail to find in it the essential details—at least, relating to treatment particularly—which he may be in quest of.

To form an adequate conception of the work is, however, after all, only possible by those who have actually used it, and found their labours immeasurably lightened thereby. To them, as to us, it will be patent that Dr. Neale has given to the world of medicine what is among the most invaluable of all works of reference.

EXERCISES IN PHYSIOLOGY. (a)

DR. BURDON SANDERSON has published for general use by students of physiology a collection of exercises which have been found to work well at University College. They serve as a guide to the practical physiology courses formerly given under Prof. Sanderson with the assistance of Mr. Page, B.Sc., Mr. W. North, B.A., and Dr. A. Walker. Included in the work are exercises relating to the physiology of muscle and nerve, with demonstrations of the use of apparatus concerned, and on chemical physiology. Under this last head the series of analytical tests usually carried out are arranged in order under the various substances, animal and vegetable, met with in this department of chemistry, including urine and blood. A considerable number of laboratory demonstrations in connection with starch and its derivatives; albumen, globulin, &c.; digestion, urine, muscle, and bile, are appended. By means of these the advanced student is afforded directions for practical pursuit of this important part of his education, which will be found of infinite service to intending candidates at university medical examinations. The work, indeed, is of a nature that adapts it more particularly to this class of readers; to them it will be invaluable.

GUIDE TO THE L.S.A. EXAMINATIONS. (b)

IN preparing a guide to the popular "Hall" examinations, written on lines very similar to those followed by Mr. Gant in his well known guide to the examinations of the Royal College of Surgeons, Mr. Dawson has supplied a want experienced by a very considerable number of students. This little work contains all the information necessary to enable candidates for the L.S.A. diploma to comprehend every detail connected with the qualification, and many useful hints are added which cannot fail to be of service to intending licentiates. Very complete lists of the questions actually set at past examinations are given, and the book concludes with a number of notes on medicine, midwifery, and medical jurisprudence. Many of these last possess somewhat the nature of "tips," it must be said, but on this account they will probably be found even more valuable than mere formal lessons. The "Guide" is, altogether, a very useful little manual.

(a) "Quain's Elements of Anatomy." Edited by Allen Thomson, M.D., F.R.S., &c.; E. A. Schäfer, F.R.S.; and Geo. D. Thane. Ninth edition. London: Longmans, Green and Co. 1882.

(b) "The Medical Digest." By Richard Neale, M.D. London: Ledger, Smith, and Co. 1882.

(a) "Practical Exercises in Physiology." By J. Burdon Sanderson M.D., F.R.S., &c. London: H. K. Lewis. 1882.

(b) "Guide to the L.S.A. Examinations." A Guide to the Examinations of the Apothecaries' Hall, London. By W. E. Dawson, L.S.A.L., &c. London: Baillière, Tindall, and Cox. 1882.

Novelties.

POCKET MEDICAL EMERGENCY CASE.

By T. FREDERICK PRABER, M.D.

THE case described by the above title is made of ebony, and in shape resembles a large drawing pencil. At one end is a special and neatly-packed hypodermic syringe. The other end is made up of a series of compartments (fitted on somewhat like the pieces of an object-glass belonging to a microscope), containing discs and perles of certain drugs likely to be required on an emergency. The chief substances provided for are *morphia*, to relieve sudden and acute pain; *apomorphia*, to induce immediate vomiting; *nitrite of amyl* of perles for allaying spasm of muscles in angina, asthma, &c.; *ergotine*, for hemorrhage; and ether in perles, as a rapid stimulant for syncope, &c. Each compartment is distinctly marked with the name and the quantity of each drug it contains. The whole forms a most compact case, which can be very readily carried in the pocket, and provides for almost every emergency not requiring surgical instruments. It has been made for me by Messrs. Arnold and Sons, of London.

CARBOLISED SOAP SHEETS.

THE habit of carrying a private supply of soap while travelling is one very common among English people, and especially so with those who have once experienced the misery of endeavouring to cleanse the skin after the Continental standard, which, to judge from the absence of soap in toilet arrangements abroad, demands the removal of surface dirt with the assistance of water alone. The spirit of compassion would seem to have been excited on our behalf in this respect, even among the very authors of our discomfort, for a recent invention designed to remedy it in future emanates from the fertile genius of a Viennese patentee named Buczowski. This gentleman has been struck by the happy notion of manufacturing "soap sheets," which consist of fibres of tissue paper thickly loaded on either side with a plaster of soap. These sheets are then bound up in books of a hundred leaves each, and half a dozen such volumes may easily be carried in the space occupied by the usual cake of brown Windsor in an ordinary dressing case. Carbolic soap sheets have also been introduced, and these, or any variety, plain, scented, &c., &c., can be now readily obtained at a small expense. One sheet suffices for an ordinary wash, and the use of the novelty is attended with no kind of unpleasantness or drawback. Travellers have good reasons to feel thankful for so useful and timely an invention.

AUTOMATIC POCKET INDUCTION APPARATUS.

DR. THEODOR STEIN, the distinguished physiologist and electrician, of Frankfort-on-the-Maine, has recently invented a very convenient and extremely portable apparatus for the medicinal employment of Faradaic electricity, an illustration of which we give here. The apparatus consists of two handles which contain both battery and coil. In using it, we unscrew the lid GG, fig. 1, and take out the carbon (p) and zinc (z). We then, by means of a small porcelain pot fill the hard rubber case A to 1-3rd with the exciting solution to be hereafter described. We then screw on the lid and connect the cable H at c, b, and K by sticking the wires into their indicated holes, so that the wire with one notch is inserted into the stud c, the wire with two notches into the stud b, and the wire with three notches into the lower stud K. The wires of the other end of the cable are in like

manner inserted into the corresponding studs d, e, f. (In the instrument the studs are numbered 1, 2, 3, to correspond with the notches on the wires.) As soon as this is done, the secondary (stronger) stream is set up, and a buzzing noise is heard in the handle, fig. 2, which contains the coils. If it is desired to employ the primary stream, to move the three-notched wire from the stud f (3) into the second hole in stud e (2), so that this stud contains both the two and three-notched wires. In order to increase the strength of the stream, the damper M must be pulled up. The further it is pulled out, the stronger is the stream. Brass cylinders may be screwed on to the ends of the handles for electro-gymnastic exercises. For faradisation of the body these are to be replaced by electrodes covered with flannel, which is to be moistened in warm water. When using the apparatus, the small rubber screw a, fig. 1, must be unscrewed to a small extent to allow the escape of the gases formed during the electrical action. The developing fluid is made with 80 grammes of bichromate of potash, 100 grammes of sulphuric acid, 1,000 grammes (1 litre) of water. The extreme handiness and great power of this electrical apparatus will, no doubt, recommend it to those practitioners who make use of faradaic currents in their practice. Dr. Stein informs us that the apparatus may be obtained in London from Krohne and Sesemann, and Meyer and Meltzer. It is not expensive.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

C. A. V.—The title "Dr." can be legally used only by such persons as have obtained a degree in medicine, and degrees are conferred by universities only. It is permissible by courtesy that the public style members of the profession "Dr.;" but it would be contrary both to law and etiquette for any gentleman who does not possess the degree to sign himself "Dr." or "M.D." It is quite true that in America a medical qualification, whencesoever obtained, confers the title M.D.; but American institutions are, in this respect at least, still unaturalised in Great Britain, and we venture to think they are very likely to remain so for a considerable time to come.

EXPERTANT.—The prospects of legislation in favour of medical reform are said to be considerable by the quidnuncs who "suppose they know" what is in the womb of time. We confess, however, to a feeling of doubt as to the passage of an Act to amend the profession

during the present year, although it has been introduced and read a first time in the House of Lords.

IGNOSCO.—"Red precipitate" is the common name for the red oxide of mercury— HgO , and not for the *iodide* of the same colour. It is prepared by heating dry mercuric nitrate with metallic mercury. It is given in the form of pill when prescribed for internal use, in half-grain doses; but it is not usually so to employ the drug.

A. J. P.—The next International Medical Congress will be held at Copenhagen, under the presidency of Prof. Panum. We are not aware that any arrangements have yet been made with a view to enabling visitors from this country to travel to the Congress at reduced fares.

DR. MURRAY.—We regret that the crowded state of our columns precludes acceptance of the proposed articles.

MR. THOMAS.—Your question is not a proper one to be put in these columns. It is more fitted to appear in one of our general scientific contemporaries, the readers of which will doubtless appreciate the reference it contains.

MR. CORNISH.—Opposition to tobacco-smoking is often based on ignorance of physiological laws; and the tirade you submit is in no respect better or worse than the rubbish usually advanced against the use of "the weed." We quite agree with you that it is unworthy of consideration. Unquestionably smoking is injurious when indulged in by children and boys, or when even adults pursue the practice to excess.

MUSCULAR REPARTER.—It is related in a recent number of *Chambers's Journal* of an examiner who was getting impatient of the density of a candidate, that on one occasion, having failed to elicit satisfactory replies from a student regarding the muscular arrangement of the arm and leg, he somewhat brusquely said:—"Now, sir, perhaps you could tell me the names of the muscles I would put in action were I to kick you!" "Certainly, sir," replied the candidate; "you would put in motion the flexors and extensors of my arms, for I should use them to knock you down!" The writer is silent, and perhaps wisely so, concerning the fate of this particular student.

MR. CARSTONE.—The most suitable book from which to gain a knowledge of the most recent advances in histology and anatomy is undoubtedly the last edition of "Quain's Anatomy." For practical physiology, Harris and Power's "Manual" is the most suitable guide you can adopt.

M. D.—The matter was referred to in our issues for July and August, 1881. Please adopt some more distinctive cognomen in future communications.

W. G. L.—Mr. Jennings has a work on the subject in the press, which will be published very shortly.

A HATER OF SHAMS.—We feel certain that if Her Royal Highness knew the character of the institution to which it is announced she has given her patronage, it would be at once withdrawn. It is hardly within our province to carry out your suggestion, but we will see what can be done, as, like you, we are "haters of shams."

LONGEVITY—REMARKABLE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Those interested in "Remarkable Cases of Longevity" may find a goodly array by consulting section 2-6 of the "Medical Digest." Among others there noted are those of 137 Russian peasants who died at the ages ranging from 100 years to 147; also of a half-bred, San Salvador, who, in 1873, had attained the age of 180 years, a statement, however, not allowed to pass unchallenged.

I am, Sir, yours truly,

RICHARD NEALE, M.D. Lond.

MR. A. E. F.—It is not necessary that a candidate should be a Fellow of either College; the only qualification necessary for the appointment is thorough efficiency, and perhaps a little private influence.

MR. WILSON.—The relief given by the Society is necessarily confined to the widows and orphans of those medical men who have been subscribing members. We fear the case you are interested in is not eligible if the father had not been sufficiently provident during his life to subscribe to the Society.

F. R. M. (Edinburgh) should advertise his wants in one or other of the medical journals. We do not keep a "registry office for assistants."

SIR THOMAS WATSON'S WILL.

SOME surprise has been expressed at the magnitude of the will of Sir Thos. Watson, M.D., recently proven by his executors, Sir Thomas having virtually retired from practice many years since. The value of the personal estate amounts to upwards of £164,000. To his daughter, Miss Margaret Catherine Watson, in addition to his furniture and effects, the testator gives certain stocks amounting to over £26,000, and an annuity of £800. All his real estate and the residue of the personality, excepting some pictures, books, and other articles specifically bequeathed to his daughter-in-law, and to his friend Dr. George Johnson, he leaves to his son Sir Arthur Townley Watson.

MR. CHAS. LUNN (Birmingham) will receive a private note.

SURGEON (Bruff).—You can be admitted a member of the Irish Medical Association by sending your name to Dr. Glick, 8 Dawson Street, Dublin, with name of a member to propose you. You will be kept informed by the periodical reports of Council of what is being done for the advantage of the profession by the Association; and every one who benefits by the labours of the Council ought to join the Association. The subscription is 10s. 6d. a year.

MR. E. COTTERELL (Bicester).—We shall be glad to find space for the paper.

MEETINGS OF THE SOCIETIES, COLLEGE LECTURES, &c.

WEDNESDAY, MARCH 14TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m., Professor Flower, On the Anatomy of the Horse and its Allies.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m., Lumleian Lecture: Dr. A. B. Garrod, On Uric Acid, in its relation to Renal Calculi and Gravel.

HUNTERIAN SOCIETY.—7.30 p.m., Council.—8 p.m., Mr. Tatham, On Malformed Heart.—Dr. Warner, The Advantages of Antiseptic Precautions in Draining Dropsical Legs.

ROYAL MICROSCOPICAL SOCIETY.—8 p.m., Dr. C. T. Hudson, On a Batch of New Floscules.

THURSDAY, MARCH 15TH.

ROYAL INSTITUTION.—3 p.m., Professor Dewar, On the Spectroscopy and its Applications.

HARVEIAN SOCIETY.—8.30 p.m., Clinical Evening. Several Cases and Specimens of Interest will be exhibited.

FRIDAY, MARCH 16TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m., Professor Flower, On the Anatomy of the Horse and its Allies.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m., Lumleian Lecture: Dr. A. B. Garrod, On Uric Acid, in its relation to Renal Calculi and Gravel.

ROYAL INSTITUTION.—8 p.m., Professor Tyndall, On Thoughts on Radiation, Theoretical and Practical.

ACADEMY OF MEDICINE IN IRELAND.—Medical Section.—Living Specimen: Dr. M'Donnell, A Case of Hammer-cramp.—Specimens exhibited by Card: Dr. C. J. Nixon, Intussusception of the Death Struggle.—Dr. J. W. Moore, Disease of the Aortic Valves, with Compensatory Mitral Regurgitation.—Dr. Hawtrey Benson, Abscess in Wall of Bladder which pointed externally.—Papers: Dr. W. Frazer, "Bleeders," and Sudden Death from Cerebral Hemorrhage in such cases.—Dr. R. M'Donnell, Case of Hammer-cramp, with observations (the patient will be exhibited).

Vacancies.

Athlone Union, Brideswell Dispensary District.—Medical Officer. Salary, £140, and usual fees. Election, March 22nd.

Cambridge County Lunatic Asylum.—Resident Medical Superintendent. Salary, £500, with furnished residence, &c. Applications to be sent to the Clerk to the Visitors before March 16th.

Great Northern Hospital, Caledonian Road, London, N.—House Surgeon. Salary, 60 guineas, with board and lodging in the hospital. Applications to be sent to the Secretary on or before March 22nd.

Henley Union.—Medical Officer. Salary, £103. Applications to be sent to the Clerk to the Guardians before March 21st.

Nottingham Dispensary.—Resident Surgeon. Salary, £200, with apartments, &c. Election, April 2nd.

Appointments.

CLIPPINGDALE, S. D., M.D., F.R.C.S., Surgeon to the Kensington Dispensary.

DICINSON, W. H., M.D. Cantab., F.R.C.P.L., Consulting Physician to the Kensington Dispensary.

EARLE, L. M., M.D., C.M. Ed., Medical Officer for the Fourth and Fifth Districts of the Royston Union.

HEWSELEY, F., M.B. E.C.S., Assistant Medical Superintendent to the Royal India Asylum, Ealing.

PHILIP, T., M.B. Ed., House Surgeon to the Greenock Infirmary.

PROTHERO, E., M.R.C.S., Medical Officer for the Amlock District of the Anglesey Union.

REID, W., M.B., C.M., Resident Medical Officer to the Kensington Dispensary.

SANDFORD, A. W., M.D., M.Ch., Surgeon to the Cork Ophthalmic and Aural Hospital.

TORRENS, J. L., Medical Officer to the Connor Dispensary, Antrim Union.

Births.

CUNNINGHAM.—March 6th, at Edinburgh, the wife of Surgeon-General J. P. Cunningham, A.M.D. (retired), of a daughter.

FISHER.—March 7th, at West Walks, Dorchester, the wife of F. Bazley Fisher, M.R.C.S., L.R.C.P., of a daughter.

HILL.—March 2nd, at Turcoolah, Chumparun, Bengal, the wife of Dr. James H. G. Hill, of a son.

NEALE.—March 8th, the wife of William Neale, L.R.C.P., Mountmellick, of a daughter.

THOMPSON.—Feb. 24th, at Blackrock, the wife of E. C. Thompson, M.B., of Omagh, of a son.

Marriages.

GILBERT—IRWIN.—March 8th, at Castle Caldwell Church, W. F. Gilbert, L.R.C.S.I., L.K.Q.C.P.I., to Elizabeth Annie, eldest daughter of Wm. Irwin, M.D., Belleek.

Deaths.

ARNOTTE.—March 4th, at St. Stephen's Crescent, Westbourne Park, W., James Arnotte, M.D., formerly of St. Helena, aged 85.

DUNBAR.—March 6th, suddenly, at 2 The Cedars, Clapham Common, Georgina Fairlie, wife of Surgeon-General J. A. Dunbar, M.D., H.M. Bengal Army, aged 60.

GARDNER.—Feb. 28th, at his residence, Worthing, Sebastian Claude Thomas Gardner, M.R.C.S.E., aged 48.

GOODCHILD.—Feb. 25th, at Heathfield House, Ealing, Francis Goodchild, M.B. Lond., aged 28.

JACOBS.—March 8th, at 3 Russell Road, Kensington, Henry Jacobs, F.R.C.S., aged 63.

PILKINGTON.—March 7th, at his residence, Clayton-le-Moors, William H. Pilkington, M.D., J.P., aged 62.

PONDER.—Feb. 28th, at his residence, Hayes Cottage, Dulwich Road, Brixton, William Ponder, M.R.C.S., aged 74.

ROBERTSON.—March 8th, at Mount Albion House, Ramagata, Sophia, relict of Dr. John Robertson, Inspector-General of Hospitals.

ON

STERILITY IN WOMAN.

Delivered in the Royal College of Physicians, London, February, 1883.

By J. MATTHEWS DUNCAN, M.D., F.R.C.P.L.,
Physician-Accoucheur and Lecturer on Midwifery at
St. Bartholomew's Hospital, &c.

LECTURE II.—PART II.

ITS THEORY OR CAUSATION.

FINALLY, Shorthouse has pointed out in mares the close alliance between sterility, abortion, and that kind of excessive fertility which is demonstrated by twinning. I quote the examples which he gives in the *Sporting Times* for Dec. 12th, 1874; and, as adding to the force of the evidence, it is to be remembered that in the mare twinning is a far rarer event than in woman and the cow: in these it occurs about once in 80 pregnancies; in the mare it is said to be only once in 400:—

Miserrima, barren in 1855, 1858, 1867, 1870, and 1871; slipped foal in 1856, 1859, and 1863; had dead twins in 1860 and 1862.

Caricature, barren in 1852, 1854, 1855, 1861, 1867, and 1871; had twins in 1856 and 1863; slipped foal in 1868.

Legendemain, barren in 1852, 1859, 1864, and 1866; slipped foal in 1849; slipped twins in 1856, 1860, and 1862.

Crystal, barren in 1858, 1860, and 1865; in 1866 slipped twins.

Slander, barren in 1851, 1854, 1864, 1865, and 1866; slipped twins in 1857.

Thimbling, barren to two horses in 1867; slipped twins in 1869.

Zoe, barren in 1865, 1866, 1867, 1868, 1869, 1870, and 1871; slipped foal in 1860.

No. 1, barren in 1865 and 1868; slipped foal in 1867.

No. 5, barren in 1856, 1858, 1860, 1864, and 1866; slipped foals in 1862 and 1868.

No. 7, barren in 1857 and 1860; had twins in 1853.

No. 8, barren in 1867; had twins in 1861.

No. 9, barren in 1858, 1860, 1864, and 1867; had twins in 1868.

No. 10, barren in 1858, 1860, and 1864; had twins in 1861.

No. 11, barren in 1856, 1863, and 1864; slipped foals in 1859 and 1865.

I know no observations worth quoting as to the special sterility of male lower animals, and the subject requires much further investigation. It is not quite a new subject, for it is popularly believed that certain stallions are often inefficient; and accordingly breeders, in their advertisements, take care to add to the other qualifications of a named horse that he is a "sure getter."

In woman sterility varies in amount according to the age at marriage. This is shown by the table which I compiled from the data of Edinburgh and Glasgow in 1855. (See Table IX.) It is evident that this table gives only an approach to the truth, for in its second column there is an excess of children over marriages that cannot have been. Incongruity of this kind is not only accounted for, but to be expected, from the manner in which the table is made up. The numbers of marriages in Edinburgh and Glasgow in 1855 at different ages of the wives are compared with the numbers of first living children born in the same year to wives married at the same ages in that year or previously, and the number of sterile wives is got by subtracting the latter figures from the former. The comparison is of the first births of one year with the marriages of the same year, while they were mostly the result of the marriages of the former year, and the table is consequently imperfect. It must be remembered that this table, like the others from the same source, gives the title of first children to the first-born living, excluding the dead from the reckoning, another manifest source of error. But there can be no doubt, I think, of the conclusion as to age which is derivable from it—that women married under twenty years of age have much more sterility than women married from twenty to twenty-four inclusive, and that the sterility of marriages before twenty is less than the sterility of marriages after twenty-four, and that of marriages after twenty-four the sterility increases with the age at marriage. A nearly

similar conclusion is derivable from the Statistics of Provi-
dence published by Snow.

TABLE IX.
Showing the Variations of Sterility according to the Age at Marriage.

Ages of wives at marriage	15-19	20-24	25-29	30-34	35-39	40-44	45-49	50, &c.	Total.
Number of wives ...	700	1,885	1,120	402	205	110	46	29	4,447
First children ...	649	1,905	809	251	96	10	2	...	3,722
Sterile wives ...	51	...	311	151	109	100	44	29	725
Percentage sterile	7.3	...	27.7	37.5	53.2	90.9	95.6	100.0	16.3
Percentage sterile: 1 in ...	13.72	...	3.60	2.66	1.88	1.10	1.05	1.00	6.13

TABLE X.
Showing the Initial Fecundity of Women of Different Ages within the First Two Years of Marriage.

Ages of wives newly married	15-19	20-24	25-29	30-34	35-39	40-44	45-49	50-54	55-59	60-64	65-69	Total.
Number of wives newly married ...	700	1,885	1,120	402	205	110	46	30	6	4,447
Number of wives mothers, bearing in 1855, and within two years of marriage ...	306	1,661	849	253	84	17	2	3,172
Proportion of latter to former is 1 in ...	2.3	1.1	1.3	1.5	2.4	6.4	23.0	1.4
Or percentage ...	48.71	90.51	75.80	62.93	40.97	15.45	4.35	71.33

yet the conclusion that it is so, at least in the very young, appears to be inevitable. For if the women married under twenty are more sterile than those married at twenty to twenty-four, and are also more relatively sterile so far as delay of childbearing shows this quality, then, if the marriages of the very young—that is, of those under twenty—had been delayed till the next quinquennial, they would in greater numbers have shown fertility and shown it also more quickly. Now, as the only difference known between those of twenty to twenty-four and those younger is age at marriage, we may reasonably conclude that premature marriage was the cause of the sterility. There may be some analogous injurious influence of too long delayed marriage upon the elderly, and the delay of commencing childbearing may point to it; but we cannot say of them, as we do of the youngest married, that if they had still further delayed marriage they would have had more chance of being mothers! Some further reference to this evil influence of marriage, and attempt at explanation, will be found in the discussion on sexual pleasure.

TABLE XI.

Showing the Initial Fecundity of Women under Twenty Years of Age within the First Two Years of Marriage.

Ages of wives newly married	16	17	18	19
No. of wives newly married...	48	108	225	314
No. of wives mothers within two years of marriage ...	4	27	98	177
Proportion of latter to former is 1 in ...	10.7	4.0	2.3	1.8
Proportion after correction for immaturity is 1 in ...	7.7	3.3	2.1	1.7
Or percentage ...	12.90	30.00	46.44	57.84

TABLE XII.

Showing the Mortality of Children Born in Marriages formed at Different Ages.

Years elapsed since birth of first child.	Mortality per cent. of the children born to marriages formed at ages—			
	16-20.	21-25.	26-30.	31-35.
10	36.87	37.69	37.89	35.48
20	47.44	43.10	44.36	16.67
30	53.03	49.89	48.53	64.29
40	63.12	57.14	68.00	50.00

I might here adduce evidence of the influence of age which is found in the weight and length of the children produced, the length and weight rising with the age of the mother to its climax in the children born to mothers between the ages of twenty and twenty-nine inclusive, and then again falling as the age of the mother increases above twenty-nine. This is a matter tested by too delicate variations of length and weight to be, as yet, quite relied on, and great authorities have indeed contested its truth, Hecker, for instance, alleging that the measurements increase with the age of the mother in a direct sort of proportion. But I have Aristotle on my side. "Premature conjunctions," says he, "produce imperfect offspring, females rather than males, and these feeble in make and short of stature. That this happens in the human race," he adds, "as well as other animals, is visible in the puny inhabitants of countries where early marriages prevail." The general tenour of the evidence is, indeed, very strong, in showing a concurrence of sterility, monstrosity, feebleness, and smallness, and on that account I still hold that diminished length and weight of children accompany the diminished fertility of the premature and post-mature women.

It is a matter of regret that we can present no demonstration of the influence of age on fecundity founded on the frequency of abortions and of ill-formed children. But we approach near to such evidence, and may guess what it would yield when we present the facts, scanty though they be, as to rearing of children and as to idiocy. Table XII,

The relative sterility of women at different ages is in part shown by their slowness to become mothers, or the length of interval between marriage and childbearing; and this is found to tally with the sterility according to age which I have just stated. I give another Edinburgh and Glasgow table embodying the facts bearing on this. (See Table X.) Those married below twenty years of age were longer in married life before becoming mothers than those married between twenty and twenty-four inclusive. These latter showed the highest fecundity and quickness to commence bearing children. Those again married after twenty-four were slower than their predecessors, and the slowness increased with every additional quinquennial after that of twenty to twenty-four.

In the quinquennial preceding twenty I can give for each single year the increasing delay of childbearing as age decreased. Table XI., from the Edinburgh and Glasgow data, shows this relative sterility of early ages.

At this point of the inquiry as to the influence of age I interpolate an argument as to the influence of marriage or cohabitation in causing sterility. Although it seems at first sight absurd to rank marriage among the causes of sterility,

derived from the data obtained by the Statistical Society in St George's-in-the-East, is the only body of facts as to the rearing of children born of mothers of different ages that I know of. It shows a diminished amount of rearing of children of the sterile ages. The sterility or weakness of reproduction by mothers of sixteen to twenty years of age is shown by the failures in rearing, and increased failures in rearing appear again as the sterile ages above twenty-five are entered on, the failures to rear increasing with the age of the mothers just as sterility increases at the same ages.

TABLE XIII. (from Arthur Mitchell).

Showing the Comparative Frequency of Births of Idiots, and of all Births, in First and Subsequent Pregnancies.

Number of pregnancy.	Percentage of all births.	Percentage of idiot births.
First ...	22.8	33.0
Second ...	17.7	18.8
Third ...	15.5	13.6
Fourth ...	12.1	2.4
Fifth ...	9.4	2.4
Sixth ...	7.4	2.4
Seventh ...	5.2	7.0
Eighth ...	3.9	3.5
Ninth ...	2.6	2.4
Tenth ...	1.3	7.0
Eleventh9	3.5

TABLE XIV. (from Langdon Down).

Showing the Comparative Frequency of Births of Idiots, and of all Births, in First and Subsequent Pregnancies.

Number of pregnancy.	Percentage of all births.	Percentage of idiot births.

Twelfth4	1
Thirteenth2	3
Fourteenth06	1

TABLE XV. (from Arthur Mitchell).

Showing a Comparative Percentage of the Children Born at Different Ages of Mothers to all Children Born, and of the Idiots Born at Different Ages of Mothers to all Idiots Born.

Age	20-21 ..	25-29 ..	30-34 ..	35-39 ..	40-44 ..	45-49
Percentage of all children ..	22.62	30.99	23.61	14.76	5.15	0.58
Percentage of idiots ..	25.38	25.83	10.53	10.53	23.53	3.58

We suppose that, from the time of their birth, the children of these observations were tended with the same care or desire of the mothers to act fairly by them; and that we must look to some cause of the failure to rear in the reproductive arrangements. Now, here we include the nourishment of the child among the reproductive processes, while in our other studies of sterility we stop at its birth, or, if we proceed further, we consider only conditions presumably already established or commenced at the time of birth, such as idiocy. The child is naturally fed upon its mother's milk, and the feeding is an extra-uterine continuation of the previously otherwise conducted nutrition of the fetus. Nursing is part of the reproductive process. The failure to rear may be a result of imperfection of the fetus, now a child, or it may be the result of the imperfection of the mother as a nurse. I know no method of disentangling the results of these two causes, but the potency of imperfect nursing is undoubted. It is a universally recognised rule in the selection of wet nurses that very young or elderly mothers are to be avoided.

Imbeciles and idiots may be so from original or innate causes, sometimes called developmental, or from injury or other accidental causes. The undoubted frequency of acci-

dents at births or other injuries as causing imbecility and idiocy introduces an element which should be subtracted with a view to the ascertainment of the influence of the mother's age in the production of the mental weakness; but, although in individual cases the two kinds, the developmental and accidental, may with much assurance be distinguished, I know no way of doing so in the statistics to be adduced. Authors on this subject, especially Little, attach great importance to the resuscitation of the stillborn as an accidental cause of idiocy, and it may be so; but I am disposed to attribute the necessity for resuscitation partly to the feebleness of the imbecile child produced. Among Langdon Down's 2,000 cases, 400, or 20 per cent., were born in a state of suspended animation, and 40 per cent. of these 400 were first children. At all events, it will not be disputed that the great majority of idiots and imbeciles are so from innate or developmental, not accidental, causes acting during or after birth.

Among Mitchell's 443 idiots and imbeciles 138 were first-born; among Wilbar's 675 there were 191 first born; among 100 of Beach's, 20; among 2,000 of Down's, 480. Or among 3,218, 829, or about 26 per cent., were first born, and presumptively born of young mothers.

"Among 443 idiots and imbeciles consecutively examined (says Mitchell), I found 138 first born, or 31.1 per cent.; and 89 last born, or 20.1 per cent. When it was known, however, that almost every sixth idiot in Scotland was illegitimate (663 idiots and imbeciles, giving 108 illegitimate or 17.1 per cent.), it was thought that an element of disturbance was probably thus introduced into the foregoing figures which might affect their value. The great majority of illegitimate children are known to be first born and only children; while not a few of them are last born, though the last of a small number of pregnancies—say of two or three. It was therefore thought desirable that a fresh series of observations should be made, excluding the illegitimate, and dealing only with those born in marriage. It was also thought well to confine these observations to those cases in which not more than one idiot occurred in a family, and in which the idiocy was noticed very soon after birth—that is, in which it was probably congenital. Further, no cases were accepted but those in which the mothers at the time of the inquiry had passed the age of childbearing, though some of them, I think, were widows before that age was reached. All these restrictions made it difficult to obtain a large series of observations, and account for their number not exceeding 85—44 males and 41 females. I sent my results in detail to Dr. Matthews Duncan, who kindly drew up for me the two tables embodying the facts in a way which makes their teaching apparent." (See Table XIII.) "This table is read in this way: Of all the children born in Edinburgh and Glasgow in 1855, 22.8 per cent. were first pregnancies; while of the 85 idiots, 33 per cent. were first pregnancies, and so on. What the table appears to teach is briefly this—that idiocy is more likely to occur among first and latest (seventh to eleventh) pregnancies than among others. This is substantially the same thing as was taught by the first inquiry, which included 443 cases, and in which all that was asked was whether the patient was first born or last born."

Similar evidence is derivable from the data given by Langdon Down, but in regard to them we have not the same assurance of the circumstances of the collections as is given by Mitchell in regard to his. Down's data are given in Table XIV.

Fortunately Mitchell gives the age of the mother at the time of the birth of the idiot, and the result is very striking. Down does not give the age of the mother in his collection, but considering the excess of primiparity and the very large proportional number of pregnancies of high figure among them, we can have no doubt they would yield a like result.

"The same eighty-five cases," continues Mitchell, "are used in Table XV. which were used in Table XIII. This table is read thus:—Of all the children born in Edinburgh and Glasgow in 1855, 22.6 per cent. were born of mothers whose ages were from twenty to twenty-four years, while of the eighty-five idiots 25.8 per cent. were born of mothers of corresponding ages, and so on. What we learn from the table is this: that mothers under twenty-four years of age and above thirty-five are those more specially liable to have idiocy in their children."

Several times I have been told by men of experience that

an old bitch often ends her career of breeding by a dead and premature pup. Whitehead regards those pregnancies which occur near the termination of the fruitful period in women as being the most commonly unsuccessful, and Arthur Mitchell has connected the occurrence of idiocy in a child to the circumstance of its being the last born of its mother. "That in the mother," he remarks, "which leads to the miscarriage may lead also to the idiocy, and the only connection may be one through a common cause. It frequently happens," he adds, "that between the birth of the idiot and that of the child which precedes or follows, an interval occurs which is much longer than usual, or that after the birth of the idiot permanent sterility appears. Again, when the idiot is born eighteen or twenty-four months after the preceding child, but when for six or seven years thereafter no impregnation occurs, he thought there was reason to suspect that the imperfection in reproductive power, which showed itself in the idiot, had merely another and fuller expression in the subsequent barrenness. And so also when permanent sterility follows. In many cases indications of barrenness preceded the birth of the idiot, and became permanent thereafter."

We have alluded to prevalent opinions that the last born of a woman is specially liable to be a miscarriage, or a weak child, or an idiot, and female rather than male, and have shown that these opinions have considerable support from facts. We have also spoken of the only-child sterility, the mothers being in Ansell's collection at the high mean age of thirty-one. Now, in addition, there is some, though imperfect, evidence that such children, especially if female, are not merely illustrations of one-child fertility or only-child sterility, but are also the last of their race. They represent a family's last effort at continuation of its line. Girls in such a position are often heiresses, though not certainly single children, and this circumstance has enabled Galton to follow up their history and to show their infertility. I know several remarkable cases of single children of this kind, feeble, rich, childless, the last of their race; but a collection of cases forms stronger evidence than any scattered good examples. Speaking of marriages of heiresses as peculiarly unprolific, Galton remarks: "We might, indeed, have expected that an heiress, who is the sole issue of a marriage, would not be so fertile as a woman who has many brothers and sisters. Comparative infertility (he adds), must be hereditary in the same way as other physical attributes, and I am assured it is so in the case of the domestic animals." In addition to other strong evidence of the same kind, Galton found, in a partial search through the peerage, a total of fourteen heiress-marriages among seventy peers, resulting, he says, in eight instances of absolute sterility, and in two instances of only one son. "I tried the question from another side," he continues, "by taking the marriages of the last peers and comparing the numbers of the children when the mother was an heiress with those when she was not. I took precautions to exclude from the latter all cases where the mother was a co-heiress, or the father an only son. Also, since heiresses are not so very common, I sometimes went back two or three generations for an instance of an heiress-marriage. In this way I took fifty cases of each. I give them below, having first doubled the actual results, in order to turn them into percentages:—

TABLE XVI. (from Galton.)
Showing the Infertility of Heiresses.

Number of sons to each marriage.	One hundred marriages of each description.	
	Number of cases in which the mother was an heiress.	Number of cases in which the mother was not an heiress.
0	22	2
1	16	10
2	22	14
3	22	34
4	10	20
5	6	8
6	2	8
7	0	4
Above	0	0
—	100	100

"I find that among the wives of peers, 100 who are heiresses have 208 sons and 206 daughters, 100 who are not heiresses have 336 sons and 284 daughters. The latter shows how exceedingly precarious must be the line of a descent from an heiress. . . . One-fifth of the heiresses have no male children at all; a full third have not more than one child; three-fifths have not more than two."

ON THE RELATION OF MICRO-ORGANISMS TO TUBERCULOSIS.

Abstract of Report presented to the Association for the Advancement of Medicine by Research, 1st February, 1888.

By W. WATSON CHEYNE, M.B., F.R.C.S.,
Assistant-Surgeon to King's College Hospital, &c.

A VISIT was paid to Prof. Toussaint, of Toulouse, and to Dr. Koch at Berlin, with a view of seeing their methods of experimentation, and the results which they had obtained. Various experiments were seen, and a quantity of material was brought back to England for more detailed examination. The result of the visits and a full account of the observations made will be found in the complete report which will be published in the April number of the *Practitioner*.

It was thought advisable in the first instance to repeat some of the experiments which have led observers, more especially in this country, to object to the view of the specific origin of tuberculosis, and to hold that in rodents at least any irritation might produce that disease. The present series of experiments were performed under the best hygienic conditions, with complete isolation of the animals from each other, and thorough disinfection of the instruments employed. In six cases sets of various kinds were introduced both subcutaneously and into the anterior chamber of the eye; in ten vaccine lymph, both from the calf and from man was employed; in three pyemic pus was injected (1) into the eye, (2) subcutaneously, and (3) into the abdominal cavity; and in six various materials, (cork, tubercle hardened in alcohol, and worsted thread), were introduced into the abdominal cavity. None of these twenty-five animals became tuberculous. Some experiments are also cited in the report in which wounds in rodents have been stitched up with cotton thread, and others in which abscesses have been produced in various ways, but in none of these cases did tuberculosis ensue. In explanation of the former results it is pointed out that at the time the early experiments on this subject were made the communicability of tubercle by mediate contagion was not recognised, and as the precautions necessary for disinfection of instruments had not at that time been made out, the channels for the introduction of specific micro-organism were left unguarded.

Two tubes of serum containing micrococci were obtained from Toussaint, who holds that micrococci are the cause of the disease. Toussaint obtains these organisms by inoculation of flasks containing serum, or a fusion of rabbit with the blood of tuberculous animals, and he has in some cases succeeded in producing tuberculosis by the injection of these cultivations into other animals. The material obtained from M. Toussaint was injected into three rabbits, two guinea-pigs, one cat, and one mouse, and of these seven animals six were under observation for a sufficient length of time for the development at least of a local tuberculosis. In no instance did the tuberculosis ensue. (In all the experiments detailed in the report, inoculation was made into the anterior chamber of the eye, whenever this was practicable syringes purified by heat were employed for the purpose.) Cultivations of these micrococci were also made and injected into nine rabbits and three guinea-pigs. Of these four rabbits and three guinea-pigs were under observation for a considerable time without the development of tuberculosis in any case. The total result is that thirteen animals were inoculated with the micrococci with which Toussaint works, and obtained from Toussaint himself, and in no case did tuberculosis occur.

A number of tuberculous organs from animals experimented on by M. Toussaint were also obtained, some of the animals having become tuberculous after the injection of the micro-coccal fluid. Careful examination of these organs has shown the presence, often in large numbers, of the tubercle bacillus described by Dr. Koch, but no micrococci have been

found. The conclusion arrived at is that the micrococci described by Prof. Toussaint are not the cause of tuberculosis. One of the possible explanations of the results, which should not be left out of account, is the following:—Prof. Toussaint trusted greatly to carbonic acid as a disinfecting agent for the purification of the instruments employed in inoculation. This antiseptic though effectual for the destruction of the ordinary forms of micro-organisms, as evidenced by the satisfactory results obtained from its use in aseptic surgery, has been shown to be ineffectual against the spores of bacilli, unless it acts for a long time. The bacillus of tubercle apparently produces spores, and there is no reason to suppose that these are less resistant than those of bacillus anthracis, and other bacilli. An experiment is given which shows that a saturated watery solution of carbolic acid, even though it acts as long as fifteen minutes, is not sufficient to arrest the development of the tubercle bacilli. Therefore, to wash a syringe with carbolic acid is not such a certain means of disinfection in this particular instance as was formerly supposed.

Experiments were also made with cultivations obtained from Dr. Koch. Twelve animals were inoculated with these organisms, chiefly into the anterior chamber of the eye, and all of them became tuberculous, and that more rapidly than after the inoculation of tuberculous material. The tubercles produced in these cases were infective, and caused tuberculosis in other animals. On examination of tuberculous material Koch's tubercle bacilli are always found, though in varying numbers. They are most numerous in bovine tuberculosis, and least numerous in human tuberculosis. About eighty organs of tuberculous animals, and thirty-six cases of human tuberculosis were examined, and in all of these, without exception, tubercle bacilli were found. The inoculation of these bacilli is more rapid and more certain in its effect than the inoculation of tuberculous material from any source, and this seems only explicable on the supposition that in the cultivations of these bacilli, the virus of the disease is present in a more or less pure state, and in large amounts. Various facts are pointed out leading to the conclusion that in these bacilli we have the virus of the acute tuberculosis caused in the lower animals by the inoculation of tuberculous material.

In applying the facts obtained from experiments on animals to the pathology of tuberculous diseases in man, it is pointed out that all that has as yet been absolutely proved is that a variety of materials in man which we class together as tuberculous, produce acute tuberculosis when inoculated into rabbits, guinea-pigs, and other animals, and that result is only due to the tubercle bacilli in the material inoculated. It therefore remains for inquiry, what relation these bacilli bear to the morbid processes in man in which they are found?

Acute miliary tuberculosis in man, resembles in every respect in histological structure, in tendencies, and in the presence of bacilli, the disease produced in the lower animals by the inoculation of tuberculous material, and there can be little doubt that the cause of both diseases is the same, viz., the tubercle bacillus. It is, however, much more difficult to understand the relation of these organisms to the localised tuberculosis processes in man (phthisis, scrofulous diseases of glands, joints, &c.). Phthisis is alone considered in the present report, and with a view of making clear the conception which the author has formed as to the relation of bacilli to this disease the following facts are brought forward, which he has observed as to the mode of distribution of these organisms in the tissue, and their relation to its histological elements.

Two distinct structures have been described as tubercles in the lungs of rodents, viz., nodules of lymphatic tissue in close proximity to the vessels and bronchi, and nodules which are largely made up of epithelioid cells. If a case of commencing artificial tuberculosis be examined, it will be found that bacilli are only found in the latter nodules; indeed, it is rare, even in the later stages, to find them in the former, and in that case epithelioid cells will be found as well. The bacillus being the cause of this disease, the nodules containing epithelioid cells are alone tubercles. Further, on careful investigation of these nodules, it will be found that bacilli are only present in the epithelioid cells themselves. In making this statement, only young tubercles, and those in which the bacilli are present in moderate numbers, are referred to. Where there are enormous masses of bacilli: or where there has been confluence of tubercles

forming a largish tubercular deposit, some bacilli may be found in the outer part of the mass, but the great majority of them occupy the epithelioid tissue. When the bacilli are few in number, one need only look for them in epithelioid cells. Around the epithelioid cells the tissue becomes inflamed and converted completely into granulation tissue. As the tubercle becomes older the epithelioid cells at the centre undergo caseous degeneration, and in this case the bacilli are present in the caseous mass, but are often best seen at its margin, when epithelioid cells still exist, and they may also be found penetrating into the inflammatory tissue. The giant cells of tubercle can be distinctly traced as originating from epithelioid cells, especially from epithelioid cells containing bacilli. As to the origin of these epithelioid cells in the lung, the great majority are undoubtedly derived from the alveolar epithelium. The bacilli escape from the blood vessels or lymphatics, and pass into the alveolar epithelium, where they grow, and cause multiplication of the epithelial cells until the alveolar becomes completely filled with them. In some instances, however, these cells are probably derived from the endothelium of blood and lymphatic vessels. In the case of the liver, the author thinks that they are frequently developed from liver cells, for the bacilli may be found in liver cells at the margin of commencing tubercles, and gradation in size and form can be traced between the liver cells and the epithelioid cells in the centre of the tubercle. The accumulation of the epithelium in the centre of the nodule leads to obliteration of the vessels around, and to fusion of neighbouring nodules.

With regard to phthisis, the two extremes, the rapid phthisis or caseous pneumonia, and the chronic or fibroid phthisis, are considered. In the rapid phthisis the alveoli are distended with caseous material, or in parts where the process is less advanced with epithelioid cells. Surrounding these the trabeculae are thickened and converted into granular tissue. Here the bacilli are found in moderate or considerable numbers in the caseous material, and epithelioid cells which fill the alveoli. By-and-bye the walls of adjacent alveoli disappear, and thus irregular cavities are formed containing caseous material, surrounded by epithelioid cells and inflammatory tissue. In this case the bacilli are most numerous, and sometimes in enormous masses at the free margin of the cheesy material; and they are also present, though not generally so numerous, in the epithelioid cells at the line of junction of the caseous mass with the surrounding tissue.

In fibroid phthisis the bacilli are, as a rule, extremely few, but here and there, if a cavity exists, or in the centre of a caseous mass, one may find them in considerable number. They may, though very rarely, be also found in the giant cells, which are generally pretty numerous among the fibrous tissue. As a rule, however, the bacilli are extremely few, but nevertheless, if a sufficient number of sections be carefully examined, a few will be found here and there at the margin of or in the caseous masses.

The foregoing facts seem to indicate that when the tubercle bacilli reach the alveolus of a lung which is in a suitable condition for their growth, they develop in the epithelial cells lining the alveolus. This alveolus becomes filled with cells, neighbouring alveoli become affected, and the same process goes on in them. The further result will depend on the number and growth of the bacilli, and on whether the patient is a good soil for their development. If they develop well, we have caseous pneumonia—if they grow slowly and with difficulty, we have fibroid phthisis. In the former case the alveoli become distended early with epithelioid cells, inflammation of the walls of the alveoli ensues, the epithelioid cells soon undergo caseous degeneration, and the pressure of the masses leads to atrophy or sloughing of the walls of the alveoli. Infection of neighbouring parts of the lung occurs, both by continuity and also by coughing-up and re-inhalation of the bacilli into other parts of the lung. In this rapid phthisis fibrous formation around the alveoli only takes place imperfectly, and the lung rapidly breaks down.

In the case of fibroid phthisis, the bacilli are few, and grow only with difficulty. Thus, fibrous formation occurs extensively, and giant cells are entangled in this fibrous tissue. In parts, however, the process may be more rapid, and thus cheesy masses are formed, which may lead to breaking down of the lung, and the formation of cavities.

In the report it is pointed out that on this view one explanation of the rarity of acute tuberculosis in connection with

phthisis, and of the presence of bacilli in spectrum even before physical signs are marked; while it is shown that this view is directly corroborated by the results obtained by Tappeiner in his inhalation experiments. Against the statement that phthisis is due to the tubercle bacilli might be urged the fact that the bacilli found in the lung after death are often very few in number. Among other facts brought forward with regard to this question, it is stated that very extensive tuberculous processes may be found in animals containing only few bacilli, and that in cases where bacilli alone were inoculated, and where it is certain that the bacillus was the only agent at work. With regard to the production of phthisis by the inhalation of dust of various kinds, it is pointed out that the foreign particles inhaled probably only prepare the lung for the reception of the bacilli, for in those cases also bacilli are found.

It has often been urged that the milk of tuberculous cows is infective. This may be the case when the mammary glands become tuberculous, and the mode in which the bacilli might get into the milk was well illustrated by the appearances found in a tuberculous kidney. There not only were bacilli present in the tubercular mass, but they were also found in large numbers in the epithelium of the kidney tubules, and in the interior of those tubules, both in the vicinity of the mass, and at some distance from it. The author has not yet investigated the subject of tuberculosis of the kidney, but from what he has seen, he thinks it probable that the epithelium of the tubule is the favourite seat of the bacilli in the kidney, just as the alveolar epithelium is in the lung. In that case bacilli would be present in the urine, not merely when there were marked tubercular masses in the kidney, but also when the disease was but slightly advanced. From analogy it is probable that the same is the case in the mammary glands, and bacilli might be present in the milk, even though the disease of the gland was not sufficiently advanced to be noticeable.

The staining solution employed was the Weigert-Ehrlich solution. The formula is, of a saturated watery solution of aniline 100 parts, of a saturated alcoholic solution of the basic aniline dye (methyl violet, gentian violet, fuchsin, &c.), eleven parts. Rapid staining is obtained by warming the solution. The specimens are then decoloured by immersion in nitric acid (one part to two of water) and stained in a suitable contrast dye. Very delicate sections are apt to be injured by the immersion in the nitric acid. In this case, after staining them in the Weigert-Ehrlich fuchsin solution, they may be washed in distilled water, immersed in alcohol for a moment, and then placed in the following contrast stain for one or two hours—Distilled water 100c.c., saturated alcoholic solution of methylin blue 20c.c., formic acid 10 minims. Wherever it is possible, however, Ehrlich's original method is recommended as being most rapid, most simple, and most satisfactory. By this method of staining, tubercle bacilli and leprosy bacilli remain red. The ova and the outer coat of some parasites also retain the red colour. Lichtheim has further stated that a micrococcus is frequently found in the fæces, which behaves in a similar manner to the tubercle bacillus.

ON THE SOLUTION OF THE ACTIONS OF REMEDIES, AND ON THE EXISTENCE OF NERVES OF INHIBITION AS EXEMPLIFIED BY THE ACTION OF SEDATIVES AND STIMULANTS.

By HUGH OWEN THOMAS, M.R.C.S.

(Continued from page 226.)

STIMULANTS.

DIFFERENCE of opinion prevails among therapeutic authorities as to whether certain drugs are endowed with sedative or stimulant properties. I shall only discuss the physiological effect and medicinal results that follow the use, either experimentally or therapeutically, of belladonna, this drug being selected by me in consequence of its value in the treatment of collapse.

By the term stimulant, I mean any matter which, after its introduction into or absorption by vital tissues, increases the activity of the condition antecedent to its introduction, without supplying the source of force for maintaining this increase of power or function—as food can do, i.e., a stimulant draws upon a reserve, which

can only be renewed by food. How therapeutists could have come to the conclusion that belladonna “possesses powerful anodyne and hypnotic properties”—“valuable anti-spasmodic” (a)—at the same time, “stimulant effect on the circulation”—“potent diuretic”—(a) is to me explicable only by the supposition that investigators have not made the physiological doses of belladonna the basis for their deduction in prescribing, and its toxic effects their basis for antidotal treatment.

If the symptoms which follow the physiological doses of belladonna are analysed, there always remains evidence of stimulation, and during its action the phenomenon of special affinity for certain structures is demonstrable, just as may be observed during the action of sedatives. Its effect in full physiological doses is to stimulate the radiating fibres of the iris by its special affinity for the sympathetic nerves, a branch of which aids in regulating the radiating muscle of the iris; but it may be said that this dilatation of the pupil by belladonna arises by the same mode of action as that which causes henbane to dilate the pupil. But this objection is inconsistent with the fact that the blood-vessels are diminished in calibre when under the influence of belladonna, from contraction of their muscular coat (necessarily a stimulative result), so that the pulse is less perceptible, but increased in tone, and the temperature becomes elevated. Further, the heart's action is always accelerated by belladonna from its primary affinity for and stimulating effect on the vagus nerve, which nerve this drug can protect from the collapse arising from mechanical irritation, (b) provided the use of the drug be such as not to approach too near the toxic area. During the action of belladonna the solid constituents of the liquids excreted are increased—another phase of stimulation. Hitherto no evidence has been made known which shows that belladonna retards life so long as its action does not overstep the area of physiological action—that of safety; and this area of perfect safety in a healthy subject is exceeded as soon as the drug, whether sedative or stimulant, begins to act beyond the structures which they have a primary or special affinity for. A remarkable discord of opinion exists in explanation of how belladonna can benefit in medical practice. With some of these views I coincide from most of them I must dissent. For instance—“Belladonna allays pain . . . the attendant spasm . . . it relaxes muscular fibre” . . . “in spasms the expulsive effects are moderated” . . . Belladonna relaxes the hollow viscera, and it is to this effect that we must attribute its antispasmodic as well as expulsive action.—Harley, Vegetable Neurotics, page 230. “By relieving spasm arising from irritation of the air tubes, gall ducts, and ureters in bladder, belladonna is serviceable.”—Royle, Materia Medica, page 495.

These quotations, all from recognised authorities, are a collection of contradictions. If it allays pain, relieves spasm, relaxes muscles, how can it possibly have an expulsive action?

“The constricting fibres of the intestines and of the ducts of glands are, in like manner, relaxed by belladonna, and of this we may take dilatation of the pupil as the outward sign. The dilatation of the pupil under the influence of belladonna is active and due to a stimulant effect on the sympathetic nerve.”—Royle, Materia Medica, page 493.

If the constricting fibres of the intestines are relaxed by belladonna, how the dilatation of the pupil by the same drug can be an active change I fail to perceive. This inconsistent teaching appears to have arisen from a misinterpretation of the mechanism of stimulation on the non-striated muscle. For instance, the effect that stimulation has upon the pupils, and upon the muscular coat of the blood-vessels. As an example—“The sympathetic has, it will be observed, an effect on the

(a) Harley, Vegetable Neurotics, page 241. Headland, Actions of Medicines, page 275. Royle, Materia Medica, page 493.
(b) Foster's Physiology, page 171.

iris the opposite of that which it exercises on the blood-vessels. When it is stimulated the pupils are dilated, while the blood-vessels are contracted."—Foster's Physiology, page 466. "It is probable that these fibres are under the control of the sympathetic system of nerves. If so, it must be observed that the sympathetic nerves have an effect upon the iris directly opposite to that which it exercises upon the blood-vessels, since when it is stimulated the pupils are dilated, while the blood-vessels are contracted."—Raney, Applied Anatomy of the Nervous System, page 133.

The sympathetic has not an opposite effect on the iris to what it has upon the blood-vessels. Stimulation of the sympathetic nerves excites the circular muscular coat of the blood-vessels to contract, and this contraction can only take place in the direction of diminishing the area of a circle. The iris being a radiating muscle, then, if stimulated through the sympathetic nerve, it can only contract in the direction of its largest circumference, as the iris is a radiating muscle attached at its greatest or external circumference, so that it can only contract in the direction of its outer circumference, its base of resistance, and so dilatation must occur when the radiating muscle of the iris is in action; theoretically, dilatation of the pupil corresponds to contraction in a blood-vessel, when either is under sympathetic stimulation. "Retention of urine is a frequent result of a full medicinal dose of belladonna."—Royle, *Materia Medica*, page 492.

In the above quotation we have another out of many errors in regard to the action of belladonna that can be found in standard works written on therapeutics; it is an example of the toxic action being selected as evidence of the medicinal result of a drug. Retention of urine is not a result that follows a medicinal dose of belladonna; but it may be urged, if it is not the result of either a physiological or medicinal dose of the drug, it is fair evidence that it relaxes the muscular coat of the bladder and points to a sedative effect. This I deny. It is excellent evidence that it is a stimulant, and this toxic effect of belladonna upon the bladder is quite consistent with its effect upon other structures, and in support of this contention my reasons are the following:—

If the anatomy of the nerve supply to the bladder be considered, it will be found that the upper part of the bladder is supplied from the hypogastric plexus of the sympathetic, while the spinal nerves can be traced directly to its neck and base. (a)

The most reliable authority on the action of the vegetable neurotics has conclusively established that large doses only have the effect of causing retention of urine, and I hold that causation of this act arises in this manner. As soon as a toxic dose of belladonna has crossed its area of physiological action (vagus and sympathetic), the store of nerve energy within this area upon which it has primarily drawn is much diminished, but further forward in the toxic area which includes the vagus, the sympathetic and spinal nerves, the store of energy within the spinal nerve is in full force, until this area is crossed and death supervenes. These toxic doses of belladonna, having exhausted the nerve supply of the body of the bladder, at a time when it is commencing to stimulate the base and neck, must necessarily give rise to retention of urine.

As regards the doses of atropia, it is my opinion that when administered by the subcutaneous method, any quantity exceeding 1-48th of a grain becomes a toxic dose, and that, provided the drug be of good quality, it is always advisable to commence with much less, say 1-60th, and increase gradually until the physiological effect is attained.

(To be continued.)

Clinical Records.

JERVIS STREET HOSPITAL.

Vesical Calculus, of which a No. 1 Catheter formed the Nucleus—Stricture—Albuminuria—Lithotomy.

Under the care of **AUSTIN MELDON, F.R.C.S.I., M.K.Q.C.P.I., M.R.I.A.**, Surgeon to Jervis Street Hospital.

J. St. L., *æt.* 30, married, no children, by occupation a clerk, was admitted into Jervis Street Hospital on June 20, 1881.

The previous history showed that he had suffered from severe stricture since 1871, and frequently during that time had had complete retention of urine. During the past six years a No. 1 was the largest instrument which could be passed into the bladder. Last January, while in Northampton, was relieved by the introduction of a No. 1 catheter, which was allowed to remain in the bladder while he walked home. On arriving there the instrument was not to be found. From that to the present date he has never been free from pain. Of late he sleeps little, and has completely lost his appetite.

On admission into hospital he presented the appearance of having suffered a great deal. His body was emaciated and features pinched, his pulse quick and feeble; the water, which caused great pain in passing, only came in drops. It required nearly an hour to enter the bladder. The urine became almost solid when heated. Even the smallest instrument would not pass beyond two inches from the orifice of the urethra, where it was arrested by a stricture.

After some days this was dilated so as to allow the introduction of a probe, which revealed the existence of a stony deposit. Some of this was removed by a urethral forceps, and some by means of a director; but as his symptoms were so urgent, it was decided to open the urethra in front of the bladder.

On the 20th of July Dr. Meldon performed the operation. The patient was placed in the lithotomy position, and the urethra opened through the perineum. This was rendered somewhat more difficult than usual by the fact that no staff could be passed down beyond the scrotal portion, and consequently there was little to guide the knife. A very considerable amount of deposit was removed, and the passage completely cleared. A sound was now introduced into the bladder, but no stone could be found. After the operation the patient improved very much. He slept well, his appetite returned, and he even gained flesh. Matters went on in this way for a couple of months, when symptoms of stone reappeared. A sound passed into the bladder at once revealed the presence of a calculus.

Dr. Meldon removed this by the lateral operation. The stone weighed one ounce, and had for a nucleus the catheter doubled up, and each turn or bend showing through the stone. The deposit previously removed from the urethra weighed nearly half an ounce.

The patient made a rapid recovery, and left the hospital about six weeks after the operation. He has since, however, died of well-marked Bright's disease.

Dr. Meldon, in his remarks to the students on the case, called their attention to the danger of leaving an instrument in the bladder without securing it carefully. He also mentioned that he always used Dr. McDonnell's triangular staff, which allows of a much larger one being introduced, and renders it almost impossible to lose your guide to the bladder. He had now used it in some thirteen cases, and would not now use any other staff.

SHEFFIELD FEVER HOSPITAL.

Treatment of Ulcers with Large and Slowly Separating Central Sloughs.

By **B. A. WHITELOGG, M.D.**, Resident Medical Officer

The following is, as far as I am aware, a new method of treating these ulcers, although possibly the same idea may have occurred to others as well as to myself. In these ulcers the slough frequently remains, as a hard, white mass, very slow and tedious in separating from the subjacent tissue. There being no possibility of healing whilst this mass remains, its rapid removal becomes a matter of some importance. Finding that the ordinary methods of treatment were slow in effecting separation of the slough, I was led to try the effect

(c) Quain's Anatomy, vol. II., page 426-7. Eighth Edition.

of pepsine as a dressing. I have now used it in some half-dozen cases, and with the most satisfactory results. Within a week it dissolves the slough, and leaves a granulating surface, very amenable to further treatment. My method of using it is to apply a lotion to the ulcer containing pepsine wine, mixed in varying strengths, but usually about half pepsine and half water, with a little tr. of lavender to improve its appearance.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND. THE PATHOLOGICAL SECTION.

The Pathological Section met on Friday, March 2nd, at the Royal College of Surgeons, the President of the Section in the Chair.

SPECIMENS EXHIBITED BY CARD.

Dr. QUINLAN—1. Bacillus anthracis in blood; 2. Bacillus anthracis in lung tissue.

Dr. TWEEDY—Brain from a case of acute hydrocephalus, with microscopic sections.

Dr. WARREN—Recurrent fibro-myxoma.

Dr. DUFFEY—Secondary carcinoma of the liver, with microscopic sections.

Dr. R. McDONNELL—Scirrhus of the male breast, with microscopic mountings, from a patient, æt. 29.

Mr. P. S. ABRAHAM read notes on

THE BLOOD-VESSELS OF NEW GROWTHS, WITH ESPECIAL REFERENCE TO THEIR ORIGIN IN GRANULATION TISSUE.

The blood-vessels which are seen in sections of tumours may be considered under two heads—(1) those belonging to the proper tissue of the part into which the neoplasm has infiltrated; and (2) those which have arisen anew and belong to the new growth itself. The former have become enveloped by the new invading tissue, which they afterwards, in greater or less part, supply. The latter are the vessels of circumscribed growth, and are either prolongations or sproutings from the vessels of the neighbouring tissue, or, formed apart, have been subsequently connected with them. The small arteries and veins which come under the first category are often distinctly modified by what appear to be inflammatory changes, and the proliferation of the cells of the coats may go on to such an extent in the case of the intestine that the lumen may become occluded. An extreme case of the vascular wall thickened and studded with an irregular cell-growth is seen in certain sections of leprosy tumour. The young blood-vessels of neoplasms in general do not always show any distinction of tunica; and sometimes, in a quickly-growing mass of cells, the walls of the vascular channels can scarcely be differentiated from the surrounding cell tissue. From the consideration of the sections of granulation tissue, which had formed in sponges placed for various periods in wounds, and on theoretical grounds, it seems unlikely that Professor Hamilton's new and ingenious mechanical theory for the formation of granulation vessels will be altogether accepted. In the specimens shown the vessels branch freely and innoculate among the fibres of the sponge; they give off shoots of different sizes, and there is abundant evidence of a new formation of capillaries going on, much in the manner described by Arnold. Even if the capillary blood pressure were sufficient to produce the mechanical effect of forcing out and elongating the capillary loops, it is difficult to understand how that pressure could cause the cell multiplication which goes on in the wall of the elongating capillary. The cells of the wall, indeed, are not simply stretched—they increase in number by division, and the wall of the capillary grows. Several other arguments were brought forward, and in conclusion it was remarked that, as Prof. Hamilton shows, a thrombus in a ligatured artery becomes vascular by the throwing in of granulation loops from the vasa vasorum near the point of ligature—in his own words, "it is nothing more than a granulating surface within a vessel." If this be the case, the pushing in of the loops must be against an intra-arterial pressure, certainly greater than that of the blood in the vasa.

Dr. E. H. BENNETT read a paper on

CONGENITAL DEFECT OF THE RECTUM, BASED ON THE DETAILS OF A CASE WHICH HE HAD TREATED DURING THE WINTER BY LAPAROTOMY, FAILING TO REACH THE BOWEL BY THE PERINEUM.

The variety of deformity exhibited was that in which the anus and other pelvic organs, except the rectum, were normal, and there existed a cord of variable length connecting the anal *cul de sac* with the extremity of the intestine. With the specimen recently acquired, Dr. Bennett showed three examples of the same deformity, contained in the Museum of the Royal College of Surgeons, and contrasted these with an example of complete defect of the anus and urino-genital outlet contained in the Museum of the School of Physic, Trinity College. Having directed attention to the views of Giraldes and of Curling, who have attributed this deformity to obliteration of the rectum by a pathological process, Dr. Bennett showed, from the evidence presented by the specimens, that this view was erroneous, and that the lesion is due to the arrest of development of the bowel, the hypoplastic pouch failing to reach the anal inflexion on the surface of the embryo. He indicated the probable analogy between the muscular cord connecting these parts and such bodies as the gubernaculum testes. He further demonstrated that attention to the position and relations of the cord might enable the surgeon when operating for relief of the deformity to avail himself of it as a guide to the intestine.

Dr. M'SWINEY, Mr. STOKES, and Prof. MACALISTER discussed the foregoing communication.

OCCCLUSION OF THE INFERIOR VENA CAVA.

Dr. F. W. WARREN read a paper on the subject of occlusion of the inferior vena cava, illustrating his remarks with a rare case in which the inferior vena cava was completely occluded by a calcareous tumour, about the size of a bean, growing by a narrow pedicle from the great Eustachian valve. The tumour completely obstructed the vein at the caval opening of the diaphragm, and was adherent to the living membranes of the vein. The specimen was taken from the body of a male, æt. 22. During life, both lower limbs—the front of the abdomen and the anterior aspect of the thorax—were covered with a close network of varicose veins, the head, neck, and upper extremities being perfectly normal in appearance. The patient stated he had these enlarged veins as long as he could remember. He was otherwise perfectly healthy, there being no œdema, no hæmorrhoids, no albuminuria, but he died unexpectedly of enteric fever from perforative peritonitis, and he suffered from œdema of the liver from the onset of the fever. A careful post-mortem examination having been made, the principal channels of collateral circulation were as follows:—The vena was about the size of the latter vein in health; the superficial compensatory circulation was principally carried on by the superficial deep epigastric veins, with the circumflex iliac veins from below anastomosing with the internal mammary and long thoracic veins from above, the source of blood current being reversed and passing from below upwards. Within the vena, just as it opened into the right auricle, the tumour already described was discerned. The vena cava hepatica were not obstructed, as a surgical probe could be passed through them into the right auricle. Dr. Warren was of opinion that the tumour commenced as a fibrinous vegetation upon the great Eustachian valve, and then underwent calcareous degeneration, causing very gradual and finally complete obstruction of the vena. Upon striking the tumour with a pencil or spatula, its stony and calcareous character was readily demonstrated. The tumour did not in any way partake of the character of a thrombus, as it was round, small, isolated, and attached by a narrow pedicle to the valve. Dr. Warren was also of opinion that the tumour was intra-venous altogether in its origin and development.

Dr. MACALISTER, commenting on the paper, stated that the total number of cases recorded of obliteration or absence of the inferior vena cava was probably about twenty-three.

Drs. H. KENNEDY and BENNETT also commented on the paper.

Dr. WARREN replied, and
The Section then adjourned.

SUB-SECTION OF ANATOMY AND PHYSIOLOGY.

At the opening meeting of the Sub-Section of Anatomy and Physiology held in the Albert Hall, Royal College of

Surgeons, the President of the Section, Mr. Alexander Macalister, M.D., F.R.S., occupied the chair. Mr. John Freeman Knott, F.R.C.S.I., Sub-Sectional Secretary, was in attendance.

EXHIBITION OF SPECIMENS.

Dr. D. J. CUNNINGHAM exhibited frozen sections through various parts of the human body.

Dr. P. S. ABRAHAM exhibited (1) a specimen illustrative of the occurrence of two superior venæ cavae in the human subject; and (2) sections of certain tissues in lower animals.

Mr. J. F. KNOTT exhibited (1) section of human hair follicles, demonstrating the connection of Heule's and Huxley's sheaths; (2) frog's nerve, showing Cauntermann's notches; and (3) termination of nerve in frog's muscle, showing Bremer's "sud-dolde."

THE PRESIDENT'S ADDRESS.

Dr. MACALISTER delivered an address on the history of anatomical research in Ireland. Beginning with the ancient Irish medical literature of the tenth and fourteenth centuries, whose anatomical knowledge is borrowed from classical sources, he sketched the progress of teaching and of investigation, touching on the researches of Mullen, Molyneux, O'Halloran in the seventeenth and eighteenth centuries, and those of Macartney, Colles, and their successors in the present century.

THE REFRACTORY PERIOD OF THE AURICLE OF THE HEART.

Dr. PURSER gave the results of some new experiments which he had made on local electrical stimulation of the different portions of the frog's heart. It was found that for the sinus, the auricle, and the ventricle, the law held good that each of these parts is insensible or refractory to single induction shocks during its systole; while, if stimulated during its diastole, it responded by an extra contraction—followed, in the case of the sinus, by a contraction of the auricle and ventricle, in that of the auricle by the contraction of the ventricle. Some observations were made on the circumstances which influenced the rapidity with which the contraction of the ventricle follows that of the auricle.

Dr. THORNLEY STOKER called attention to the extreme practical importance of Dr. Purser's results in explaining how the murmur of mitral stenosis may be sometimes pre-systolic, and sometimes post-diastolic.

The Sub-Section adjourned.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

IRIDECTOMY IN CATARACT EXTRACTION.—M. Terrier read, at a recent meeting of the Paris Academy, a paper "On the Necessity of Abandoning Excision of the Iris in the Extraction of Cataract, and of returning to the old French Method." Referring to the former French method (Daviel's), which was to make a large corneal flap for the extraction of the opaque crystalline lens, he said that it is necessary if we abandon iridectomy in this operation, to do so. In Jacobson's flap method, and especially that called *combined linear*, where, as directed by Von Gräfe, iridectomy was practised, this way of operating remained a veritable necessity. Without this excision, the crystalline lens was only extracted with difficulty by contusion of the iris and mechanical force, causing exposure to hernia and anterior synechia. Relying on the extraordinary results produced by iridectomy in acute glaucoma, we admit that, according to Von Gräfe, this mode of operating prevents inflammation following. Iridectomy has not, then, simply a mechanical advantage, but also an antiphlogistic one, and it has been generally performed notwithstanding sundry protestations from Von Hasner and others. But things became somewhat modified by the transformation of the linear method. For ~~linear~~ or almost peripheral linear incisions made in the

sclerotic-corneal flap, those which were entirely peripheral, especially in the cornea, were substituted. This was the beginning of the flap method; soon these portions were made larger (by Liebreich, Warlomont and Lebrun, and Maurice Perrin, of Wecker), and then for the first time did the operators discuss the value of iridectomy. Some, following the precepts of Von Gräfe, greatly reduced the practice of it (Sichel, &c.); others regarded it only as a power-giving method (Maurice Perrin); and the remainder of them considered it useless and abandoned it (Liebreich, Lebrun, and Warlomont, of Wecker). In fact, by returning little by little to the flap method, iridectomy, which is now advocated for cataract operations, will be abandoned. This M. Galezowski has done by substituting the cutting of a flap for the linear section, which before this he has so much extolled. This change will explain the cause of some unsuccessful operations and accidents of ocular phlegmon in spite of the methodical use of antiseptics and the phenic spray. The new method proposed by M. Galezowski will, according to the reporter, only be another aspect of the flap method. When operating, M. Galezowski makes the puncture and counter-puncture at the sclerotic-corneal limit, then cuts a flap the top portion of which covers two millimètres of the edge of the sclerotic. The crystalline lens, says the author, is then easily extracted, as the pupil becomes dilated under its pressure and leaves the passage free; the iris returns to its place immediately, or can be easily put back by a pointed silver instrument. According to the author, the semi-elliptic flap method would have this advantage over Davill's, that it allows an easier coaptation and a more rapid cicatrisation. This operation has been performed, it is said, fourteen or fifteen years ago by M. Luoi, with this difference, that then the flap was about one millimètre larger at the base. However that may be, out of forty cases performed by M. Galezowski, there were five difficult cicatrisations of the flap in spite of the semi-elliptical incision, and the absence of iridectomy gave place to four hernia cases of the iris, two of which were accompanied by anterior synechia, and for two others excision of the iris became absolutely necessary. There were also three cases of iritis, one with hypopyon. Ought these results to make the profession abandon the combined linear method more or less modified by English ophthalmologists? Should we give up the practice of making a small flap which has been known to surgeons for some time, to return to the old method of Davill or Beer? M. Terrier does not think we ought to, having regard to the few facts related by the author, and to the absolute insufficiency of details in the operation and the results obtained.

ANEURISM OF THE BASILARY ARTERY.—M. Runeberg was called in consultation over a peculiar case a few days since. A strong-looking man, æt. 56, having suffered for a whole day from headache, was found unconscious in bed the next morning. It was at first diagnosed as a case of poisoning by chloroform. The pupils were large, dilated, and fixed, and showed no reaction with light. The head was forced forward, the tongue very far back, and hindering respiration, which at other times was full and regular. The pulse was slow, but the force good and equal, and the beating of the heart was normal, muscular reflex following the pricking with a pin. Chloroform poisoning was, nevertheless, not the cause. Runeberg thought of hæmorrhage of the brain membranes. The general state did not, however, improve; the reflexes became better developed, the respiration more superficial and frequent; as the heart weakened, the teguments became cyanised and covered with perspiration. The

temperature rose to 40°, and the patient died in this condition two days afterwards. The post-mortem examination showed that there was an aneurism of the basilar artery opening into the membrane of the brain. The blood poured into the sub-arachnoid spaces at the inferior surface of the hemispheres. There was not any other cause of death. The rupture of the aneurism was probably signalled by the headache; the sub-arachnoid flowing of blood took place probably during the sleep which preceded the comatose accidents.

THE MEDICAL BILL.

Analysis of the Bill (all important phrases verbatim) introduced in the House of Lords by Lord Carlisle on behalf of the Government on Thursday, 8th of March.

BE it enacted, &c.

PART I.

ADMISSION TO MEDICAL PRACTICE.

2. The Medical Register shall be continued.
3. A person, whether male or female, who has proved his or her competency in medicine, surgery, and midwifery by passing the final examination in this Act mentioned, and no other person shall be entitled to have his or her name entered on the Medical Register.
4. A registered practitioner may "practise the callings of medicine, surgery, and midwifery, or any of the said callings, in the United Kingdom, and (subject to any local law) in any other part of Her Majesty's dominions, and may recover any expenses, charges in respect of medicaments or other appliances or any fees to which he may be entitled," Members of Colleges of Physicians exempt.
5. A registered practitioner shall be exempt from serving on all juries and corporate offices.
6. A person shall not be entitled to recover in any court of law any expenses, charges, or fees for any medical or surgical advice or attendance, or for any operation, unless he proves that he is a registered practitioner.
7. Any expression importing a medical practitioner, when used in any Act, shall be construed to mean a registered medical practitioner within the meaning of this Act.
8. Nobody but a registered practitioner shall hold any appointment.
 - (a) In the military or naval services, or
 - (b) In any hospital, &c., not supported wholly by voluntary contributions, or in any lunatic asylum, &c., union workhouse, or other public establishment, or
 - (c) To any friendly or other society, or
 - (d) As a medical officer of health, or
 - (e) In any emigrant or other vessel.

Medical Boards.

9. (1.) There shall be established in each part of the United Kingdom a medical board.
- (2.) The numbers of the medical boards shall be—
- (3.) Fifteen chosen for England. Two each by Oxford, Cambridge, and London Universities; one each by Durham and Victoria Universities; three each by the London Colleges of Physicians and Surgeons; and one by the London Apothecaries' Society.
- (4.) Eleven for Scotland. Three by Edinburgh University; two each by Glasgow and Aberdeen Universities; one each by St. Andrew's University, Edinburgh Colleges of Physicians and Surgeons, and Glasgow Faculty.
- (5.) Ten for Ireland. Two each by Dublin and Royal Universities; three each by Colleges of Physicians and Surgeons; and one by Apothecaries' Hall.
- (7.) A medical board shall be renewed every five years by the whole of its members retiring, being eligible for re-election.

- (9.) Any person of full age shall be qualified to be elected a member of a medical board.
- (12.) The same person may be a member of more than one board.
- (13.) The Privy Council on the report of the Medical Council may increase the number of authorities entitled to return a member.
- (14.) Or may deprive any authority of the privilege of returning a member.
- (15.) And shall every ten years take into consideration the number of members returned by the constituent authorities, and add to, or reduce the number of members.

10. The medical board shall make, revoke, alter, or add to a scheme for—

- (1.) The holding of final examinations for the admission of candidates to registration, and
- (2.) The appointment of examiners; and
- (3.) The nature and conduct of such examinations, and the qualification of candidates as to age, moral character, and any other matter necessary or expedient to be determined by rules. Provided that—
 - (b.) Provision shall be made for the admission of women to the examinations, but such distinctions (if any) may be made as may be judged proper between the cases of men and women, so however that the examinations of men and women shall be in all general respects equal as respects proficiency in medical knowledge and experience.

So far as is practicable a uniformity of standard shall be aimed at in the final examinations held by the medical boards of the several parts of the United Kingdom.

Any scheme, or alteration of a scheme, shall be of no validity until it has been approved by the Medical Council and confirmed by the Privy Council.

11. A medical board may delegate any of their powers to a sub-committee.

Medical Council.

14. The Medical Council shall consist of eighteen persons, to be chosen as follows:—
- Six Crown nominees;
 - Two direct representatives for England;
 - One for Scotland;
 - One for Ireland;
 - Four elected by the medical board of England;
 - Two by the medical board of Scotland; and
 - Two by the medical board of Ireland.

Any person of full age shall be qualified to be a member of the Medical Council whether he is or is not a member of the medical profession, and may be a member of medical board and also of the Medical Council.

The Medical Council shall be renewed every five years by the whole of its members retiring and their places being filled up as above set forth.

A casual vacancy occurring amongst the direct representatives shall be filled up by election by the registered medical practitioners of that part of the United Kingdom from whence the member who created the vacancy was returned. If it occurs during the fourth or fifth year after any quinquennial renewal of the Medical Council, shall not be filled up unless the Medical Council so direct.

15. The Medical Council shall, in addition to any other duties, visit examinations conducted or recognised for the purposes of this Act, and inquire into the sufficiency thereof.

The Medical Council shall have power by order to regulate the performance of their duties by each medical board. Any medical board aggrieved by any order made by the Council may appeal to the Privy Council.

16. The Medical Council may delegate functions to a sub-committee.

PART II.

Medical Education.

19. Every candidate for final examination shall comply with the following requirements; that is to say—

- (1.) He must have passed such a preliminary examination, and
 - (2.) been admitted as a medical student, and
 - (3.) he must have passed through a prescribed course of medical education, and such medical education shall comprise such experience in the practice of medicine, surgery, midwifery, and the acquisition of such professional and scientific knowledge as may be necessary for the purpose of securing efficiency in his exercise of the profession of medicine, surgery, and midwifery.
20. Each medical board shall make (and revoke, alter, or add to) a scheme with respect to the following:—
- (1.) The preliminary examinations, and
 - (2.) The course of medical education.
- In defining the course, the scheme shall describe—
- (a) The schools which are to be considered proper places of education;
 - (b) The times and places at which examinations are to be held; and
 - (c) The authorities which are to be considered competent for conducting or for appointing examiners to conduct such examinations, and such examining authorities may be the medical board themselves, or any medical authority.

Any scheme shall be of no validity until it has been approved by the Medical Council.

21. It shall be the duty of each medical board to ascertain by inspection or otherwise the sufficiency of the education provided by schools, and by visitation or otherwise to inquire as to the examinations held by any recognised examining authority, and to take such steps as may be necessary for depriving any school or any authority of recognition.

PART IV.

Quacks' Clauses.

23. (1.) If any person, whether registered or not, takes or uses a medical title which he is not entitled to take or use, he shall be liable to a penalty of twenty pounds.

(2.) If any person, whether registered or not, takes or uses a medical title which is by this Act not permitted to be entered on the Register, he shall be liable to a penalty of twenty pounds:

Provided that a person shall not be liable—

First, if he holds a diploma which authorises him to use the medical title granted by a medical authority recognised by this Act; or

Secondly, if he is not ordinarily resident in the United Kingdom, and holds a diploma which authorises him to use the title complained of, and to practise in the country in which the diploma was granted.

(3.) If any person not registered represents himself to be a registered medical practitioner, or uses any name, title, addition, or description implying that he is a registered medical practitioner,

he shall be liable to a penalty of twenty pounds: Unless he shows that he has been and is entitled to be registered, but that his name has been erased therefrom in error.

(4.) If any person who is not registered, and who practises for gain, or professes to practise, or publishes his name as practising medicine or surgery, or who receives any payment for practising medicine or surgery,

(a) represents himself to be a physician, surgeon, doctor, or apothecary; or

(b) uses any designation denoting that he is qualified by law to practise,

he shall be liable to a penalty of twenty pounds.

(5.) Prosecutions for offences against this section may be undertaken only

(1.) By any person authorised by the Medical Council; and

(2.) By the Public Prosecutor for the Division of the Kingdom, or by a person authorised by the medical

board for same, or by a recognised medical authority, medical board.

This section shall not prevent

- (1.) A person from using the designation of midwife, or
- (2.) A person holding a licence in midwifery from using the designation of licentiate in midwifery, or
- (3.) A registered dentist from using any title which he is entitled to take or use under the Act.

Medical Authorities.

35. Any authority authorised to grant diplomas may, notwithstanding any charter or Act, grant medical diplomas to persons of both sexes, provided that—

A woman who receives a diploma from a medical authority which does not already grant a diploma to any woman, shall not, be thereby entitled to any share in the management of that authority.

36. Any authority may, if it thinks it expedient so to do, admit without further examination any person who has passed a final examination in pursuance of this Act to its lowest qualification.

37. Nothing in any Act or charter shall prevent any medical authority from making any such changes in its constitution or practice as may be necessary to enable such authority or school to conform to this Act.

PART V.

Expenses and Medical Funds.

38. The three medical boards and the Medical Council, shall respectively form funds.

Each medical board fund shall be applicable to the payment of—

- (1.) The expenses of its examinations.
- (2.) The reasonable expenses and remuneration to members of the medical board in attendance on such board.
- (3.) Expenses in respect of officers and rooms, and any expenses in respect of elections, visitations, or otherwise which the board may properly incur.

Any surplus shall be paid to the Medical Council fund. The Medical Council fund shall be applied in payment of—

- (1.) The reasonable expenses and remuneration to members of the Medical Council in attending on such council.
- (2.) Any expenses in respect of officers and rooms, &c., which the Medical Council may properly incur.
- (3.) The expenses of the election of direct representatives.
- (4.) The expenses of maintaining any such medical museums and medical libraries belonging to any medical authority for the time being authorised to return a member to a medical board, as may before the passing of this Act have been ordinarily maintained for general public purposes by such authority in their capacity of grantors of qualifications for registration under the Medical Act, 1858, and have been so maintained out of fees paid by applicants for such qualifications, and may be of such importance to the promotion of knowledge in medicine or surgery as to deserve to be maintained out of the funds of the Medical Council.

The amount of the remuneration for members of a medical board shall be determined by that board with the assent of the Medical Council.

An account shall be rendered by the Medical Council to the Privy Council, and any surplus shall be applied for the benefit of the medical profession, or in such manner as the Medical Council may determine.

For the purpose of supplying moneys to form each medical fund, each medical board may charge such fees for its examinations and for the registration of medical students within its part of the United Kingdom as that board with the assent of the Medical Council and sanction of the Privy Council may determine.

The Medical Council may, with the sanction of the Privy Council, charge

- (a.) For copies of the pharmacopoeia and of the medical register, and

- (b.) A fee for the registration of practitioners, and
 (c.) An annual fee for keeping the name of each medical practitioner on the register, and
 (d.) Fees of small amount for making entries on the register by way of alteration of names or addresses, &c.

PART VII.

Transition from Old to New Law.

54. The first election of a medical board in each part of the United Kingdom shall take place in January, 1884.

Subsequent elections in the January of every succeeding fifth year.

The returning officer shall be such person as the Privy Council may appoint in each part of the United Kingdom.

The returning officer shall issue a precept to each constituent body, requiring such body within ten days to hold an election of members of the medical board.

Each of the medical authorities in each part shall return such member or members in manner in which such authority is accustomed to return a member or members representing its body.

The first medical board in each part of the United Kingdom shall come into office on Feb. 1, 1884.

The first meeting of the medical board shall take place within the first fortnight in February.

55. The returning officer for the Medical Council shall be the registrar of the Medical Council.

For election of members by the medical boards, the returning officer of the Medical Council shall, within the first seven days of March, issue his precept to each of the medical boards, requiring them within ten days to certify to him the names of the members elected by each such medical board.

The election of such members shall be conducted as may be provided by regulations to be made by such board.

For the purpose of the election of members to be elected by the registered medical practitioners resident in England, Scotland, and Ireland respectively, the following steps shall be taken:—

For election of direct representatives, the returning officer of the Medical Council shall, within the first seven days of March, issue his precept to each of the medical boards, requiring such board to cause the proper number of members to be elected within fourteen days.

The election shall be conducted as follows:—

- (1.) The nomination paper of each candidate shall be signed by not fewer than twelve registered medical practitioners; and
- (2.) The returning officer shall forward by post to each registered medical practitioner, resident in any part of the United Kingdom, at his registered address a voting paper.

The first Medical Council shall come into office on March 31, 1884.

The first meeting of the Medical Council shall take place during the first fortnight in April.

56. Each medical board shall, before May 1, 1884, submit to the Medical Council a scheme—(1) for the final examination of medical students within its division, and (2) for the medical education of students within its division.

The scheme or schemes so submitted shall be settled by the Medical Council and forwarded to the Privy Council for confirmation before September 1, 1884.

Any objections to such scheme or schemes shall be considered by the Privy Council before November 1, 1884, on which day at latest the scheme for the first final examination and for the admission of students thereto shall be deemed to come into force.

The first final examination shall be held on such day, not later than the 1st of March, 1885, as the Privy Council may direct.

57. Persons may continue to be registered as medical practitioners in manner heretofore in use up to January 1, 1885.

58. When the medical board of any part of the United Kingdom comes into office the branch council in that part of the Kingdom shall cease to exist, and all property

belonging to such branch council shall be transferred to the medical board.

61. The existing officers of the branch council in each part of the Kingdom, and of the General Medical Council, shall become the officers and servants of the medical board and of the new council respectively at the same salaries and with the same tenure of office as they possessed under the branch council.

[The parts relating to foreign practitioners, medical titles, management of Register, medical boards, &c., approval and confirmation of schemes, saving clauses, dentists, and schedule, will be inserted in our next issue.—ED. M. P. & C.]

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hautefeuille, Paris—post free in advance, £1 3s. 6d. per annum.

SUBSCRIPTIONS FOR RUSSIA are received by Messrs. RAJCHMAN and FRENDELER, 18 Senatoren Street, Warsaw—post free £1 5s. 0d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York by Messrs. WILLMER and ROGERS; Philadelphia, by Dr. BRINTON: post free in advance, 5½ dollars (£1 3s. 6d.) per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-Office Order.

The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, MARCH 21, 1883.

THE MEDICAL BILL.

We print to-day, at as great length as possible, an analysis of the Medical Bill introduced by Lord Carlingford on Thursday, the 8th inst., and standing for a second reading on the first Thursday after the Easter recess. Our readers will best understand its principles from the following outline:—

1. A divisional board for each division of the kingdom is to be formed by delegates from the licensing bodies therein.

2. That board will have four functions—*a.* To concert a complete education scheme; *b.* To hold final examinations for admission to the Register; *c.* To supervise primary examinations, which will continue to be held by

the licensing bodies; *d.* To send forward delegates to the General Medical Council.

3. Licensing bodies will continue to grant diplomas on any terms they please (subject to the supervision of the board), but these diplomas will not be registrable; they will, however, be necessary for any one going for the *final* examination of the board.

4. The Medical Council will be rebuilt, and reduced in number to eighteen—viz., six Crown nominees, four delegates elected by the profession at large, and eight elected by the divisional boards. Licensing bodies will cease to send representatives.

5. Foreign and colonial diplomas will be registrable under certain restrictions.

6. The law against the fraudulent use of medical titles will be strengthened and its ambiguity removed, but practice by unregistered persons will not be forbidden.

After careful consideration of the provisions of the Bill, we would pronounce it good in principle and well-intentioned in its mechanism, but open to great improvement of detail, and of doubtful value if the more important of these improvements cannot be effected.

As we have said, it deals exclusively with *final* examinations, which we assume to mean examinations on the practical application of the fundamental sciences, such as anatomy, chemistry, and physiology, all of which subjects it remits to the primary examinations to be held, as heretofore, by the licensing bodies. This scheme seems to us excellent in principle, for it leaves the educational function in the hands of the licensing bodies, encourages them to compete for success at the final examinations, and gives them a work to do and a reason for existence which would not be so evident if the entire examining function were undertaken by the divisional board. But it is open to the very strong objection that, unless the course of study, examining fee, and standard of examination at these primary examinations be carefully defined, the downward competition of the licensing bodies for the student's patronage and money will be rather intensified than mitigated, inasmuch as these examinations will have no value as qualifications, but will be simply a step towards the final test. If any of the primary examining bodies will give its *imprimatur* to the student for one year's hospital and £5, it will attract the majority of the students from the body which requires two years' hospital and a £10 fee. Ample power is given to the divisional board by the Bill to fix the educational and monetary value of the primary examinations, but no duty is imposed upon them in this matter, nor any method fixed, and it would seem as if the framers of the Bill depended upon the check imposed by the subsequent examination to guard the system against the abuses of competition.

The provisions contained in the Bill against competition between the divisional boards are utterly unsatisfactory. The only proviso on the subject which we can find is as follows:—

"So far as is practicable a uniformity of standard shall be aimed at in the final examinations held by the medical boards of the several parts of the United Kingdom;" and so part of the Bill can we find any clause to prevent the Scotch Board from touting by the lowness of its

curriculum and fees and the ease of its examinations for the Irish and English students, just as the Scotch colleges have heretofore sought to attract patronage by similar means. This is a fault in the Bill which would make it altogether objectionable if it were not remedied, and we think the best adjustment of the matter would be to add to the Bill the clause which was contained in the Government Bills of 1871 and 1880, to the effect that the Medical Council shall revise the schemes of the three divisional boards so as to make them uniform in all respects. The allocation of the funds which will accrue from the board's examination fees must also be the subject of change. By the Bill it is provided that each board, having paid the expense of its own maintenance and its examinations and visitations, shall hand over the surplus to the General Medical Council, who shall allocate the fund so created to "the expenses of maintaining any such medical museums and medical libraries belonging to any of the licensing bodies" as the Council thinks fit. This clause, being interpreted, means that the Irish and Scotch surplus shall not be divided by the Irish or Scotch boards, nor given to Irish or Scotch purposes, but shall be handed over to the Medical Council in London, who might or might not vote a portion of it to the maintenance of the educational bodies from whom the money was indirectly derived. Obviously the Irish and Scotch bodies could not be expected to leave themselves thus dependent on the charity of the London Council, and we think that the Bill should be amended so as to leave to each divisional board the disposal of its own surplus, the proportionate grant therefrom to educational bodies to be previously fixed by the Act itself.

The only other point upon which we take exception to this part of the Bill is the recognition which it accords to the Apothecaries' Companies of London and Dublin, and the Glasgow Faculty, by permitting them to send representatives to the medical boards. We have long been of opinion that these bodies, if they ever had a claim to recognition as licensing bodies, have ceased to possess any such right, and we protest against their being permitted to encumber the medical licensing of the future with their unnecessary co-operation. We submit that the seat which it is proposed that they should occupy at the divisional board shall be given to the direct representative for the division, who will otherwise have no voice whatever in the educational arrangements of his own country.

The clauses of the Bill which deal with the reconstitution of the Medical Council are in all essential respects worthy of approval and hearty support, and are, indeed, so satisfactory as to go far to reconcile us to the faults of the educational sections of the measure. The clauses for suppression of quackery are also satisfactory, so far as they go; and, on the whole, we need not hesitate to say that we welcome the Bill with all cordiality, and trust the Government will not be prevented from doing justice by its means, no matter what the interested opponents of reform may think or say.

CONJOINT MUDDLING.

ASTOUNDING as many of the vagaries recently indulged in by the Royal Colleges of Physicians and Surgeons in London have been, each and all grow insignificant before

the latest and most transcendent folly, which, under the title of a combined scheme of examination, these august institutions now solicit the profession to admire and accept. It will be in the knowledge of our readers—for brief references to the fact have from time to time been made in our columns—that a committee appointed by the two Colleges has for three months past had under consideration proposals for creating a new examination, to be conducted by both corporations together, with the object of conferring the double qualification in medicine and surgery hitherto granted by the colleges severally. The matter having at length been finally settled, the scheme is now before the world; and of all the preposterous attempts that have yet been made to obstruct reform, it may safely be said that none approaches it, even remotely, as a means of preventing advance or improvement if it should, by adverse fortune, fail to meet the fate it so richly deserves.

According to the agreeable and harmonious arrangement entered into by the two Royal Colleges, "each will abstain, so far as allowed by law, from the exercise of its independent privilege of giving a qualification necessary for admission to the Medical Register;" and while so binding themselves to a plan utterly destructive of many of the best traditions of English medicine, they saddle the licence thus to be obtained with a pecuniary liability of *thirty-five guineas*. In other words—and the more plainly this is put just now, the better it will be—two ancient and honourable medical corporations have joined their forces, to the end that their coffers shall be enriched at the expense of the already overtaxed student. From one point of view, however, it is possible to derive satisfaction from the threatened infliction; for nothing could have been more serviceable as proving the utter incompetency of interested corporations to initiate anything in the shape of reform in respect to qualification. The Royal Colleges of England now hold the unenviable position enjoyed by monopolists in combination to exact usurious returns for their wares; and it may be safely assumed that their action in this respect will remove any remaining doubt as to the expediency of dealing with them in a spirit regardless of their private aims or wishes. With abundant opportunity of proving not only anxiety, but also ability to commence in themselves the reform that is now rendered more than ever certain, the chief centres of English medicine and surgery have seized that opportunity to promulgate a "scheme" as remarkable for its neglect of pressing claims on their liberal interpretation of facts, as it is for the avaricious nature of its pecuniary clauses.

Should this miserable combination most unfortunately ever come to shed its blighting light over our schools and students, but one result can be anticipated. The annual migrations of English students in search of Scotch diplomas will be hugely augmented, and with the necessary result that the special kind of education required to enable a successful candidature to be gone through north of the Tweed will be permanently established in southern colleges and hospitals. Selfish consideration of their own material interests would, however, seem to have blinded the combining corporations to the irreparable injury they must perforce

inflict on education by persisting with their most injudicious proposals; and hence it is but too clear that legislation is imperatively called for to prevent the consummation of the worst blunder possible to be committed under existing circumstances.

Of the details of the combined scheme but little need be said. It provides three examinations—the first including chemistry, physics, materia medica, botany and pharmacy, elementary anatomy and physiology: the last two subjects may be passed separately. The second examination includes anatomy and physiology, and these also may be taken at different times. The subjects of the third examination are medicine, surgery, midwifery and diseases of women; and it may be passed in three instalments. This feature of divisional examination is, perhaps, the most favourable instance of good judgment exhibited in the scheme; and of the examination as a whole, it may be at once admitted that it is a proper and sufficient test of knowledge which should entitle to a qualification in medicine and surgery. But when the question of fees is considered, the prospect is much less satisfactory. These are, for the first examination, ten guineas, with additional three guineas for re-examination in *either* part; for the second, ten guineas, with the same amount in case of rejection; for the third, fifteen guineas, with an addition of five guineas for examination in either of the three sections.

Unless the mode of examination is different to that sometimes pursued at the College of Surgeons, it will thus be possible for an especially unfortunate candidate to be mulcted of *sixty or seventy guineas* as the price of his diploma! a monstrous and wholly unjustifiable tax on the resources of a class already sufficiently burdened with monetary impositions.

Unpleasant as it is to record the fact, we must nevertheless admit that examination of the "scheme" induces the impression that the prime object held in view in its foundation has been, not the advantage of medicine, but the pecuniary advantage of the participating Colleges.

THE DUBLIN STUDENTS AND THE IRISH COLLEGE OF SURGEONS.

"A STORM in a teapot" has agitated the studental atmosphere in Dublin within the past week, and has given rise to a good deal of vapouring by young men who did not understand what they were talking about, grinders who were interested in keeping up agitation against educational reform, and newspapers which live by the popularity policy.

Our readers do not need to be reminded that the Council of the Irish College of Surgeons has been engaged for the past three years in warfare with the sham-certificate, apprentice-farming, credit-fee systems which in years past have disgraced Irish medical education and indirectly reflected their discredit upon the College itself. They have endeavoured to make real the course of education which have hitherto been nominal by establishing a complete new system of consecutive annual examinations; they have thus used every means within their reach to protect the student and his parents against the pernicious apprenticeship system by means of which

much of the educational outlay of the student was diverted from the pocket of the teacher into that of the apprentice-farmer, and many of the students were driven from the pursuit of their profession to other avocations in sheer disgust. The College expected and has met with the violent opposition of those who found the old system profitable, but it has persevered in the praiseworthy determination to amend the Irish medico-educational system, of which—the Medical Council being effete and useless—it is the chief custodian. In pursuance of the honesty policy, the Council decreed in June of last year a series of new regulations having for their object to ensure that lectures and hospital paid for by the student and certified by the teacher shall be really attended, and not merely testified, as heretofore, by false testimonials at the end of the year. These regulations require that the actual number of lectures and hospital visits at which the student was present shall be stated on the face of the certificate by the teacher, and certified by the registrar of the school or hospital, and by the student himself, and, to make these proofs of study specific and unequivocal, it was ordered that the certificates should be tabulated, as is done in London and Edinburgh, in a "schedule" for submission to the Inspection Committee of the College. Being thus brought face to face with the impossibility of evading the courses of medical study without the perpetration of a series of specific falsehoods, the teachers and students who had been co-operating in the sham certificate system were driven to their wits' end to comply with the requirements of the College, and the expedient was adopted by one Dublin school of delivering lectures at night, to enable clerks and shop assistants who were engaged daily from half-past nine a.m. to six p.m. to make a pretence of attending lectures between seven p.m. and eleven p.m. This method of evading medical study has been persisted in during the past winter session in the hope that some other method would turn up of evading the proofs of *bond fide* study required by the collegiate certificate regulations.

Within the past fortnight the dilemma in which these gentlemen are placed reached its culmination, because the time had arrived for lodging the proofs of study prior to the first examination for the College licence, and no alternative remained open but to get up a fresh agitation to intimidate the Council of the College from enforcing its own regulations. Accordingly, the party amongst the teachers who manipulate the agitators amongst the students induced a number of the students to organise a demonstration based upon certain ambiguities in the phraseology of the schedule. That such a demonstration was entirely unnecessary could have been easily ascertained by anyone who thought it worth while to ask a question on the subject from those conversant with the regulations in question, or to look at the resolution of Council which put those regulations in force. Anyone doing so would have learned that the new certificate rules had reference solely to the session for 1882-83 and succeeding years, and were in no way coercive in respect of courses of study commenced before that date. Information on the point was probably not very anxiously sought for it being a better line of policy

for the anti-reform teachers to inflame the minds of the students by statements which could easily be disproved, and thus to terrorise the timid members of the College Council. The effort, however, did not, in this instance, succeed, for the Council, upon consideration of the matter, simply referred these gentlemen to its resolution of June, 1882, and maintained its determination to carry that resolution into effect.

We cannot reasonably be surprised or disappointed at the continuous and uncompromising hostility offered to a reform of the educational system in Dublin by those to whom such reform means a very serious loss; but we certainly regret to observe that certain of the students evince an equal readiness to oppose the efforts which the College is making to ensure that their education shall be *bond fide*, and to protect them against the exaction of fees for lectures which they do not want, derive no benefit from, and heretofore have not been asked to attend.

Abuses die hard; and if the College expected to overthrow a system of fraud out of which tens—we might almost say hundreds—of thousands of pounds have been obtained from the student for no value given, the College must have been indeed sanguine. The students ought not, however, to associate themselves with the defence of such a system, for we honestly believe they will find in the Council of the Irish College of Surgeons friends more anxious to deal fairly with them, more regardful of their circumstances and interests, and more independent of personal influences, than they are likely to meet with in the bad advisers who have stimulated their recent proceedings.

But if the Council of the College should have to face the opposition of the students as well as that of the hostile teachers, we hope and believe they will not hesitate to meet it with dignity. The College cannot with honour lend itself to connivance at the evasion of its own requirements and those of the Medical Council, and we hope it will never condescend to purchase off interested clamour by consenting to do so.

BACILLUS TUBERCULOSIS.—ANOTHER STAGE.

WITH every addition to the list of those who engage in experimental investigation of the facts and difficulties surrounding the genesis and history of the renowned bacillus, we are brought to see, always more and more plainly, the absolute importance of admitting and appreciating the mutability, not of opinions only, but often even of recognised theories. In this connection an abstract report of Mr. Watson Cheyne's recent researches on bacillus tuberculosis, and for which we are indebted to the author, is peculiarly instructive; for while devoting himself mainly to verify or disprove previous observers' results, Mr. Cheyne has been able to correct errors which indirectly have affected the validity of conclusions accepted by not a few scientific workers. The claim put forth by M. Toussaint, to the effect that tuberculosis is caused by the presence of micrococci, not approving itself to Mr. Cheyne, he conducted a series of experiments with a view to demonstrate the truth of his own position. Finding Koch's tubercle

bacillus present in undoubted quantity in animals which M. Toussaint had injected with micrococcal fluid, Mr. Cheyne was led to inquire into the means observed to ensure absolute cleanliness of the instruments employed. M. Toussaint trusts mainly to carbolic acid for this purpose, and thinking this reagent might possibly prove ineffectual as a bacillicide, Mr. Cheyne experimented, with the result that he is now able to state that it does not always arrest the development of the bacillus spores. Added to this, thirteen animals were carefully inoculated with micrococcal fluid, the most ample precautions against any other infection being taken, and in no single instance was tuberculosis produced.

By another series of experiments Mr. Cheyne would seem to have successfully disposed of the theory so energetically maintained by Dr. Formad, of Philadelphia, that tuberculosis may be set up by any irritant under appropriate conditions in certain orders of animals—rodents particularly—supposed to be anatomically predisposed to its development. In quite a number of instances the experiments quoted in proof of this assumption were repeated without success, failure being attributed to the fact that precautions were taken against mediate contagion, the possibility of which had not been duly appreciated by the original observers.

A most important, and, at the same time, interesting, part of the report is that in which Mr. Cheyne describes the conclusions he has arrived at in regard to the site and extent of the bacillous deposits in tuberculosis. Always, except when a sort of universal infiltration implicates all the structures involved, bacilli are found only in the epithelioid cells of the lungs, this situation being that of their first deposition. Advancing degeneration may be associated with the presence of bacilli in the caseous mass; but then, also, they are best found on the margin where epithelioid cells exist, originating from the alveolar epithelium, to which the bacilli can, of course, penetrate without difficulty.

We cannot now do more than draw especial attention to the very admirable researches in the prosecution of which Mr. Cheyne has been lately engaged. It should, however, be remembered with satisfaction that his work has been suggested by, and carried out with the aid of, the Association for the Advancement of Medicine by Research; and being the first undertaking promoted by the Society, it has much reason for congratulating itself on the success of its primary essay in aid of scientific medicine.

M. PASTEUR has written from Vacluse, where he now is, to the Medical Academy at Paris, to say that he has found the cause of the disease in pigs, which in the valley of the Rhone alone killed 20,000 animals lately. The disease is caused by a very minute microbe, resembling that which causes cholera in fowls, but it differs in physiological properties, being quite harmless to these latter animals, although it kills rabbits and pigs, particularly white ones. M. Pasteur succeeded in inoculating pigs with microbes obtained by artificial means, and thus preventing their ever having this disease.

Notes on Current Topics.

Laparotomy for Large Omental Tumour.

ABDOMINAL section was performed last Saturday week at the Children's Hospital (Adelaide Road), Dublin, by Mr. Ormsby, of the Meath Hospital. The patient, an unmarried female, aged 26 years, suffered from a large abdominal tumour of six years' standing. Where it sprang from was a matter of doubt. She had never been tapped. She was of short stature and the abdomen was enormously distended, the girth of her body at the umbilicus being 54 inches. She was fully placed under the influence of ether by Dr. Oulton, and Mr. Ormsby operated under the antiseptic spray by the usual median incision, as for ovariectomy, assisted by Messrs. William Stokes, Smyly, Atthill, and Wharton. When the abdomen was opened an enormous quantity of ascitic fluid escaped, and the multilocular tumour then came into view, containing fluid which would not run through the trocar or tube, but was the most part solid. The tumour was not attached to the ovary or uterus, but appeared to spring solely from the great omentum. The pedicle was ligatured with two stout catgut ligatures, and cut off short: the tumour was then removed in front of the ligatures. The abdominal incision was brought together with catgut and silkworm gut sutures, and then dressed with the antiseptic gauze. The girl has not had a bad symptom since. The tumour weighed, together with the fluid removed, 75lbs.

Death of Professor von Sigmund.

CONTINENTAL papers announce the death of this celebrated writer on syphilis. His career is somewhat remarkable. He graduated at Pesth in 1837, and soon after removed to Vienna, where he qualified as a teacher of surgery. He afterwards turned his attention to syphilis, and became a teacher in this branch of medicine. In 1845 he was appointed extraordinary Professor of Syphilis, and held this position *twenty-four years* before being advanced to the ordinary professorship. This latter position he held in conjunction with the well-known Hebra. So well satisfied was he with the early discoveries of Ricord that it has been said of him, that during the whole of his 40 years' activity, he never acknowledged any new discoveries in the domain of syphilis. He died unexpectedly in Padua.

The Parkes Museum.

THE migration of the Museum to its new premises in Margaret Street has been taken advantage of to submit the whole collection to a careful examination, and we believe that the increased efficiency and completeness thus obtained will more than compensate for the delay to which it has led. Special care and attention have been given to the library, which, it is hoped, within a short time may become a representative collection of works on sanitary science. One important advance in the desired direction was announced at the meeting of the Council on the 12th inst., when a communication was read from Mr. Ernest Hart, who has generously offered to present to the Museum a valuable collection of the Health Reports from nearly all

parts of the country, which he has formed during the last seven years. The offer, which included a promise to bind and arrange the reports, was gratefully accepted. The collection will in itself form a library of reference invaluable in its way, and such as is nowhere else available for the use of students of sanitary science. At the same meeting gifts of books, maps, and plans were received from the United States Government, Dr. J. Tatham, of Salford, Dr. John James, and Dr. G. V. Poore; through the kindness of the hon. Edward Erskine, of her Majesty's Diplomatic Service, a number of pamphlets, drawings, and photographs, sent by Dr. Geisse, of Ems. There is a large and well-lighted reading-room, to which members will have access, and in which periodicals and works of reference will be kept. Mr. Edward Chadwick, C.B., has shown his interest in the work of the Museum by offering to present a medal.

Gifts of books, pamphlets, plans and maps bearing on the subject of water supply, both in its geological and engineering aspects, on epidemiology, on vital statistics, and on health resorts will be gratefully received and acknowledged by the honorary secretary, Dr. Dawson Williams, or by the secretary at the Museum, 74A Margaret Street, Regent Street, W.

Clinical Lectures at Oxford.

SOME time ago, Dr. H. W. Acland, F.R.S., Regius Professor of Medicine in the University of Oxford, resigned the Professorship of Clinical Medicine, of which also he was the holder; and in place of reappointing to the chair thus thrown open, the University decided to create and substitute for it two clinical lectureships, to which, therefore, elections were made on the 13th inst., by the Hebdomadal Council. The Lectureship in Medicine has been given to Dr. E. B. Gray, Exeter College, Senior Physician to the Radcliffe Infirmary; that in Surgery to Mr. A. Winkfield, F.R.C.S., Senior Surgeon to the same institution.

The Transmission of Diphtheria from Children to Fowls.

DR. L. ROTH, of Kissingen, reports a virulent outbreak of epizootic diphtheria in a barnyard of fowls, which he attributes to infection from children. Two children had suffered from scarlatina and diphtheria; and it is supposed that the desquamated epidermic scales, or some of them, had got mixed with the dust of the room and emptied out into the yard along with the other sweepings. Such an observation as this is exceedingly interesting, and seems to bear out some of the statements of Herr M. Wolff made in the course of a recent paper read before the Medical Society of Berlin, "On a Widespread Brute Mycosis." The paper referred mainly to a mycosis that was the cause of death of about 95 per cent. of the grey parrots that were imported from Africa. In it he drew attention to the infectious diseases of domestic animals, which clinically and anatomically run a course exactly similar to those of human beings. He mentioned the fact that anthrax was met with in fowls, geese, and ducks, and exhibited the same phenomena as when its habitat was the mammalia, especially the blue-red vesicles with anthrax bacilli. He also mentioned another devastating

mycosis prevalent amongst domestic birds that bore a complete analogy to diphtheria (*vide* Dr. Roth's observation). Yellow and white-yellow membranes were developed upon the most diverse mucous membranes, having all the characteristics of human diphtheria, so that it could not be removed without causing bleeding. A third disease that had its analogue in man was ulcerative endocarditis, that runs its course with the same valvular changes and multiple emboli in the various organs as in man.

Chloroform Accidents.

WITHIN the past fortnight or so two deaths under chloroform have been reported. The first was that of a labourer aged eighteen years, and occurred in the private practice of Dr. Allison, of Lasswade. The second was that of a child, an in-patient of St. Mary's Hospital, suffering from an affection of the knee-joint. In this latter instance a coroner's jury returned a verdict to the effect that deceased died from the influence of chloroform administered prior to an operation; and we learn that an exhaustive inquiry into all the circumstances surrounding the accident is being undertaken by direction of the governing body of the institution. It might be well if this plan of proceeding were invariably followed whenever death during anaesthesia takes place in public institutions like the great hospitals of this country. In the interests both of the staff officials concerned and of the hospital itself, as well as of the public, it could not but be a much more satisfactory course than the usual one of stopping short at the inquest required by law.

A Simple Remedy for Pregnancy Sickness.

THE oftentimes distressing nausea experienced by pregnant women is probably one of the most frequent affections of a minor kind which tax the ingenuity of the general practitioner to successfully relieve. Of the numerous suggestions and remedies proposed in this connection none is simpler than that recommended by Dr. T. C. Wallace in the *Medical and Surgical Reporter*. This consists of a species of Indian corn familiarly known as pop-corn, which should be quickly roasted in a wire basket, as is done at several American sweetmeat shops in this country; but, of course, without the addition of sugar. It forms a very agreeable, light, and nutritious food, and it is asserted to possess almost the virtue of a specific against vomiting uncontrollable by any of the remedies ordinarily employed.

THE highest annual death-rates per 1,000 last week in the large towns from diseases of the zymotic class were:—From whooping-cough, 1·2 in Birkenhead, and 3·3 in Hull; from scarlet fever, 1·0 in Newcastle-upon-Tyne and in Blackburn, 1·6 in Leeds, and 1·8 in Sheffield; and from "fever," 1·7 in Sunderland, and 2·9 in Blackburn. The 39 deaths from diphtheria included 12 in London, 8 in Glasgow, 6 in Edinburgh, 2 in Salford, 2 in Leeds, and 2 in Sunderland. Small-pox caused 2 deaths in London, 1 in Wolverhampton, 1 in Birmingham, and 1 in Newcastle-upon-Tyne. The mortality was again excessive in Dublin amongst persons of 60 years and upwards and in public institutions.

Decrease of Zymotic Diseases in the Metropolis.

At the meeting of the Metropolitan Asylums Board on Saturday last, reports were presented from the various hospitals for infectious diseases, which showed that at Stockwell 16 had been admitted during the past fortnight, 13 had been discharged, and there remained under treatment 71, while 157 beds were available. At Homerton, 33 had been admitted, 3 had died, and 32 had been discharged, while 173 remained under treatment, and there were 13 beds available. At Fulham, 7 had been admitted, 2 had died, 10 had been discharged, while 56 remained under treatment, and 153 beds were available. At Deptford, 3 had been admitted, 13 had been discharged, and 54 remained under treatment, while there were 126 available beds. At Hampstead, 7 had been admitted, 6 had been discharged, and 29 remained under treatment, while 71 beds were available. The total returns from the small-pox hospitals showed that 25 had been admitted in all, 2 had died, and 20 had been discharged, while 79 remained under treatment, and there were 143 beds available. These figures showed a decrease in every instance, and is satisfactory evidence of the present healthy condition of the metropolis.

University of Durham Medical Society.

THE *soirée* of the University of Durham Medical Society came off in the Wood Memorial Hall and adjoining rooms of the College of Physical Science on the evening of the 14th inst. In success and splendour it surpassed its predecessors. This *conversazione*, commonly spoken of as the students', has come to be looked upon as an annual institution to which many look forward with no little feeling of pleasure. The various rooms, which were elegantly adorned, were scarcely large enough to hold the numbers assembled. Received by the President of the Society, Professor Philipson, and the Committee, the guests proceeded at once into the Wood Memorial Hall, wherein was raised at one end a platform for the various singers, and at the other was gathered together and neatly arranged a choice selection of curiosities, works of art, samples of the industrial productions of the district, photographs, &c. Here at intervals the details of an excellent programme of song and instrumental music were executed, Mr. Mace, a favourite Newcastle tenor, contributing his share in a manner which only added to the good opinion in which he is held in the North. One of the most interesting parts of the concert was the performance of Romberg's *Kindersymphonie*, in which music is collectively or individually elicited from a series of instruments, the chief of which are the piano, violin, violoncello, *schnarre*, *kukuk*, *crachtel*, *nachtigall*, triangle, trumpet, &c., the rendering of which took remarkably well, as much from its poetry as its able execution. We were pleased to notice among the performers the Professor of Chemistry, Dr. Bedson; Dr. Limant, the Senior House-Surgeon; Mr. Dunn, and Mr. Horace Paige. It is only right to add that the success of this part of the entertainment was in a great measure due to the zeal and energy displayed by these two latter. In other rooms were arranged microscopes, scientific instruments, electrical apparatuses, &c. A limelight exhibition of micro-photography had attrac-

tions for many of the visitors. In the exhibit department the Committee were kindly aided by Messrs. Mawson and Swan, Messrs. Brady and Martin, Mr. Winter, and Mr. Robson, besides many other gentlemen who lent curiosities to make this section still more interesting. To Mr. Mears, the esteemed lecturer on anatomy of the College, and to the Committee, is due very great praise for the orderly manner in which they brought the meeting to such a successful issue, as is also the thanks of the visitors for the very pleasant evening which they spent. Messrs. Dunn, M.Sc., Paige, Carter, Plummer, Sternberg, and Race formed the Committee; Mr. Powell acted as Treasurer; and Messrs. Caleb and Lutzenby as Secretaries; Dr. Mears being the Chairman.

Prostitution in Vienna—a Health Book.

DR. MORIZ KRAUS, Secundararzt of the Royal Krankenhaus Wieden, Vienna, recently published an article in the *Wiener Medizinische Zeitung* on the above subject. From it we learn that some time between the years 1860 and 1870 a health-book was introduced as a check upon the spread of venereal diseases. Every registered prostitute possesses one. On the one hand, its possession is an indisputable legitimation, and on the other, a tolerably perfect means of control on the part of the authorities. The book contains (a) the nationality of the person to whom it refers, together with her signature; (b) residence; (c) name and residence of the examining physician; (d) the examiner's decision as to her state of health. Section 1 explains the intention of the health-book, which is to show proof of her having undergone regular and satisfactory medical examinations. Section 7 fixes the remuneration of the examiner at 1s. at the examiner's own house, 2s. at the prostitute's. Section 8 provides that, if the prostitute on examination be found sound, the fact, together with the date of examination, be entered in the book; but if, on the other hand, she be found to be suffering from any affection of the genital organs, or from any contagious disease, the examiner is empowered and required to detain the book. He is then to offer her her choice of the three Royal Krankenhäuser, and in case of her refusal to enter any of these, she is to be detained in a hospital by the police. Finally, she is to be sharply warned that, if she still pursues her calling, a penal prosecution will be the result. Treatment of such cases of venereal disease to the prostitute's residence is unconditionally forbidden. There is finally (e) a tabulated appendix, which contains the condition in which the possessor of the book was found, the date of the examination, and the signature of the medical examiner. By means of this the police commissary has proof at once that the bi-weekly examinations are regularly submitted to in accordance with section 2 of the health-book. Dr. Kraus proposes to render the book more complete, and less liable to abuse, by affixing to it the photograph of the prostitute, to be renewed every three years, her age, and, finally, a small appendix of instructions on the nature and symptoms of the various maladies to which she is, by her calling, of necessity exposed. He cannot help mentioning an interesting circumstance—viz., that of late syphilis has occurred with the lowest possible frequency in the syphilis divisions of the three Krankenhäuser, and he attributes this *scilicet*

liche Thatsache on the one hand to the health-book, and on the other, to rigorous control on the part of the police.

Sanitary Authorities at Loggerheads.

THE frequency with which water companies are prosecuted for an impure or doubtful supply is not a matter for surprise, but it has been reserved for Croydon, one of the pioneers of sewage farming, drains, and other sanitary exigencies, to set an example of a "house divided against itself" in these very matters. On Saturday last a summons was taken out by the Croydon Rural Sanitary Authority against the Croydon Local Board of Health, in which the defendant authorities were charged with causing five cottages situate in Beddington Lane, and built by them since the passing of the Water Act, to be occupied without having obtained a certificate showing there was a supply of water sufficient for consumption and use for domestic purposes. Mr. Blake said the occupiers of the cottages had been drinking water taken from a well, a sample of which, upon being analysed by Dr. Hassall, was found to be contaminated with vegetable matter. Dr. Alfred Carpenter, J.P., said it was a most improper course for two sanitary authorities to be proceeding against one another on that ridiculous matter. After perusing Dr. Hassall's certificate, Dr. Carpenter said if everybody were supplied with water as good as that taken from the well people would be well off. It was impossible in wet seasons to get water of a better quality, or water which was entirely free from vegetable matter. Unfortunately, analyses are very cheaply obtained now-a-days, and the craze for absolute purity, obtainable only on paper, or by stretch of the imagination, only ministers to a perpetuation of the system of vexatious prosecutions.

Research in Sanitary Science.

THE accumulated wealth of some of the City Companies—which the new Municipal Bill of the Government is intended to regulate—has been of late directed into legitimate channels for the furtherance of technical education, the promotion of science, art, &c.; and now we have one of the richest and most munificent of these corporations—one which at a single stroke of the pen gave £20,000 to the London Hospital, viz., the Grocers' Company—issuing a scheme for the encouragement of original research in sanitary science. It consists of two forms of endowment—the one, meant as maintenance for work in progress in fields of research to be chosen by the worker himself; the other, intended as reward for actual discovery in fields of research to be specified from time to time by the Company. With the former, the Company establishes three research Scholarships, each of £250 a year; with the latter, they appoint a Discovery Prize of £1,000, to be given once in every four years. The Research Scholarships are intended as stipends for persons engaged in making exact researches into the causes of important diseases, and into the means by which the respective causes may be prevented or obviated. The Court of the Company propose to appoint to two of the scholarships in May, and to a third in May, 1884. The Discovery Prize is intended to reward original investigations, which shall have resulted in important additions to exact know-

ledge in particular sections of sanitary subject-matter. The Court will, once in four years, propose some subject for investigation, and the first subject will be announced in our columns in May next.

DR. CARTER, of Liverpool, has a very crushing letter in Monday's *Standard* against the promoters of compulsory notification of infectious diseases by medical men. Those who are wavering should read it diligently.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 36, Bombay 33, Madras 39, Paris 26, Geneva 20, Brussels 25, Amsterdam 27, Rotterdam 29, The Hague 25, Copenhagen 28, Stockholm 27, Christiania 18, St. Petersburg 40, Berlin 24, Dresden 23, Breslau 31, Munich 32, Vienna 30, Prague 34, Buda-Pesth 32, Trieste 32, Rome 32, Turin 28, Venice 33, Lisbon 37, Philadelphia 21, Baltimore 26.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Cardiff 15, Portsmouth 17, Derby 18, Edinburgh, Bradford, Leicester 19, Sheffield, Salford, Huddersfield 20, Bristol, Wolverhampton, London 21, Halifax, Plymouth, Brighton 22, Nottingham, Birmingham 23, Birkenhead, Newcastle-on-Tyne 24, Leeds, Norwich 25, Sunderland, Bolton, Hull 26, Oldham, 27, Liverpool, Blackburn 28, Manchester 29, Glasgow 31, Preston 33, Dublin 35.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

STARTLING ACCUSATION AGAINST MR. WILLIAM McEWEN.—The chloroform question at the Glasgow Royal Infirmary has at length drifted into the daily papers. Mr. McEwen has had two letters in the *Glasgow Herald* on the subject, following a very one-sided "leader" which the initiated explain on the first principles of political economy; and Dr. Leishman, an influential manager, followed with a crushing and dignified reply. The staff is represented in the controversy by Dr. James Morton in letters which appear in the *North British Daily Mail* and the *Glasgow News* of the 16th inst. Euphemism is not Dr. Morton's forte, and consequently in this letter his statements are no less trenchant than direct. It seems that in the relations between the staff and the directorate the *merest trifles* were regarded as a *casus belli*; for instance, as Dr. Morton so generously remarks, "such small matters as winking or speaking to a good-looking nurse, or anything that smelt of a scandal, was pounced upon as a perfect tid-bit, although the convener (*horribile dictu*, Mr. McEwen) did not scruple one afternoon to drive off with one of the best nurses from a ward without saying 'by your leave' to the surgeon or his assistant! "We have very genial authority for the statement that success does not so much depend on the lover who woos as on his "way of wooing."

ADDITIONAL MEDICAL INSTRUCTION AT ABERDEEN UNIVERSITY.—Some months ago the Medical Faculty of Aberdeen University expressed its desire of extending the teaching in the Aberdeen Medical School, by encouraging those members of the medical profession who are willing and qualified to do so to give

practical instruction in certain special branches in addition to the instruction given within the University. At a recent meeting of the *Senatus Academicus* a report was presented on this subject in which the Faculty asked the sanction of the *Senatus* to include in the advertisement of the summer medical classes, in addition to the special courses already included in it, three special courses of practical instruction—namely, in *Insanity*, in *Public Health*, and in *Diseases of the Ear and Larynx*. After a very protracted discussion a motion by Professor Struthers, expressing approval of it, was carried by a majority, the counter proposal being directed against the insertion of the course of instruction in *Public Health*. The effect of the decision of the *Senatus* will be that three classes will be added to the list of voluntary classes, by which opportunities of additional practical instruction will be placed within the reach of those who desire it in Aberdeen, as in other schools of medicine, and a deficiency thus far supplied in the final year of medical study.

SALE OF DR. KEILLER'S MUSEUM OF MIDWIFERY.—An opportunity, we learn, offers for acquiring the valuable museum of obstetrical specimens and appliances collected by Dr. Keiller, and used by him for the illustration of his lectures and teaching. That such a collection should be dispersed is a matter of regret, especially as the College of Surgeons is already in possession of an obstetrical museum to which additions might be made with advantage. The College might therefore find a permanent home for Dr. Keiller's collection, and thus add to its strength in a branch of practical medicine for which Edinburgh has for so long been famous, and which in the hands of several rising members of the Extra-Mural School shows no signs of decline.

DUNDEE.—GIFTS TO THE ROYAL INFIRMARY.—At the quarterly Court of the Governors of the Dundee Royal Infirmary, last week, it was stated that the following donations in behalf of the Infirmary, including the proposed children's ward, had been received:—Miss Baxter, £1000; Mr. John Sharp, £1,000; Mr. Armitstead, M.P., £500; and Mr. and Mrs. Gerahom Gourlay, £200—in all £2,700.

INCREASE OF STUDENTS AT THE UNIVERSITY OF EDINBURGH.—We understand that the number of students who have presented themselves for the preliminary examinations in Arts for the Medical Faculty, held last week in the University of Edinburgh, is already over 470, as compared with 406 for the corresponding examinations in March last year.

EPIDEMIC OF MEASLES IN ORKNEY.—The epidemic of measles in the Orkney Islands has spread with rapidity, and there is scarcely a parish in the islands that is not affected. As yet there is no abatement of the disease, but fortunately it continues of a mild type, and few fatal cases have occurred.

ABERDEEN UNIVERSITY HONORARY DEGREES.—The *Senatus Academicus* of Aberdeen University have resolved to confer the honorary degree of LL.D. on the following members of the medical profession—viz., Dr. Robert Farquharson, M.P. for West Aberdeenshire, and Dr. James Ross, of Manchester.

Correspondence.

THE PATHOLOGY AND TREATMENT OF RHEUMATIC ENDOCARDITIS (THE LETTSOMIAN LECTURES).

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—Dr. Sansom gives such an erroneous impression of what I hold and have written on the above subject that I must crave space for a few words in reply to him.

He quotes (*Med. Press*, Feb. 28) from my letter the follow-

ing sentence: "When the endocardium is affected in acute rheumatism there is no general inflammation of its surface such as is found in the pericardium and synovial membranes. The mischief is limited to a small portion of one surface of the affected valves." Here I refer solely to the endocardial lining, and the sentence as it stands is absolutely correct. But when Dr. Sansom separated it from its context, and remarked upon it as embodying my views on the pathology of rheumatic endocarditis he ought to have known that he was giving a very inaccurate account of what I have written on that subject. If he will take the trouble to read again the chapter on endocarditis in my work on rheumatism to which he has referred, he will find that our views as to its pathology are not so much at variance as he supposes, and that much of what he teaches in 1883 had already been insisted on by me in 1881, as the following quotations show. Dr. Sansom says that "one of the chief purposes of his first Lettsomian lecture was to show that the endocarditis of acute rheumatism is much more widely spread than appears by a naked eye inspection," and proceeds thus to describe some of the microscopic changes referred to: "The whole tissue of the valves is swollen; it is seen under the microscope to have lost its normal fibrous appearance and to be infiltrated with cellular elements." Wherein does that sentence differ from the following one, taken from page 137 of my book: "The inflammatory process which takes place in the valvular fibrous tissue gives rise to multiplication of its cellular elements, and consequent thickening of the valve." The two sentences are so like each other, and so exactly describe the same morbid changes, that they might be transposed. The chief difference between them is that mine was written in 1881 and Dr. Sansom's in 1883.

Continuing the subject, he says: "The inflammation, moreover, is not confined to the endocardium; the exudation spreads to and infiltrates the muscular structure to which the valves and tendinous cords are attached, and even the root of the aorta." Here, again, Dr. Sansom is treading in my footsteps. If he will refer to the chapters bearing on the subject in my book he will find much on the subject of rheumatic inflammation of the muscles and fibrous rings, including the root of the aorta. Out of consideration for your space, I satisfy myself with two brief quotations: "The fibrous rings are a common seat of rheumatic inflammation" (p. 162); "The muscular structure is frequently involved in the morbid process" (p. 165); to which I would add one extract from my former letter to you: "The parts which suffer in the heart are the fibrous rings and valves, the endo- and pericardial linings, and occasionally the muscular substance."

I think I have said enough to show that Dr. Sansom and I are not so much at variance as would appear from his letter, and that many of the morbid changes which he describes had already been described by me two years before his lectures were delivered.

But though agreed as to the nature and extent of the changes which take place, we differ materially in our views as to their mode of production.

Dr. Sansom regards the endocardial lining membrane as the primary seat of rheumatic inflammation, and "the bead-like elevations on the surface or borders of the valves as but the concomitants of an extensively diffused inflammation." But if that be so, why do they occur on the valves, and why only on one surface of a valve? Why is it that they are always on the same surface? and why is this surface in the aortic valve always its convex, and in the mitral always its auricular? There must be a reason for this limitation of the bead-like elevations to these particular portions of the endocardial surface. The friction theory supplies an adequate reason, if we only admit a prior thickening of the valve such as both Dr. Sansom and I have described.

When Dr. Sansom says, "I cannot, therefore, accept the friction theory as accounting for rheumatic endocarditis," he conveys the impression that I do accept it as accounting for that disease. In doing so he ought to have known that he was attributing to me views which I do not hold. I have distinctly said that friction is not the cause of rheumatic endocarditis, but a mere incident (though an important one) occurring at a certain stage of that disease: it causes not the endocarditis, but only the roughening of the valvular surface; and it comes into play only after the rheumatic inflammation is established, and the fibrous texture of the valve is already swollen from cellular infiltration. This view of the matter Dr. Sansom seems to have been dimly conscious of, for he adds in an apologetic sort of manner, "though friction may well be

a cause determining the aggregation of cellular elements at certain spots of the endocardium, the formation of beads and the deposit on the devitalised surfaces of the little caps of fibrine with which we are familiar." Why, Sir, that is just what I have said that friction does, exactly the rôle that I have attributed to it; and I am glad to find Dr. Sansom coming round, even though reluctantly, to my view of the matter.

But here I must point out the grave pathological error into which Dr. Sansom has fallen—an error which is at the foundation of all the difference between us. In considering the pathology of rheumatic endocarditis it is essential that we should distinguish between the changes that take place in the endocardial lining membrane and those noted in the fibrous texture of the rings and valves. This Dr. Sansom has failed to do. He accurately enough describes the changes which take place both in the deeper fibrous structure of the valve and in its superficial endocardial covering; but he has failed to recognise that these two structures are essentially different both in nature and function, and that the bead-like elevations which are formed on the surface differ entirely in their mode of production and in their formation from the changes which take place in the deeper structure of the valve. Rheumatic endocarditis consists primarily and essentially in inflammation of the fibrous texture: the endocardial lining becomes involved only secondarily and after the valves have become swollen from cellular infiltration of their fibrous structure. "The swelling it is which makes the valves rub, and the rubbing it is which irritates and roughens the membrane that covers them externally." Both physiologically and pathologically the endocardial lining is to be regarded as pertaining to the vascular canals rather than to the heart. It has no vessels: in the absence of these it cannot be, and as a matter of fact never is, the seat of spreading inflammation. It may be irritated and even have a hole rubbed through it by a valvular vegetation, but the mischief is confined entirely to the one spot, and never causes such general inflammation as would result from a similar agency acting on the vascular pericardium. It cannot itself be the seat of primary inflammation; it is impossible for it to be a source of secondary inflammation in contiguous textures. Rheumatic inflammatory disturbance originating in the fibrous or muscular structures of the heart may extend to and injure the endocardial lining, and generally does so more or less; but the process is never reversed.

But the question has more than a pathological interest. In the vast majority of cases in which the heart is permanently damaged in acute rheumatism the damage essentially consists in injury to the endocardial lining. As I said in my former letter, "the inflammation and thickening of the fibrous structure of the valve may be recovered from: what is not recovered from is the roughening of and lymph deposit on its non-vascular endocardial covering." The former is antecedent to and causative of the latter. If the former can be prevented, or arrested early, the latter will not be developed, and the heart will not be damaged. We know that by the free administration of the salicyl compounds we can arrest and prevent rheumatic inflammation of the fibrous textures of a joint: the fibrous textures of the heart are identical in nature and function with those of the joints; like them, they are subject to rheumatic inflammation: may they not also, like them, have that inflammation arrested and prevented by the free administration of the salicyl compounds? But to get this result in the heart we must see the case early, before the valves are so swollen that they begin to rub from premature contact. That, of course, is the difficulty; but it is as certain as such a thing can be that some such chances do occur; and I am glad to note Dr. Sansom's assurance that he intends to adopt my plan of giving, not salicylate of soda, which cannot safely be given in large dose, but salicin. Let me beg him, and those who may follow his example, to give, as I recommend, thirty grains every hour. But let me beg him, and them also, to bear in mind that the morbid process which the salicin can arrest and prevent is the primary rheumatic inflammation of the deeper-seated fibrous structure of the valve, and not the secondary mechanical irritation and roughening of its endocardial covering.

Yours, &c.,

T. J. MACLAGAN.

9 Cadogan Place, London, S.W.

P.S.—I am pleased to learn from Dr. Quinlan's letter (*Med. Press*, Feb. 23) that salicin has been so generally adopted, and with such good results, in Dublin. Wherever it has been given in the dose which I recommend the same satisfactory results have been obtained.

OUR HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Believing the motto of the *Medical Press and Circular* to be *audi alteram partem*, I crave permission to offer a few comments on your article of last week on "Our Hospitals." In the first place, you are under a misapprehension in saying that, "at length the subject of hospital abuses is beginning to be discussed in the lay press." The subject of hospital abuse has, on the contrary, been pretty freely discussed in the lay press for the last twenty years at least, and apparently without having in any way affected public opinion, either for good or evil. For years the daily morning papers have permitted a good deal of discussion in their columns on the subject, and within the last five years well-written argumentative articles have appeared in *Macmillan*, from the pens of Dr. Fairlie Clarke and Mr. Torrens, M.P. for Finsbury. Many other articles have been contributed to other periodicals; and this is now the second paper which has appeared in the *Nineteenth Century*, the previous one being by Mr. Gilbert, and written in a severe and acrimonious tone, apparently intended to inflict damage on the older-endowed hospitals, and on certain members of the staff, while the lay governors, or managing bodies, in whose hands "the power to effect reforms largely rests," I observed were either let off scot-free or received absolution for their sins. A second Daniel has now come to judgment in the pages of the same periodical; and if he were only as successful in his premises as he is confident in himself and his conclusions, a better case might have been made out, or at least the evils complained of would probably have been clearly understood; at all events, there would have been "a prospect of enlightenment," which you, Sir, devoutly wish to see. As it is, Mr. Burdett's facts and arguments are so confused that they entirely miss the mark, and, to my mind, his "fifteen years' experience of hospitals" has only enabled him to play the part of successful "promoter," whose portrait he draws in lively colours. His own Stock Exchange variety of the limited liability sort will, to all intents and purposes, eventually inflict a grievous injury upon the general practitioner. In Mr. Burdett, then, we have a "promoter" sufficiently behind the scenes to enable him to unmask "the wretched imposter" who, "under the cloak of the sacred name of charity," is diverting funds from their "legitimate channel to found some sham hospital and make it the recruiting ground for building up an enormous practice!" A more preposterous idea never entered the head of a sane man. Such sham institutions must certainly exist, because Mr. Burdett assures us that there are no less than sixteen hospitals of some kind or other that do not appear to receive any donations from the Hospital Sunday Fund, and consequently have not the *imprimatur* of the Hospital Sunday Council to show for their existence. No doubt if inquiry were made a very good reason could be given for the non-appearance of these sixteen institutions in the list of the Hospital Sunday Fund; and then comes the more important question: Do the voluntarily-supported hospitals suffer in any way by the existence of "sham or special hospitals?" Most assuredly they do not, and this fact Mr. Burdett shows in plain figures. He tells us that a considerable surplus remains, amounting to four or five and twenty thousand pounds last year (I have not the exact figures by me) over and above the amount required for the support of the "legitimate hospitals," as you term them. Who, then, is injured by the "hospital promoter," if he exists and has made for himself a "local habitation and a name?"

Anyone acquainted with the rise and progress of our unendowed hospitals will tell Mr. Burdett that in every case they must have had a "promoter." They have all had a very humble beginning, and in most cases a "promoter" has appeared in the shape of a medical man, who at a considerable sacrifice of time and money, and after years of anxiety and toil, has at length succeeded in working up an unpretending dispensary into a stately and well-to-do hospital. The promoter of any other good and useful work would have been said to have acquired some right over it, and hand down his interest to another. But Mr. Burdett is of a different opinion; he objects to vested interests in medical matters, and by the staff of a medical school, because it is part of the hospital that has been built up by the hard work of the medical promoter. He would, therefore, at once put a stop to "the sale of professional and scientific knowledge" to the medical student, because here is another opening for a syndicate, or limited liability company, and forthwith an imposing National School of Medicine will emerge from the ashes of a school out of cha-

racter with the age in which we live; and the new school would, no doubt, go far to abolish hospital abuses. But no; he would not let matters rest here. He demands a commission of inquiry to put hospital management on a new footing. No. A grand idea: he proposes the appointment of a paid commissioner, who shall annually report to Parliament on all questions relating to the relief of the sick, the administrative and executive departments of the hospital, and so forth; and this he feels sure will prove to be a panacea for all the ills hospitals have so long groaned under. We want, however, no centralisation—no middleman between the profession and a paternal Government; no King Stock to swallow up our medical schools; but what we do want is, as Sir James Paget told us at the last meeting of the British Medical Association, to be let alone, to be allowed to manage our own affairs in our own way; and no good will come of any other proposal, I am convinced.

I am, Sir, yours, &c.,

ONE WHO HAS LARGELY CONTRIBUTED
IN TIME AND MONEY TO HOSPITALS.

March 17th, 1888.

King and Queen's College of Physicians in Ireland.—The following candidates, having undergone the necessary examinations for the Licences of this College, received their diplomas during the meetings of the Court in the present month. For the Licence to practise Medicine—

Baker, George Lowbridge, London.
Barry, Thomas David Collis, Liverpool.
Gornley, John William, Drogheda.
Howard, Timothy, Sandymount, Dublin.
Bowe, William John Vivian, Rathgar, Dublin.

For the Licence to practise Midwifery—

Baker, George Lowbridge.
Gornley, John William.
Hamilton, William Robert, M.D., M.Ch. Royal Univ. Ireland, Fivemiletown, co. Tyrone.
Hoey, John Colelough, Kingstown, co. Dublin.
Howard, Timothy.
McGee, William, Donnybrook, co. Dublin.
Bowe, William John Vivian.

The following Licentiates in Medicine, having complied with the by-laws relating to Membership, have received the diploma of Membership of the College:—

Nolan, Andrew O'Kelly, Licentiate 1865, Gort, co. Galway.
Blake, Richard Marlay, Licentiate 1876, Dundalk.

Notices to Correspondents.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 28 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

ERRATUM.—In the announcement of the appointment of Mr. Wm. Berry to the magistracy of Wigan, that gentleman, by a printer's error, is described as House Surgeon to the Royal Albert Edward Infirmary, instead of Hon. Surgeon.

MR. LUNN (Birmingham).—Send up the paper, and we will consider it. **DR. W. HOLSTEIN (Geneva).**—The matter will be considered, and a private note sent on decision.

QUI VIVRE.—We know of a travelling appointment open at this moment; but the medical companion must be a total abstainer, and must be prepared for a long sea voyage to the East. Let us know your views, and we will communicate.

B. O. F.—With pleasure; we have made a note of it.

DR. B. W. C.—Thanks for the information; we have put it aside for a favourable opportunity, which the present does not afford.

MR. S. E. R.—The gentleman referred to died last November; hence the absence of his name from the Register.

IRISH PRISONERS.—The name of Dr. Kinkaid, of Galway, was inadvertently omitted from the list which we gave last week of the delegates appointed by the Irish Prison Surgeons to represent them with the Royal Commission on Irish Prisons.

ANTI-NOXIFICATIONIST.—1. The Act does not apply to London, and fortunately there seems to be no present inclination towards saddling

the profession of the metropolis with detective duties. 2. From the half-yearly report of the medical officer of health for the port of London, there were very few cases of infectious diseases amongst the shipping of the Thames during the half-year just ended; those that occur are reported by the captains, and means are at once adopted for removal to hospital ship at the entrance to the port. 3. We are not cognizant with the mode of procedure at the port of Liverpool; but in the case of the town, the profession there decided, by an overwhelming majority, to have nothing to do with the Act.

DR. SAUNDERS.—Such works do an infinite amount of injury to scientific study; but the present artificial system of examination unfortunately calls for their production. So long as "cramming" is held to be an essential method of preparing for examinations, so long will cram-books continue to issue from the press. We regret the fact as much as you possibly can, but protest has hitherto been in vain.

DR. FIREPATRICK.—Your letter is unavoidably crowded out of the present number.

SANITARIAN.—The annual Congress will, we are informed, be held this year in Glasgow on Sept. 25th and following days. It is too early yet to give detailed arrangements; but the discussion of papers will form the principal business, as heretofore.

DR. G.—THADDA. We hope to publish the lectures when the present pressure on our space is relieved. Slips have been duly received.

PATERFAMILIAS.—You will find all the necessary information on reference to our "Students' Number," Sept. 30th, 1888.

A CONSTANT READER—Sulpholins Lotion.—Your formula is truly good. Use precipitated sulphur instead of sublimed, and half the quantity of camphor. The best sulpholine lotion is that of Bary (see Trousseau's Therapeutics, vol. iii, p. 289). Take one dram of potassium sulphide, two of cacao butter, and up to eight ounces of oil of sweet almonds. This forms a soap which "loses its causticity while retaining the general properties of the sulphur." It can of course be made stronger.

Vacancies.

Charing Cross Hospital.—Assistant Physician and Assistant Physician-Accoucheur. Applications to be addressed to the Medical Committee on or before March 31st.

Chichester Infirmary.—House Surgeon and Secretary. Salary, £100, with board and lodging. Applications to be sent to the Secretary on or before April 7th.

Liverpool Northern Hospital.—Assistant House Surgeon. Salary, £70, with residence, &c. Applications to be addressed to the Chairman of the Committee not later than March 31st.

Manchester Royal Infirmary, Dispensary, and Lunatic Hospital.—Honorary Assistant Physician. Applications to be addressed to the Chairman of the Board not later than March 31st.

Nottingham Dispensary.—Resident Surgeon. Salary, £300, with apartments, &c. Election, April 2nd.

Royal Academy of Arts.—Professorship of Anatomy, tenable for five years. Applications to be addressed to the Secretary on or before March 24th.

Appointments.

BATEMAN, H. E., M.B.C.S., L.R.C.P., House Physician to the Royal Hospital for Diseases of the Chest, City Road.

EVANS, J. F., M.B., House Physician to the Bristol Royal Infirmary.

FOLKES, F. H., M.B.C.S., House Surgeon to the Salford Hospital.

HINKINGS, J. W., L.R.C.P., L.R.C.S.Ed., M.R.C.S., Medical Officer to the Second District of the Bromyard Union.

KING, D. A., M.B.Lond., M.R.C.P., Assistant Physician to the West London Hospital.

MARSH, C. J., L.R.C.P.Ed. M.R.C.S., Medical Officer to the No. 1 District of the Yeovil Union.

MORRISON, J. T. J., B.A.Cantab., M.R.C.S., House Surgeon to Guy's Hospital.

SMITH, W. H., M.R.C.S., Medical Officer and Public Vaccinator to the Boston District and Workhouse of the Boston Union.

STANGER, W., F.R.C.S.E., Medical Officer to the Walton District of the Wakefield Union.

STORRAR, W. M., L.R.C.S., L.R.C.P.Ed., Junior House Surgeon to the Carlisle Dispensary.

SUTTON, S. W., M.B., L.R.C.P.Lond., Resident Clinical Assistant to the Hospital for Consumption, Brompton.

YOUNG, A. H., M.B., M.Ch.Ed., F.R.C.S., Honorary Surgeon to the Salford Royal Hospital.

Births.

HOAR.—March 13th, at Maldstone, the wife of C. E. Hoar, M.D., of a daughter.

MACDOWELL.—March 12th, at Bellinglass, the wife of Dr. F. V. MacDowell, of a daughter.

PALMER.—March 4th, at Crossmaglen, the wife of Benjamin Armstrong Palmer, M.B., of a son.

SAVAGE.—March 16th, the wife of George H. Savage, M.D., M.R.C.P. London, Medical Superintendent of Bethlem Hospital, London, of a son.

Deaths.

HUGHES.—March 5th, at Roscommon Street, Liverpool, Ambrose Cecil Hughes, M.D., F.R.C.S.L., aged 59.

LOWRY.—March 8th, at West Malling, Kent, Thomas Harvey Lowry, M.D. (late R.N.), son of the late James Lowry, M.D., R.N., of Maldstone and Donoughmore, aged 66.

ON

STERILITY IN WOMAN.

Delivered in the Royal College of Physicians, London, February, 1883.

By J. MATTHEWS DUNCAN, M.D., F.R.C.P.L., Physician-Accoucheur and Lecturer on Midwifery at St. Bartholomew's Hospital, &c.

LECTURE II.—PART III.

ITS THEORY OR CAUSATION.

In Galton's statement of the actual infertility of heiresses there is observable a remarkable comparative paucity of male issue—a fact which goes, like many others, to confirm the ancient and still prevalent opinion that relative sterility or weakness of reproductive energy tends to the production of females rather than males. This department of the study of sterility I shall not enter on; the causes of the excess of females over males in all births being the subject of an extensive literature, and its relations being too numerous and complicated for advantageous discussion in this place. But I may state that I have long been impressed with a belief, in accordance with the chief pertinent facts, that the excess of female births is due to the prevalence of a degree of weakness of reproductive energy. Excess of female births is coincident with other evidences of sterility.

We have already given reason for believing that when a woman bears above ten of a family she shows an unnatural or excessive amount of fertility; and this belief is corroborated by the demonstration we now propose to give that excessive families occur chiefly in women who are married in the sterile age, or ages of weak reproductive energy characterised by absolute sterility and by morbid production, whether abortive, premature, or mature. At present we only consider the production of mature children, and we find the unnatural intensity of fertility in the young shown by absolutely large number, that is, above ten; while in the elderly it is shown by rapidity of births or intensity of fertility, so long as it lasts; and we may here remark that

it has been elsewhere proved that for such women as begin childbearing late in life, there is a prolongation of the period of fertility beyond the average age of ceasing to bear, not a prolongation, as estimated from beginning to end, of actual childbearing.

That the fertile younger are more fertile than the fertile older is shown by the following table of data derived from

TABLE XVII.

Showing the Fertility of Mothers Married at Different Ages.

Years elapsed since birth of first child.	Average number of children to each marriage formed at ages—			
	16-20.	21-25.	26-30.	31-35.
10	5.05	4.51	4.42	3.44
20	7.68	7.01	6.43	3.00
30	8.41	7.89	6.80	7.00
40	10.85	8.24	5.00	4.00

St. George's-in-the-East. That the younger fertile have a longer perseverance in fertility than the fertile older is shown by Table XVIII. derived from my work on Fecundity. That the unnatural intensity of fertility in women bearing large families begins with the commencement of childbearing is shown by Table XIX. from Ansell, which demonstrates the rapidity, only up to the birth of the third child, in families of various numbers. Up to the third birth the rapidity is twice as great in families of sixteen or more as in families not above three, and it is easily counted that while the small families came slowly, and the excessive families quickly, the families from seven to twelve came nearly at the average rate of one every eighteen months. That the unnatural rapidity of childbearing in excessive families continues throughout childbearing life is shown clearly by Tables IV. and V. In my table the quickest childbearing is every ten months, the family being nineteen in number. In Ansell's table the quickest is every fifteen months, the family being eighteen.

Lastly we show, by a table framed from the Edinburgh and Glasgow data, that the wives beginning fertility at

TABLE XVIII.

Showing the Amount of Continence in Fertility of Wives Married at Various Ages, as shown within Twelve Months.

Age of mother at marriage..	15-19	20-24	25-29	30-34	35-39	Total.
The number child-bearing in the 5th year of married life is 1 in	2.6	2.7	4.1	4.9	10.5	3.2
The number child-bearing in the 10th year of married life is 1 in	3.2	4.0	5.9	8.7	—	4.4
The number child-bearing in the 15th year of married life is 1 in	4.6	6.8	18.2	37.4	—	8.0

13, 14, or 15	1.06	2.40	3.81
16 or more	0.96	2.15	3.47

advanced periods of life have an unnatural intensity of fertility while it lasts, a greater intensity than that of women married and beginning to childbear at the best ages. (See Table XX.) The table reads thus : To take the second row of figures—Fertile women five years married and under ten have, if they are now from fifteen to nineteen years of age, 2.5 children; if now from twenty to twenty-four years of age, 3.19 children; if now from twenty-five to twenty-nine years of age, 3.75 children, and so on.

TABLE XX.

Showing the Intensity of Fertility in Wives Mothers of Different Ages.

Duration of marriage.	Mother's age.

30 years ..	—	—	—	—	—	—	13.000

Multiparity is a term already well recognised as implying that the subjects of it have had two or more pregnancies and births; but a woman may bring forth two or more children at once, and to this condition we apply the term pluriparity. The most common degree of pluriparity is the production of twins, these occurring about once in every eighty pregnancies. Triplets and higher numbers are very much rarer, and the rarity increases with the number.

Chiari, Braun, and Spaeth have given good evidence that abortions are comparatively more frequent in plural than in ordinary pregnancies. McClinton, founding on large ex-

perience, shows that hydramnios is also common. Acrophalous monsters are found only in plural pregnancies. Monstrosities of all kinds are commoner in plural than in ordinary pregnancies. There are more dead-born children in plural pregnancies. The children born alive in plural pregnancies are more difficult to rear. "The proportion," says Ansell, "of infants that are stillborn or die soon after birth is, in the case of males nearly five times, and in the case of females nearly four times, greater in multiple than in single births."

Subsequently we shall adduce evidence that pluriparity is specially associated with idiocy and imbecility of the children, and that it specially affects the sterile ages, or ages of weakness of reproduction. Excessive family, that is, above ten in number, specially affects the same ages, and is dangerous to the lives and injurious to the health of both mothers and children. Both have therefore an alliance with sterility.

In a case of quintuplets the mother's age was forty and the pregnancy the tenth. In 7 cases of quadruplets the age of the mother was given in 6, and the mean is twenty-seven; the number of pregnancy was given in 6, and the mean is nearly three. The ages were nineteen and twenty with first pregnancies; twenty-five with third pregnancy; thirty with number of pregnancy not stated; thirty-two with a fifth pregnancy; and thirty-five with a fourth pregnancy. In one case of second pregnancy the age of the mother was not given. From a great variety of sources I have collected 43 cases of triplets (and of these I give in the subjoined tables some account). (See Table XXI.) In 40 cases the age of the mother is given, and the mean is thirty. In 41 cases the number of the pregnancy is given, and the mean is four. (See Table XXII.) It is naturally expected that our best evidence should be derived from twins, but while this is really so we have, even in these cases, to deplore the inadequacy of the data in point of number. I have not at present sufficient time at my disposal to enter into the details of the production of twins, and for these I refer you to my work on Fecundity. It is there shown that the frequency of twins increases with the age of the mother and with the number of the pregnancy, the very early ages of the mothers and the first pregnancy forming exceptions to the rule.

In a paper by Arthur Mitchell, published in the *Medical Times and Gazette* (Nov. 15th, 1862), he shows that twins are peculiarly liable to be imbeciles or idiots. The conclusions of Mitchell's paper are so pertinent to the present subject that I quote them here at length:—"1. Among imbeciles and idiots a much larger proportion is actually found to be twin-born than among the general community. 2. Among the relatives of imbeciles and idiots twinning is also found to be very frequent. 3. In families, when twinning is frequent, bodily deformities (of defect and excess) likewise occur with frequency. 4. The whole history of twin births is exceptional, indicates imperfect development and feeble organisation in the product, and leads us to regard twinning in the human species as a departure from the physiological rule, and therefore injurious to all concerned. 5. When we pass from twins to triplets and quadruplets, everything we know regarding these latter gives support to the general conclusions in question."

Besides these accumulated dangers and disasters to the children produced in plural pregnancies we know that plural pregnancy is dangerous and disastrous to the mothers. The trivial and the graver disorders of pregnancy are more common in pluriparous than in uniparous women, and the disasters and deaths in childbirth and in childbed are also more

numerous in the pluriparous than in the uniparous. Nothing can be better demonstrated than that woman is naturally or normally uniparous, and that pluriparity is an unnatural or abnormal condition connected with sterility by being observed in the sterile ages, or ages of weakness, or imperfection of reproductive power. It does not imply the desirable productiveness of health and vigour, but the reverse.

Pluriparity in a population, then, is not an indication that its social condition is as it should be. It shows, according to its amount, that marriages take place too early or too late in life; and it may be predicated of such a population that it has a correspondingly large maternal and infantile mortality, and that the reared children are not of the finest. While woman is normally or physiologically uniparous, like the mare and cow, many of the other domestic animals are normally or physiologically pluriparous, as the dog, the rabbit, and the sow; and the fertility of most birds is a sort of pluriparity.

In the uniparous animals pluriparity is rare in various degrees in the different kinds; but the extreme rarity in some, as in the mare, may to some extent depend on the circumstance that, in general, only the finest specimens at the most suitable ages are allowed to exhibit their fertility. Little, indeed, is known about them with the exactness desiderated with a view to comparison with woman. Yet we may safely assert that, among breeders of horses and cattle, the production of twins is, with a view to their interest in both mother and offspring, not looked upon with favour.

In the sheep there is such a frequency of twins, and even of triplets, that there may be some hesitation in classing it with uniparous mammals.

In the pluriparous animals, on the other hand, uniparity is uncommon, and pauciparity is an indication of reproductive weakness or imperfection, while a just degree of pluriparity is natural or physiological. It is remarked, says Spencer, by Buffon that when a sow of less than a year old has young, the number of the litter is small, and its members are feeble and even imperfect.

The domestic hen, in its fertile career, admirably illustrates the rise and decline of pluriparity, and the variations are in accord with the great law of age which holds good in women and in all living beings. Its first and its last productions are small in size, and are believed to be peculiarly liable to be addled or without yolk, or to be otherwise incapable of being hatched. In its first year, according to Geyelin, it produces only 15 or 20 eggs; in its second, 100 or more, up to 120; in its third year, from 120 to 135, and here the climax of fertility is reached; in its fourth year it produces from 100 to 115; in its fifth, from 80 to 80; in its sixth, from 50 to 60; in its seventh, from 35 to 40; in its eighth, from 15 to 20; in its ninth, from 1 to 10. The fertility rises quickly to its summum in the third year of life, and more slowly fades to its disappearance in the tenth year of life.

In like manner the bitch and pig begin their fertile course with a small number, which year by year rapidly increases; and after a few years, whose number I cannot give, again decreases, till fecundity disappears, the last production being often a premature or a dead fetus. The pluriparous animal has its best young when its progeny is most numerous. The best young may be so described, as in pups, on account of their intelligence, docility, or special talents; or they may, as in a litter of pigs, be best because they are large and easily made to grow to great bulk or weight. In the case of the bitch, it is impossible to reduce to an exact statement the value of pluriparity, but it is no doubt, very great; and while it is the case that when most in number are produced, there is also most in weight; the statement of weight of the pups gives no idea of their value. In a litter of pigs, the value of pluriparity is a simpler matter, being estimated almost entirely by weight and capability of rapid growth; and both may be very well stated in figures.

The uniparous mare has a foal which may be valued partly for bulk, especially if it is to do rough, heavy work; but the bulk of a foal bred in the racing stud is a matter of comparatively little moment; and I dare say all will agree that the nobler the breed of horses, or the higher the qualities expected in them, so is bulk in the foal of less and less importance, and so also is pluriparity less and less desirable.

We have already used estimates of weight and length of

single children as indications of fertility in woman; and if weight and length of twins were a test of paramount import, then twinning would, correspondingly, connote fertility, as 12lb. exceeds 6½lb. or 7lb. But there are higher qualities than the combined weights and lengths, and it is these higher qualities that are deficient in twins. Weight and length are valued merely as indications of general health and full development of individuals, not of twins.

Pluriparity in uniparous animals is rare, and for its study great accumulation of instances is required; and knowledge regarding it in these animals is tardily gained. Pluriparity in some common domestic animals is an every-day matter; and without any deliberate study its variations strike even the obtuse, a class often specially sensible of the pecuniary advantages of the higher degrees of pluriparity. It is the striking characters and advantages of high degrees of pluriparity in pluriparous animals that have led to the general adoption of the erroneous opinion that pluriparity even in the uniparous animals, as in woman, is an unqualified sign of fertility.

In pluriparous animals, and specially in the common hen, the quick rise and more gradual decline of fecundity is plainly observed, the climax in the hen, as in other pluriparous animals, being marked by the highest number of annual production or in a single brood or litter. In woman there is the same kind of variation, but in her it is a decline from occasional pluriparity to the production with due intervals of the best kind of single births; and the rise is back again to occasional pluriparity and hurry of births one after another.

In the common hen the rise to the climax occupies three years of life, and the more gradual decline occupies six years, according to Geyelin's data, already given. In woman the decline to the lowest, if we count roughly, from fifteen to twenty-five years of age, occupies ten years, and the more gradual rise, from twenty-five to forty-five, occupies twenty years. In the hen the rise is from 15 to 135, and the decline from 135 to 1. In woman the decline is from about 1.02 to 1, and the rise again to about 1.02. There can be little doubt that a similar rise and fall, or fall and rise, are to be found in the history of the fertility of other living things. The curve of this climax and anticlimax is not a part of a circle. Dr. Routh, in a valuable paper on "Procreative Power," published in the *London Journal of Medicine* for 1850, describes this curve, representing what he calls the inclination of procreative power, and thinks the circle is perhaps the nearest that could be selected; but the circle cannot be made to represent the figures on which he relies. He makes the age of greatest fecundity in woman twenty-six; and the climax and anticlimax may be partially indicated by the following figures, which he gives:—At fifteen years of age the figure is 22; at twenty it is 82; at twenty-six it is 100; at thirty it is 92; at thirty-five it is 74; at forty it is 54; at forty-five it is 39.

In leaving the subject of twins, it is natural to refer to malformations and monstrosities as showing weakness or disorder of the reproductive powers, but on this point I have no good detailed evidence to adduce meantime. Yet it is well known that a great body of opinion is in favour of the view, and there are many facts pointing in the same direction. In the course of these lectures I have frequently mentioned such opinions and facts, but the subject is well worthy of special study. Here I would only refer to the frequent combinations of idiocy and malformation, of idiocy and twins, of idiocy and premature or post-mature maternity, of malformation and twins, of interbreeding and malformation, of interbreeding and sterility, as combining to form an argument that may, if worked out, be found to be conclusive on this question.

Experiments in producing malformations and monstrosities in the common fowl have been very fruitful in results, and demand caution in judgment as to the potency of such influences as age of the mother. Especially interesting in this view is the recent discovery of D'Arste that mere delay of incubation, in the case of the eggs of the common fowl, is a cause of malformation in the chick.

THE Right Hon. John Bright, M.P., was installed on Thursday last as Lord Rector of Glasgow University with the usual ceremonies.

INFANTILE PARALYSIS. (a)

By CHARLES NELSON GWYNNE, B.A., M.B.,
M.Ch., T.C.D.,

Hon. Surgeon to the Sheffield Children's Hospital.

MR. PRESIDENT and GENTLEMEN,—Though I cannot give you in connection with this subject any original researches of my own, yet for various reasons it is a subject which ought to be an interesting one for discussion. The clinical features of the disease have not, till comparatively lately, been recognised, or rather differentiated; the pathology also has up to a recent period been practically unknown; and the treatment adopted, before the disease became to a certain extent understood, was either *nil*, or in many instances injurious, and even after a fairly accurate, as far as it goes, basis of its pathology had been laid, the modes of treatment suggested showed anything but a unanimous consensus of opinion. In fact, in this, as in many other forms of disease with which we are brought face to face, we have, I fear, to confess that treatment has very little influence upon the course of events, and that the issue is arrived at almost irrespective of our efforts. On the other hand, infantile paralysis is a disease which is not uncommon in the experience of most general practitioners, and it cannot fail to be interesting to find out in the course of the debate, what clinical features have predominated in the experiences of individuals present, and what course of treatment has been found by each most favourable. Amongst the many diseases that entail deformity, and Sheffield, I am sorry to say, has its full complement of such, there are none which present such sad and hopeless characteristics—to the parent whom a sad fate compels to witness it in their children, to the stranger who suddenly in the street comes across the youthful cripple with a withered arm or leg, or to the physician who has to view the same in a hospital and, in the majority of cases, to confess his skill unavailing. The name of the disease as it is usually known in this country, viz., “infantile paralysis,” is unfortunate and misleading, for it is not, as the name would imply, the only form of paralysis that occurs in children; and even if it were it is not confined to the period of infancy, but attacks persons of any age; and it is akin to a form of paralysis that is by no means uncommon in adults, to which Duchenne has applied the name of “progressive muscular atrophy.” How very little has been till lately known of the nature of this disease will be evident from the fact that it was not till 1860 that Von Heine first described its clinical features, and it was not till after 1870 that the pathology of the disease began to be understood. Our principal knowledge of the pathology of infantile paralysis has been derived from the observations of Cornil, Prévost, Lockhart Clarke, and after them, of Charcot, Vulpian, and Professor Erb.

Though infantile paralysis or acute anterior poliomyelitis, a name proposed by Professor Kussmaul, has been observed at almost every period of life, yet we cannot but recognise the period of youth as a predisposing factor. Most of us have seen cases of it in children which from time to time come under our care, but few, perhaps not one of us here, has seen an acute case in an adult. The more chronic form of the disease, viz., progressive muscular atrophy, has no doubt been familiarised to most of us, if not in private practice, at least in the wards of an hospital. If we look back and recall the history of cases that have come under our own observation, the first thing that will strike us is the apparent want of any efficient cause for the attack. I am sent for to see a child, it is probably teething, but otherwise is healthy, as far as outward appearances go, the mother tells me that she put it to bed all right and in perfect health, and in the morning on taking it out of its cradle she finds one leg is helpless, or an arm, or both. The child itself

does not seem much the worse for the catastrophe, but takes his food much as usual and does not afterwards deteriorate in health. The above is all the history which can be got at in a large number of cases, and was in fact the history, and the only history I could get in an old case of a boy named Haslam under my care last month, where both legs below the knee were paralysed, the right retaining some slight power of motion. I am aware that it is laid down that the paralysis in typical cases is ushered in with fever and restlessness, but I can only recall one case where I was called in sufficiently early enough to take note of the fever, and in the other cases that have come under my care there may have been the initial fever, but I could not satisfy myself on the point either from the condition of the patient or from the history. On this point of initial fever I would solicit the opinion of those present who have had cases of infantile paralysis under their care. Charcot regards the fever as the usual precursor of the paralysis, and most of the textbooks follow his example, but in the few cases I have seen I have failed in the majority of them to obtain any history of high temperature. After the draft of this paper was written I happened to take up West on the “Diseases of Children,” and I find he lays little stress on the initial fever, and makes it rather the exception than the rule.

From statistics gathered from various sources I find that in nearly half the cases the lower limbs are the affected parts; of the remainder the majority represented implications of the arms and legs, or arm and leg, and a very small number the upper extremity alone. There are few features of the disease so interesting in a pathological point of view as the atrophic changes that gradually supervene—the wasting or withering of the limb, which is not confined to the soft structures alone, but also affects the bones. This would suggest that portions of the nervous system are involved that preside over nutrition. Let us compare (side by side with this remark) the deformities that characterise infantile paralysis with the large number of deformities which we witness in rickety children, the latter in many instances presenting more or less partial paralysis, and the notion is apt to occur whether the deformities which characterise rickets may not be due to lesions of a somewhat different character affecting the same portion of the trophic nerve system. But this is by the way.

As regards the cause of the disease, then, I fear we must own that we know nothing whatever of the subject. All the investigators, it is true, assign some cause, such as teething, measles, scarlatina, malarious fever, convulsions, heredity, but when such a variety of wholly distinct causes are assigned which possess no feature in common, I think we are warranted in thinking that they are not causes at all, but merely concomitant or accidental. Heredity, I believe, has a distinct influence in the production of the disease; but, after all, it is only after a very loose or popular mode of expression that we can consider “heredity” in any sense a “cause.” As regards the etiology of the disease, we must, I fear, at present rest content with the very general statement that early life, and especially the period of dentition, is especially liable to disorders of the cerebro-spinal system, and as, from apparently very slight causes, we find convulsions the cause of death in the case of numberless infants apparently robust, so we see an affection of the spinal system with, to all appearance, as little cause producing temporary or permanent paralysis.

I had hoped to show you, under the microscope, some sections of spinal cords taken from patients that have been the subject of infantile paralysis, but I have been disappointed at the last moment in obtaining them. Supposing such a section to be put under the microscope, in the majority of cases you would see an atrophy or shrinking of the anterior grey substance on one side or both, and a paucity, or entire absence, of the large nerve cells, and if any remained they would probably

(a) Read before the Sheffield Medico-Chirurgical Society, March 1st, 1883.

be shrunken, and present some pigmentary changes. The axis cylinders in the same anterior cornu would be few in number and partially wasted, and their place supplied by fibrous-tissue fibrils; the capillaries would probably be numerous and large, though sometimes the reverse. The anterior lateral column would probably be smaller in diameter than on the opposite side, and the nerve fibres going to the anterior nerve roots would be deficient with some connective tissue-fibres filling their place. In fact, very much the same state of things as is described in cases of progressive muscular atrophy. Why then, I should like to know—and I would be very glad if some gentleman present would suggest—Why, in the latter disease, the affected limbs react normally to electrical stimuli; and in infantile paralysis galvanic reaction is either wholly or partially lost? Gentlemen present will please note this point. We may sum up then, the appearances of cord sections in infantile paralysis as suggesting a "sclerous atrophy of the anterior cornu of grey matter, with disappearance or shrinkage of the large motor cells, and some hyperplasia of the neuroglia connective tissue; with occasionally secondary emaciation of the adjoining white column."

Let us now turn our attention to the limbs, and first let us consider the muscles. Of course, we have loss of heat and atrophy. The first inquiry here that will suggest itself to us to make is, What is the cause of the atrophy? Is it due merely to their not being called into action? Or is the atrophy as much a feature of the disease as the paralysis, and dependent upon the changes in the nerve centre? The latter seems to be the most probable, as we see the atrophy extends to the osseous system as well, and because we see in some cases it forms one of the earliest phenomena of the disease. This suggests the question of the utility of topical remedies, such as rubbing, massage, electricity, heating, &c. Here again, in the muscle lesion, we observe a marked contrast to the order of sequences that obtain in the cognate disease "progressive muscular atrophy," for while in the former the paralysis always precedes the atrophy, in the latter the atrophy precedes the paralysis and determines the amount of it. This point I would also mention present to note, and offer, if possible, some explanation of.

Let us now examine a piece of affected muscle under the microscope, and what do we see? If we take it during the earlier period of its degeneration, we will see simple atrophy of the muscle fibres, some sarcolemma nuclei scattered in clusters between the fibrils, some loss of striation in the muscle fibres, and hyperplasia of the connective tissue; if we examine it after the atrophy has reached its intensity we will find much fatty degeneration, an entire absence in parts of muscle bundles, and a substitution of fatty material.

A curious example of the defective development of the limbs affected by paralysis infantilis presented itself at the Children's Hospital, Brookhill, some time ago, in the case of a girl, Lydia Holmes, *æt.* 5 years. At the age of about ten months, according to her mother's statement, she suddenly lost the use of the left arm and leg, not altogether, but retaining some slight power of movement. After a while she regained to some extent the strength in the affected parts, but they never reached the standard of development of the other limbs. I found on examination that the left arm and leg were both thinner than their fellows, and on measurement, that the left arm was nearly an inch shorter than the right arm, and the left leg half an inch shorter than the right leg. The hand, too, was smaller in diameter across the palm, and the same applied to the foot. She could walk fairly, limping a little, and showing evidences of weakness in the affected leg, and she could not grasp firmly with the left hand. In other respects she was perfectly healthy. She never had convulsions, nor was there any history of any illness or noticeable symptom prior to the appearance of the loss of power. There did not appear to have been any treatment whatever directed

to her case. Having alluded to some of the most interesting features in the clinical history and pathology of the disease, I now arrive at what, after all, is the most practically important to men like most of us who are called in, not so much to gratify our scientific tastes in diagnosing and observing, as to cure our patients. And here my limited experience is not comforting. Advisedly, I think that treatment does do some little good in some cases, especially in those cases where Nature is going to effect some repair of the mischief of her own accord. In such cases, by a variety of measures directed to keeping up an artificial exercise of the muscles of the affected parts, and supplying artificial heat, we may delay the degenerative changes going on in the muscular tissue until such time as the nerve centres, becoming restored to health, supply the natural centrifugal nerve stimulus. To carry out this line of treatment, a variety of expedients have been recommended. Friction, kneading, massage, shampooing, and electricity have all been recommended, and are, no doubt, useful, and a gentleman named Klemm has invented a very pretty little apparatus for beating the affected muscles. It is made of wood, and has to be vigorously applied, and when we consider that there is no loss of sensibility in this disease. I have no doubt but that its application is contemplated by the suffering infant with feelings particularly enjoyable. On the whole, friction with the hand, keeping the limb warm by a casing of cotton-wool, and the application of electricity, sum up the most rational treatment in chronic cases. A toy called the "baby-jumper," which he does not condescend to explain, is highly recommended by Dr. West.

In using electricity a good deal depends on the method of its application. First, as to the kind of electricity to employ. In bad cases we find faradisation of no use at first, for the simple reason that the muscles will not respond to it; on the other hand, in many cases where the former has failed, the application of galvanism will induce fairly strong muscular contraction, so that we may adopt it as our rule in practice to commence with galvanism, and when the muscles are so far improved as to respond to the faradaic current, to call in its assistance also.

Early in last month I admitted Edith Stocks, *æt.* 3 years, into the Children's Hospital, suffering from paralysis of both legs practically complete. In her case, too, there was the sudden seizure, but no history whatever of previous fever or indisposition. The muscles of the legs were much wasted, and the feet and legs hung and swung about like flails. I applied the faradaic current without the slightest contraction being induced in the muscles. I then employed galvanism, bringing into action first ten, and then twenty cells. The former failed, but the latter induced contractions, the legs being drawn up to the body, and the feet extended. Since that time the galvanic current has been employed at first twice a week, and afterwards daily, with, I think, some very slight improvement, but of course it is too early yet to estimate the value of the treatment. The best method of applying the galvanism is to place the anode or positive pole over the spine, at the seat of the disease, and the negative or cathode over the limb, or the nerves that supply the affected parts close to their exit from the canal of the spine. The positive, or the pole applied to the spine, should be stationary, but the negative can be either fixed over the nerves going to the limb, or moved up and down over the affected muscles—the labial method. After some months, or a year or two's perseverance in this treatment, the patient surgeon or parent will probably be rewarded by some signs of improvement. A judicious use of the induced current also will be of benefit. At the same time, the general health should attract special regard, and special nerve tonics should be administered. So far for the treatment of chronic cases where there is atrophy of the limb. In the early or acute stage more vigorous medicinal treatment should be employed. Dr. Althaus re-

commends the injection of ergotine, $\frac{1}{4}$ gr. for a child a year old, hoping thereby to cause contraction of the blood-vessels of the part, and so deplete its blood-supply. He also stimulates the muscles as they become affected with injections of strychnia. Other natural remedies in the acute stage are cupping, leeches, iodide of potassium, blisters, &c.

ON THE SOLUTION OF THE ACTIONS OF REMEDIES, AND ON THE EXISTENCE OF NERVES OF INHIBITION AS EXEMPLIFIED BY THE ACTION OF SEDATIVES AND STIMULANTS.

By HUGH OWEN THOMAS, M.R.C.S.

(Continued from page 249.)

STIMULANTS—(Continued).

BELLADONNA is now admitted to be an antidote to opium poisoning, but it has also been noticed that opium will not act as an antidote to belladonna. This is further evidence that belladonna possesses genuine stimulant properties only, as over-stimulation (poisoning by a stimulant drug) must lead to exhaustion, a condition which would certainly not be benefited by any drug that tended to arrest vital action.

The efficacy of belladonna as an antidote to opium is explicable by the fact that it possesses an earlier affinity for the vagus than opium possesses. Thus, if a toxic dose of opium be taken, and an antidotal dose of belladonna be also given, ere the opium has affected the vagus, the other drug precedes it in affecting the vagus, and thus protects the nerve rather than neutralises the coming action of the opiate. The prescribing of a combination of opium and belladonna is evidence, I maintain, of ignorance for which, at the present day, no trained practitioner has good excuse.

In the selection of drugs for the treatment of maladies, it is my opinion that more attention ought to be given to their physiological action on the healthy portion of the body, as it is the indirect or secondary effect of remedies in many instances that brings about relief to the diseased area, the latter not being susceptible to direct drug action.

The theory here advanced in explanation of the apparent divergent action of drugs will, if used as a guide to the interpretation of the data given by experimental and clinical observers, enable us to harmonise the signs that follow the action of drugs, which otherwise would appear contradictory. It is my opinion that this theory will also be of some assistance towards the settling of the open question as to the existence of "nerves of inhibition."^(a)

My explanation of the phenomena which have led physiologists to believe in the existence of inhibitory nerves is the following:—That each animal contains, stored in certain nerve-centres, a quantity of nerve force which, for the sake of illustrating my argument, the whole quantity may be reckoned as represented by a unit, this being originated and stored in several nerve centres, which I will suppose to be represented by five fractional components of the total (unit). It would not be an unreasonable supposition that, if by a drug of mechanical influence, any one of these five nerve centres was inhibited, then there might remain one-fifth more available source of force for service elsewhere, which could only be utilised and deflected along the remaining four-fifths of nerve structure. This economy of nerve force in one direction would raise the fractional energy of the remaining untouched nerve centres, so that their force would be represented by a fractional power of one-fourth of the total unit. Such a transposition of nerve energy would cause, for a time,

(a) After I had formed this opinion, it was a source of satisfaction to find that Mr. Lister had also questioned the correctness of the prevalent views held regarding the question of inhibition.

those parts to which the remaining four fractions habitually conveyed energy to show signs of excitement. And there are good grounds for believing that such nerve inhibition can be induced or prevented by drug influence, as it is patent that the simulated signs of stimulation follow the action of narcotics, certain doses producing isolated action upon certain nerves only; and the question naturally arises, why should there be a temporary excitement of the unaffected nerve-centres when no stimulation had been exercised nor extra force introduced? This excitement cannot exist without extra source of power, and as the excited nerve-centres had already their usual store, probably this sign of increased energy-excitement may have been derived by some method of deflection of store from the inhibited force being arrested from being distributed to its locality of expenditure. The preceding I believe to be the solution of the method by which the phenomenon that follows the inhibition of nerves is caused, as there has been no evidence of the existence of inhibitory nerve fibres, though their existence has been previously asserted. Experimental physiology and clinical observation both are in favour of the probability that nerve force can be distributed collaterally; and why should the store of nerve energy within a special centre, if arrested from being distributed to its usual points of expenditure, not be deflected into another centre, all being known to be connected.

It is from observation of the signs that follow the administration of drugs belonging to the class known by the terms sedatives and narcotics—inhibitory drugs—that we must seek for physiological and clinical information which may enlighten us in regard to the debatable question of the existence of nerves of inhibition, more than to the effects that result from mechanical interference with animal structures (a); not that I would totally ignore information derived from such source. If we again select opium and alcohol, both narcotics, in illustration of the views upheld in this contribution, if after the administration of a physiological dose of either of these, a careful watch is kept upon its progress across their area of physiological action, what do we observe? First one system of nerves—the sympathetic—is inhibited, and the remaining ones are excited, but as soon as another nerve-centre is reached by the narcotic and becomes also inhibited, all the other nerve-centres show further excitement, and when these have succumbed to the drug action, we have the total narcotic effect. Those who are accustomed to the habitual use either of alcohol in any of its various popular forms, or opium, or indeed of any narcotic, tell us of the pleasures they enjoy from the extra activity of the sensorium. Some even profess that with the aid of what is mis-termed alcoholic stimulation and the sedative action of other narcotics, they are, whilst under its influence, mentally and physically superior; this may be found to be true, if it could be proved that temporary drug inhibition of nerve-centres, not necessary to mental or physical exertion, did increase the nerve force available for use by the remaining unaffected nerve-centres.

Some may suppose that the action here attributed to alcohol is a justification or even an encouragement to its being habitually consumed, but this is certainly not a proper deduction to make from the theory advanced in this paper, as the habitual use of alcohol and of other narcotics by their inhibitory effect both upon the action and nutrition of the liver, kidneys, and heart, tends to produce in all persons, and in many prodigals, a diseased state of these organs. Some may also

(a) Experimental investigation has shown that mechanical interference with nerve-centres and trunks sometimes produces shock, and at other times excitement. This makes observations taken during direct interference with the parts experimented upon inconclusive. Again, in very many instances, observation as to the effect of direct interference is made while the subject of experiment is under the influence of an anæsthetic, the toxic action of which introduces another source of error.

suppose that the remarks here made in regard to the simulating of stimulation which follows the use of narcotics is also a justification for using them when pure and urgent stimulation is wanted. This would be justifiable only, if no true stimulant was known or near at hand, inasmuch that the administration of a narcotic for this purpose involves some risk and delay, as simulated stimulation is not so rapidly induced. And, again, it may be rapidly followed by the true narcotic action over too large an area, and this in a critical case may further arrest life previously threatening to ebb—especially if the subcutaneous method of the administration of remedies is practised. For instance, a subcutaneous dose of either opium or belladonna acts rapidly, commencing after a period of fifteen or twenty minutes has elapsed, one-fourth of the period required when given by the mouth, while after the introduction of alcohol or ether subcutaneously, their action is not as rapid as when given by the mouth. The practice introduced of late of injecting ether under the skin in collapse is certainly wrong, for when thus administered, its action being much more slowly developed than even when given by the mouth; if it were otherwise it would be almost certain death to the patient.
